FROM Sunday last till October next the National Picture Galleries will be open to the public on Sunday afternoons. The numbers visiting them in previous years testify as to how the Sunday opening is appreciated generally. It affords photographic assistants who are engaged throughout the week the opportunity of visiting the galleries and studying the works of the greatest masters. We call special attention to this matter here, inasmuch as at the present time assistants generally are complaining loudly of dearth of employment and low salaries. At the conclusion of the article on this subject in our issue of the 24th ult., we made the remark "that the more proficient a man is in his work the better chance he has of getting employment, and the better chance he stands of retaining it." As we then pointed out, there is now little to learn in photography, so far as the mere exposure and development of dry plates is concerned. The chief thing, however, to learn is lighting, posing, and treatment of the sitter in the studio, and, in the case of landscape work, the selection of subject and the proper conditions of light at the time it is taken. It is in these matters that the skill of the present-day operators is gauged, and it is in this direction that first-class houses complain of the difficulty of getting really good operators, even at very liberal salaries. During week days *employés* have very little opportunity of visiting the picture galleries, but now they have, on the Sunday afternoons, but how many do so for the purpose of

improving their minds in what is really the most important part of their business? The National Gallery contains the best works of the old masters, the Portrait Gallery is devoted entirely to portraiture, and the Tate Gallery, on the Embankment, to the works of modern painters. No photographer visiting any of these exhibitions can well come away without profiting something in the most essential portion of his work, choice of subject, lighting, posing, &c.; but, as we have just said, how many avail themselves of this chance? We recommend these remarks to those who really wish to improve themselves in art matters and their condition in life.

\* \* \*

MESSEURS. CADETT & NEALL, of Ashted, announce that they are now placing measured orthochromatic light-filters on the market. These light-filters are adjusted for the Rapid Spectrum plates, and are designed to enable paintings, flowers, landscapes, and any coloured subjects to be rendered in accordance with their colour luminosities. It is pointed out that the light-filters are of no value with any other colour-sensitive plate than the Rapid Spectrum. Each light-filter is tested by Mr. Cadett before being sent out, the testing instrument being Captain Abney's colour sensitizer.

\* \* \*

LAST week we alluded to the fact of the arrest of three students with photographic apparatus, as illustrating that the spy scare had not yet subsided in France, and that it was not confined to the frontiers. Since then there have been other arrests of so-called suspicious individuals, out of which several of the French papers have made much sensational capital. All this tends to bring the spy scare to an acute stage, and necessarily also bring about additional vigilance and officiousness on the part of the police and other authorities. Hence this further warning to English photographic tourists in any part of France. We should specially advise every tourist with photographic apparatus in France just now to be provided with an English passport, which may be obtained at the Foreign Office without difficulty and at a nominal cost. An English passport will not, of course, keep its holder out of a difficulty, but it will be of great service in helping him out of it if he inadvertently gets into one. Passports are not now necessary in France, Germany, Belgium, or Holland, but it is well for photographic tourists in either country to be provided with one. Once obtained, it does for all time and all countries.

\* \* \*

THE Emperor Francis Joseph, it is stated, has conferred on Herr Leopold Horowitz, the famous Vienna portrait painter, the medal of Honour for Art and Science for his posthumous portrait of the late Princess Elizabeth. This exceedingly fine portrait is now in the Spring Exhibition at Vienna, where it is said to be the chief centre of attraction. The portrait was painted entirely from prints and photographs, and we believe the artist had fewer of these to work from than he would have done of any other Royal personage in Europe. The late Empress had a very decided aversion to sitting for her portrait—more so than the majority of Royal personages, who, as a rule, are rather pleased than otherwise for their portraits to be circulated amongst their subjects. Although so averse to her own portrait being taken, the late Empress took a great personal interest in photography and all pertaining to it; therefore it is a little surprising that there are so few photographs of her in circulation.

## FILM TROUBLES.

## II.

BEFORE leaving the subject of frilling, it will be well to point out, after again emphasising the danger to be apprehended on this score from films puckered or creased through crooked rewinding on the spools, that, when a number of spools are to be developed at once, it is always advisable to ascertain if they belong to the same batch. From the most noted makers batches liable to frill occur; hence, if a trial spool be all right, no trouble need be anticipated, while, if it frill, forewarned is forearmed, and it must be a very bad sample the frilling tendencies of which cannot be kept under once they are known to exist. It will, of course, be remembered that the evil usually occurs in washing after fixing.

From washing, the next step is drying. The makers recommend that films be soaked in a weak solution of glycerine before they are put to dry. For convenience and handiness in printing operations this is an incontestably valuable plan. Still, some old silver printers shudder at the very thought of any such treatment. "What!" they say, "soak a film in glycerine before printing? Why, it is hard enough to keep a film dry under ordinary conditions, to say nothing about making it damp on purpose." To a certain extent they are quite just in their strictures, as we well know from the many prints stained with silver that are brought before our editorial notice. But with care in seeing that the films really are dry before putting them in the printing frame, and that P.O.P. or collodion paper only is used for direct printing, disasters will be few; but to use film negatives at all, or printing more than a copy or two (and that is unwise), or to use them once only when glycerined, if albumenised paper is the medium chosen, is simply to court disaster. Silver stains sooner or later are almost inevitable. We have just alluded to the need for care being taken always to see that the films are dry before printing, and this is by no means a mere *façon de parler*; a glycerine film looks dry long before it really is so. There is no doubt the large majority of spool-users employ glycerine in the way we are discussing, but, where a determination to avoid it exists, the drying will be a difficulty. We have seen it best overcome by rolling the spool (film out, of course) tightly round a long wooden roller, securely pinning the corners by drawing pins. When dry and kept in a moderately cool place, rolled up, film outwards, little trouble will be experienced.

There is one point in regard to the setting off of silver on to the film from the printing paper that should be noted; all risk can be obviated by a preliminary varnishing of the gelatine surface with one or other of the many varnishes now to be had for the purpose, the celluloid varnishes being perhaps the best, though the smell of the amyl-acetate solvent is much objected to by many. It is out of question to attempt to pour the varnish on and off after the fashion of the wet-collodion expert, but with little skill a sufficiently even covering may be given with the use of a broad camel's-hair brush.

In connexion with the drying of negatives, a timely caution may be of use. When a print is wanted quickly from a newly made glass negative, it is a common enough plan to soak it in one or two changes of spirit, put in a current of air, or blow upon it with a pair of bellows, and have it dry in half an hour. This plan is entirely to be eschewed in the case of film negatives, as, if so treated, they curl and pucker to such an extent that it is impossible to get a print of any sort from them. If by any chance any of our readers should have essayed this

mode of drying, with its inevitable sequence, he may, however, still get a print by putting the film between two glass plates, and, placing it in a copying camera, get a developed print fairly sharp if he stop the lens down pretty freely. We have seen a first-rate print from a hopeless wreck of a film negative obtained this way.

We have one final caution to give with regard to film negatives. Those accustomed to the handling of glass negatives must not imagine that celluloid will bear the same treatment as glass, nor that thin shavings of that material (which is, indeed, an exact description of spool films) are equivalent to glass. They are practically as transparent as glass, but there their likeness ends. They will not break, but, *per contra*, the film has not the same tight hold as on glass, and the contractile nature of the gelatine twists and curls the celluloid under very slight provocation. Therefore, all film negatives should be kept in as cool a place as possible, and never allowed to lie loosely about, as, if such care be not taken, they may become unmanageable cellulosidal curls and contortions; while, if they are allowed to remain in the sun for any length of time, the film may actually become detached.

**Dr. Russell's Experiments on Hydrogen Peroxide.**

—Though the subject is one of such surpassing interest that it is too important to pass by in small paragraph, we may yet call attention to the most remarkable field of experiments opened out by his researches. All the hitherto occult causes of fogging put down to electrical excitations, sunlight, &c., are capable of explanation by the one simple cause, the production of peroxide of hydrogen, the action of which upon the film produces effects similar to those of light action. The objection that this chemical substance could not pass through solid bodies is entirely done away with by Dr Russell's further experiments in this direction. He showed that the peroxide was capable of passing through a variety of solid substances, and that many bodies could imbibe it, so to speak, and continue to give it off for a lengthened period, so as to act upon the prepared plate.

A VERY delicate reaction to indicate its presence, or otherwise has recently been described in the *Chemical News*, by Mr. Edgar S. Barralet, and may be of great use in connexion with work in Dr. Russell's direction. The delicacy of the new reaction is its great charm, and some idea of it may be formed when it is stated that it is only when the peroxide is present in very small quantities that it may be pronounced with certainty to exist in the tested liquid. When the latter is so dilute that no reaction could be discovered from potassic bichromate, or permanganate, or calcium hyperchlorite, or other oxidising agents which might be confused with peroxide, the latter, if present, is shown in a pronounced manner. The following is the simple process: Solution of potassium ferrocyanide is added to a solution of a ferrous salt to the production of a pale blue precipitate. Peroxide would oxidise this to the dark blue, "Prussian blue," and, when present to the extent only of 1 in 165,000 parts of water, is capable, if about fifteen drops only are taken, of intensifying the pale blue of over half an ounce of the pale blue precipitate. The latter should be either freshly prepared or kept in a bottle under a layer of petroleum.

**Persulphate of Ammonia.**—Those who employ persulphate of ammonia for reducing negatives, especially if the latter tend at all in the direction of delicacy, should adopt a precaution which may often save them at least some uncertainty. When a fresh solution of the persulphate is made with ordinary water, or even with rain water, it will generally, when first applied to a film (unless the latter has been very imperfectly washed and still contains much hypo), at once form a dense white flocculent precipitate, part of which is suspended in the solution, part loosely deposited on the surface of

the plate, and part again enters into combination with the image. This is due to the salts, chlorides, carbonates, and sulphates contained in the hard water, which, directly the persulphate begins to reduce the silver, attack the latter and throw it down. The portions suspended in the solution and deposited on the plate are not of much moment except in so far as the latter may, to a slight extent, change the appearance of the image temporarily, and so lead to an incorrect judgment of the progress of the reduction. But the third portion, which enters into combination with and bleaches the surface of the image, plays a more dangerous part. Not only does it perform a certain amount of reduction on its own part that is not evident until the "stop bath" of sulphite of soda is applied, but it covers the surface metallic image with a thin casing of chloride and what-not, and stops, or partly stops, the redeposition of silver on the surface that causes the selective action of this reducer, and prevents the annihilation of the fine details. Sulphite of soda, it must be borne in mind, is a fixing agent, second only to hypo in its power, and, besides instantly stopping the reducing action, this solution performs the equally useful part of freeing the reduced film from chloride and carbonate of silver. The actual reduction ensuing on this operation may not be great, but it may easily be sufficient to just spoil the gradations of a delicate negative. But the other effect is more serious, and entirely alters the character of the reducing action, robbing it of that peculiar selective power which renders the persulphates so valuable. To prevent the formation of chloride and carbonate of silver in any of these ways, it is only necessary to immerse an old and useless negative in the solution before use for its legitimate purpose, and to then filter out the precipitated silver.

#### **The Value of Sulphite of Soda as an Application to Negatives after Fixing.**

While on this subject, we may perhaps be allowed to express the opinion that the "stop bath" of sulphite of soda should invariably be used after persulphate of ammonia. We know it has been said that free and copious washing in plain water will serve the same end just as well, that is, will arrest further action of the reagent; but even with this we do not agree—though that is a comparatively small matter in our estimation. Granted it does, the function of sulphite still remains of eliminating or neutralising the somewhat prolonged action of a very dilute solution of silver upon the gelatine. Even after the treatment given above, the solution of persulphate in use soon becomes opalescent, milky, and gradually deposits a considerable quantity of white flocculent matter. It becomes, in fact, saturated with sulphate of silver, which, not being a very soluble salt, is soon thrown out of solution. Speaking from memory, we believe the solubility of the sulphate at ordinary temperatures is under two grains to the ounce of water, so, as we cannot expect handsome tabular crystals like the nitrate, we must accept the powdery flocculent substitute referred to; but, if the saturated solution be weak, it is still powerful for evil, as any one may soon learn by dropping a few drops of this opalescent mixture on a valuable engraving. If it acts with fair rapidity upon paper, it is very certain that its effect on gelatine will be not less marked, hence the integrity of a negative reduced with persulphate is a doubtful question in the absence of the use of sulphite or hypo, though the former seems in every way preferable. The first action is to convert the soluble sulphate into insoluble sulphite, which is afterwards removed by a mild form of fixation, the solution of sulphite of silver in sulphite of soda having, so far as we are able to ascertain, no action on gelatine or organic substances, and it is not sensitive to light.

#### **The Action of the Soluble Hyposulphites of Soda and Silver on Films and Paper.**

*Apropos* of the action of soluble silver salts on negative films, we may mention that we have often, when discoursing on hypo eliminators and the importance of removing all possible chance of such effects as we have found arising from the action of silver salts, had it pointed out to us that the double salt formed in the process of fixing, and known as argento-sodic hyposulphite, is itself a soluble silver salt, is formed in

the pores of the film itself, where it must necessarily act for some time, and is finally only "evicted" by means of plentiful washing, and that, according to our theory, this should be as bad as are other soluble salts of silver, if not worse, on account of its composition. Quite true so far as the first part of the argument is concerned, but utterly wrong as regards the finish. In order to work harm, the soluble salt or solution must have an affinity for organic matter, must, in fact, have a tendency to combine and form a silver compound. Nitrate of silver, for instance, or any of the simple silver salts, the haloids, or carbonate, or insoluble organic salts when dissolved in ammonia, in fact nearly all solutions containing silver in solution will form such combinations when applied to paper, linen, or similar substances, and, if they once make contact, it is practically, we may say absolutely, impossible to remove the effect by means of simple washing. Sooner or later, in the dark and protected from moisture, but much more rapidly under the action of light and damp, discolouration takes place, as only too many photographers of an earlier era are well aware; but the double hyposulphite of silver and soda has no such tendency. Coated on to paper, even in concentrated solution, it is insensitive to light, though exposure to the atmosphere oxidation, in fact, quickly turns it yellow. We have purposely separated the two double salts of hypo and silver for the special purpose, and find that, though both are easily oxidised and made to deposit sulphide of silver, a concentrated solution of the "sodic" salt, which alone should be present in a properly fixed print, will show not the slightest change beyond general yellowing after weeks of exposure to light. Further than that, if a sheet of albumen paper, dipped in this solution and dried, have one-half of it again dipped in four or five changes of pure water to remove the salt, it will bear free exposure to the open atmosphere without any change of colour for months.

#### **Another Photo-astronomical Achievement.**

Photography among the stars has scored another success. We read that Professor W. H. Pickering, of Mr. Lowell's observatory at Flagstaff, Arizona, has discovered, by photographic means, another satellite of Saturn. It is only a telescope of very large aperture, if any at all, that could render this new satellite visible. The photograph showing this most recent stellar *débutant* was presumably taken at Arequipa.

#### **THE BATTLE OF THE TONING BATHS.**

By the last batch of issues of THE BRITISH JOURNAL OF PHOTOGRAPHY that has come to hand at the remote place whence I write, I see that the battle of the toning baths for gelatino-chloride, gelatino-citro-chloride printing papers, known by various trade names, some of which names are execrable, rages as furiously as ever. It mostly refers to the old question of mixed toning and fixing *versus* separate.

What I have just read makes me wish to put before your readers a method of combined toning and fixing which reduces the producing of gelatino-chloride prints to the greatest simplicity possible. I have published the process before now, in fact when I first worked it out just about twelve years ago, at which time the paper referred to was very little used, there being, if I remember rightly, but one brand on the market. I could not then, however, say of it what I can now, namely, that it gives more permanent results than any single bath that I have ever used, or than any separate baths either. Of course I speak comparatively when I use the word "permanent," for no silver print can be called permanent in the absolute sense of the word.

When it is said that some single print on silver paper—albumenised for example—has kept for thirty years without showing any sign of falling off, no proof of permanency in any sense of the word is given; but when it is stated, as I can state of prints toned and fixed by my bath, that on various kinds of paper, between the time of twelve years ago and half a year or so since, many hundreds in number, not one has, to my knowledge, faded, and only a few have "gone yellow in the whites," at least a strong presumption of comparative permanency is made out.

Another reason for presuming permanency, in the case of the results of the bath that I advocate, is that the prints fade less under the influence of a bichloride of mercury solution than those toned by other baths, and this, I believe, simply for the reason that more gold is deposited. The

bath is not a cheap one. It takes more gold to tone a sheet of paper with it than with any other bath I know of; but it is many years since I stated, in these columns, the opinion that toning baths economical in gold were by no means to be encouraged, but, on the contrary, those that used the most gold, so long as that gold was all deposited on the image.

The general principles of the particular bath I refer to are as follows:—

1. A very strong solution of hypo, so as to make sure that the prints are thoroughly fixed before the toning is finished.
2. A comparatively strong solution of gold, otherwise the toning is intolerably slow.
3. The neutrality or slight alkalinity of the bath, to be maintained even if an acid paper is used.
4. The same solution never to be used twice.

My formula has been modified from time to time by way of improvement, and has also been more or less altered for different kinds of paper. I have not with me the notes of all these modifications, but give below instructions for the use of what may be considered a typical bath. The paper is to be printed a little deeper than for most toning baths.

The following is made up:—For each sheet of paper 22×17, or proportionately for other sizes, the following bath,—

Hypo.....	2 ounces.
Borax.....	80 grains.
Chloride of gold.....	2 „ *
Water, up to .....	8 ounces.

To this is added, say, thirty or forty grains of powdered chalk. This does not dissolve unless the bath tends to become acid. Otherwise it remains as an inert powder at the bottom of the dish. It might seem that such a powder would be likely to “dirty” the faces of the prints; but, as a matter of fact, it does not.

The bath should be used at as near 65° F. temperature as possible.

The prints are taken unwashed, as they have come from the printing frames, and are placed dry, face downwards, in the solution. The rest of the process is the usual one. The colour is judged of best by looking through the prints. As all sensitiveness is lost in a very short time, generally about a minute, daylight may be used; but I should fear to use it very strong lest the hypo-silver solution should be acted on by light on the surface of the paper. The time of toning should be about ten minutes.

I generally tone to a very deep brown. A purple can be got with some papers, but I have very seldom, in fact, I suppose, I should say never, been able to get a good actual black.

The quantity of solution for given area of paper is so small that there is, say, only half that originally mixed when a batch of prints has been toned, but this depends greatly on the thickness of the paper; of course, this is worth keeping for residues by those who work on a large enough scale to make gold residues a matter of consideration. A first washing water would certainly also contain some gold, but I have never gone into this refinement. Of course, a thorough washing is needed afterwards, and a hardening bath may be used if it is found necessary.

I ought to state that a couple of years or so ago I sent a sample of prints, toned by the process I have described, to one of the makers of printing-out papers, having, I believe, a very large sale. The firm answered to the effect that the tone was admirable, but that the whites were impure—were yellows, in fact, not whites. Well, I could not see the yellow on simply looking at the prints, nor could any of several people I referred to see it, though one of them was a professional painter.

We all could, however, see a slight yellow tinge by contrast when a sheet of pure white “double cream-laid note paper” was superposed over one half of the print. On, however, washing, fixing, washing again, and drying a piece of the very same brand of printing-out paper, there was no comparative yellowness to be seen as regards the prints; but *this paper itself* was slightly yellow in comparison with the pure white note paper. It is true that the printing-out paper was not brand new in either case. Brand new printing-out paper is not to be had in the Far East; but it had not been kept for nearly the limit of keeping time mentioned by the makers.

\* This quantity is variable. In the first place, the so-called chloride of gold of commerce is very variable as regards the quantity of gold contained. I assume here the use of the best make, containing very nearly fifty per cent. of metallic gold. Then, different papers need different quantities of gold, and still again it is evident that a delicate vignette needs very much less gold than a print with dark shadows, the image extending to the edge of the paper. The matter is very simple, however. If two grains involves very slow toning, the quantity is to be increased. Three grains is nearly always sufficient.

I may mention that the makers stated their inability to tone with my bath at all. The reason was simple, they had used just four times the quantity of water that I recommended! I have used a great deal of their paper since, and have not altered my concentrated bath.

As to yellowness again. I cannot consider a yellowness so slight as to be imperceptible except by comparison with an exceptionally white paper to be of any consequence at all. Indeed, I know no reason why yellowness should not be encouraged in many cases, except that the yellow shade so often seen on old silver prints is an unpleasant one.

A pure white paper is generally avoided in the case of etchings, photo-gravures, and in many other cases of art work. The large quantities of paper exported from this country (Japan) to Europe and America are none of them pure white. When Mr. Mortimer Menpes was in Japan a couple of years or so ago, he examined all samples of Japanese paper he could get hold of, and chose for water-colour work one with a decidedly yellow tinge.

I may say that, in the few cases in which prints toned by my bath have been turned out “yellow in the whites” or have become so, it has been because there has not been enough hypo in the solution, or that the prints have been allowed to stick together. I think there has not been a case of this yellowness when the manipulations have all actually been my own.

I have known no case of double toning except in attempts to get a pure black—attempts which, as already indicated, have been failures.

W. K. BURTON.

#### A NOVEL MODE OF GOLD REDUCTION.

We have often inveighed against the supineness of so many photographers in the matter of collecting hypo residues, and we have every reason to believe that it is still most rare to find this collection to be carried out. “Oh, it is such a nuisance to worry with pieces of zinc,” or, “Oh, we can’t do with the smell from the use of sulphide,” are the replies we continually hear. We should again point out that, from the hypo used for fixing gold-toned prints, the silver is frequently worth three or four shillings an ounce instead of the twenty-seven or eight pence obtainable for the pure silver itself. The cause of this difference is the amount of gold which is carried in to the fixing bath. The question arises, Could this gold itself be extracted without any trouble and leave the silver?

Some time ago the reply would have been in the negative, but recently an account has been published describing a method of gold-recovery from cyanide solutions which is largely used in Australia. The actual chemical operations involved are, so far, quite unknown, but in practice the recovery is a success, but costs one shilling and eightpence per ounce of gold. The liquid containing the gold is passed into tubs holding about half a hundredweight of charcoal. The gold then becomes deposited upon the charcoal, and, when a sufficient amount of liquid has been treated, the charcoal is burnt, and fused with borax to double the amount in weight of the ashes produced. At the mills where the process is in operation, as much as 10,000 pounds of charcoal are in operation at once. If, now, where the printers or their principals will not have the hypo treated for silver, surely there would be no difficulty whatever in letting the liquid run into tubs of charcoal, and periodically collecting the latter. It may be estimated that gold equal in value to the silver wasted would at any rate be collected if the plan were feasible with hypo as against cyanide.

#### KROMSKOP PORTRAITURE.

ABOUT a month or six weeks ago I equipped myself with the necessary apparatus for working the Ives process of photography in natural colours.

I was told by professionals (I myself am an amateur unknown to fame) that portraiture by this process was most unsatisfactory, owing to the sallowness of the complexion and want of sufficient colour in the cheeks, lips, &c.

But, portraiture being my hobby, I determined to try it, having an idea that the defects mentioned might be remedied by ordinary retouching with a lead pencil on the negative.

I tried, with results so satisfactory that the Photo-chromosome Syndicate’s officials were good enough to express themselves as being quite delighted with them. They are, at all events, good enough to justify me in thinking that there are very great possibilities in the process, for the little pictures have all the good qualities of photographs,

including that of likeness, which few paintings can approach, and, in addition, the delicacy of texture and of colouring of a good miniature.

The Ives process must be pretty well known by now; but, in case any of your readers are unacquainted with it, it is essential that three separate negatives are taken through screens of the three primary colours. (Apparatus is on the market for taking these in the simplest possible manner on one plate.) From these negatives three transparencies or positives on glass are printed, which, when mounted and placed in the instrument called a kromskop, are exactly superimposed, and each is illuminated by appropriately coloured light. If the relative exposure has been correct, the effect is an absolutely truthful representation of the natural colours of the objects photographed.

The three negatives are, of course, colourless, as also the transparencies made from them; but, for convenience sake, I shall refer to the negative made through the red screen as the red negative, to the transparency made from it as the red positive, and similarly for the green and blue.

I mentioned above that where this process has failed for portraiture hitherto has been in the sallowness of the complexion, &c., and it is without doubt true that, although you may get all the colours of the dress and surroundings absolutely true, the flesh tints will appear pale and colourless. Why this is so I am not prepared to say. Possibly artists have so accustomed us to flattered complexions that it has grown to be a habit with us to expect them.

The remedy, in the Ives process, lies in retouching.

Ordinary retouching can be carried out in the usual way on all three negatives equally. When that is done, retouching for the alteration of colour commences.

The principle is simplicity itself. Adding density to any portion of, say, the red negative makes that portion of the red positive lighter, and therefore, when put into the kromskop, it will let through more red light. In other words, increase of density of any portion of the red negative means an increase of red in the corresponding portion of the picture.

The sallowness of the complexion vanishes therefore when you put a bright spot of retouching on the cheeks and another on the lips. Similarly, the blue of the eyes (if they happen to be blue) can be increased by adding to their density on the blue negative.

If density is added equally to two negatives, the result is an increase of the combination of those two colours; for instance, add to the red and green, and you will get more yellow; add a good deal to the red and rather less to the green, and you get more orange, &c. Density added equally to all three negatives gives more white.

It is very difficult to judge exactly how much colour the retouching will give, but this is not a serious drawback, for it is a good plan to put rather too much on the negative, and take out the excess by retouching the positive.

All that has to be remembered is that retouching, say, the red negative adds to the red in the result; retouching the red positive subtracts from the red in the result.

It will generally be found that a portrait is more becoming if the whole of the picture is slightly redder than nature. This can be accomplished in many different ways, e.g., by giving a slightly longer proportionate exposure to the red when taking the portrait; by intensifying the red negative; by reducing the other two; or by intensifying or reducing the positives as necessary. But perhaps the simplest plan is, when making the transparencies, to print the blue and green for a few seconds longer than the red. It is obvious that errors in the original proportionate exposure can be corrected in the same way.

The one great and unavoidable difficulty is the very long exposure necessary, for the sitters must, of course, remain absolutely still while three negatives are made. Speaking roughly, it will be found that the exposure for the red will be forty to sixty times that which would be given with the same plate, light, and stop for a monochrome portrait, and the other colours will be in proportion. I have got very satisfactory negatives by electric arc light, using a Dallmeyer quarter-plate portrait lens at its full aperture,  $f/2.8$ , with exposures of thirty-five seconds for the red, twenty-five for the green, and ten for the blue, on a Cadett special rapid spectrum plate marked H. & D. 75.

I have no studio, but, under favourable conditions, by daylight, these exposures could be very much reduced; and, further, Messrs. Cadett & Neall make much more rapid plates than the one I have quoted. They have just supplied me with some marked H. & D. 111, and with a small number marked H. & D. 218, these latter being about three times the speed of H. & D. 75.

A further difficulty is that, owing to the very small size of the

pictures, the retouching is very delicate work. My kromskop is of the pattern known as the Junior, or non-stereoscopic, and the pictures are only about  $2\frac{1}{2} \times 2$  inches. But the Photo-chromoscope Syndicate have just made me specially a multiple back and colour screens for plates of  $9\frac{1}{2} \times 4\frac{1}{2}$ , or for three-quarter plates side by side, and they are building me a special kromskop, which will take this size, quarter-plate, either vertically or horizontally. I understand they contemplate later on making this size for the market.

In conclusion, I should like to point out that, as I have only been working this system for six weeks, and that fitfully, I make no pretence to be considered an authority on the subject, but I hope that my remarks may prompt more experienced photographers than myself to try it, and communicate their experience to your columns, whereby I shall be the gainer.

L. WALKER MUNRO (LIEUT.).

### FOCUSsing BY SCALE.

SINCE the article on focussing by scale appeared in our issue of the 3rd ult. we have received several inquiries as to how the scale is to be verified, as we recommended it always should be, in hand cameras of the magazine type. The obvious way to do it is to place a piece of finely ground glass in the position occupied by the plate and carefully examine the image upon it, at the corresponding different distances marked on the scale, with a magnifier. But that is not always possible with some cameras of this class. It may, however, be done by a "trial-and-error" method as follows. Set the pointer at the infinity mark and take a negative of some distant object, then rack the camera out a trifle, say the thirty-second of an inch or a little more, and expose another plate, and then a third with the pointer a similar distance within the scale mark. Then develop the plates. If the negative, with the index set to scale, is the sharpest of the three, it may be taken that the scale is accurately adjusted for infinity. But it must not be assumed that, because the scale is accurately marked for one distance, it is so for all. Hence other trials are necessary. Now place some object—say small printed matter, or better still a watch dial, at a measured distance corresponding with the shortest marked on the scale, which we will imagine is six feet, and expose three other plates, the one with the pointer adjusted to the six-foot mark, the others; the one with the index set a little within, and the other a little without it. If, again, the negative with the pointer at the mark is the sharpest, it will be clear that this scale is right for infinity, and also for the nearest distance. It is well, however, to verify the scale for a middle distance in the same way in order to make sure that the scale is accurate throughout. If the scale for infinity, the nearest and the midway distances are found to be correct, it may be assumed that it is for the other distances. In making these tests it is advisable to make them with a stop in the lens of the size next that of the full aperture.

This trial-and-error method of testing possesses some practical advantages over the ground-glass way, inasmuch as, if the chemical and visual foci of the lens are not coincident, which they are not in all of the compound lenses with which some cheap cameras are fitted, the sharpest focus point is arrived at. That is not the case with the ground-glass visual test. We have here assumed that glass plates are used; but, with cameras with rollable films, the want of sharpness in the negatives may sometimes be due, not to errors in the scale, but to a buckling of the film, or its not laying flat in the focal plane of the lens. Therefore in this instance the blame should not be laid on the scale, which may be rightly marked. Rollable films of celluloid that have long been stored in a warm place contract more at the edges than they do in the middle; hence, when in the camera, they do not lie flat, but bulge in the centre, and thus do not do the lens justice, though the scale be accurately arranged.

### LIVE, AND LET LIVE.

To limit an exhibition to some particular branch of Science or Art should not, of necessity, cause embarrassment to a selection committee. But it cannot be denied that opportunity for discernment and judgment arises where the scope of an exhibition is not a very wide one. Wide indeed is the field of Art, and many and diverse are the channels along which it works. While all pictures do not exhibit Art, Art exhibits all kinds of pictures, produced by all kinds of means. So that the selection committee of an Art exhibition would not be long in deciding upon the eligibility of a thing, however much that same committee might differ on the merits of that thing to be chosen.

The scope of a photographic exhibition, however, is not, of course, so wide. An exhibition of photographs is held to mean an exhibition of prints (whether viewed by reflected or transmitted light), produced by photographic methods. The selection committee of such an exhibition should therefore, strictly speaking, reject any print which did not fulfil the above condition. Governed as it is by the objects of the exhibition, the committee should, still speaking according to the literal meaning of things, reject any print which is not produced by photographic methods, that is to say, by the action of light, however æsthetic the result might be.

Now, year by year, criticism of the action of selection committees of photographic exhibitions waxes louder in sound and greater in quantity. More and more complaints are heard of pictures being hung in which some of the work is not performed by the action of light. First of all, we have the uncompromising hostility of those who taboo what is called "faking" by some, "control" by others. Then, in a less complaining tone, we have the challenge of the school whose spokesmen limit legitimate "faking" to the production of that which cannot be produced by what, for convenience, may be styled *ordinary* photographic methods. All this criticism is perfectly natural. It is the inevitable accompaniment of efforts which seek to make photography pictorial instead of merely topographical. It evidences the battle which has been for some time proceeding, with a somewhat spattering fire, between the Old School and the New. This battle is really a contest between a rigid regularity on the one side and mobility on the other, and, as usual, there is something to be said for both sides. It is certainly obvious that an exhibition containing a large amount of work which has not been produced by photographic methods is not exactly a regular photographic exhibition. Is it unreasonable, then, to maintain that in a photographic exhibition all the prints should have been produced by photographic methods alone? We cannot brush aside, as if it were merely *persiflage*, a certain remark which has been made, that where a print produced from a landscape negative, combined with a sky invented by the artist, is admitted as a photograph, it would be equally sensible and proper to allow hanging room to a print from a cloud negative combined with a landscape invented by the artist. On the other hand, to place a ring fence round the field of photography looks rather like a *manœuvre* to keep those who have the ability to extend that field within the narrower limits of those who have not. To drive workers within those limits, and to keep them there, would inevitably stop the production of what cannot be denied is something cleverer than topographical photography. It is unwise to prevent effort from working upwards.

Various, indeed, are the attempts to define and declare what is legitimate photography. Total non-interference with the operation of lens and chemicals is simple if unambitious. Between that and following one's own disposition to produce from a photographic basis the best that hand and brain can evolve, without showing any great particularity as to the methods employed, there is a great gulf fixed. The claim to create any effect which did not exist when the plate was exposed, so long as that effect is produced by light action, is an attempt to regularise the position of prints which contain more or less artificiality.

It is unfortunate, but true, that the most unfettered work above mentioned gives rise to some amount of misgiving to the reflective person who views its consummation on the walls of a photographic exhibition. Ought it to be there? We cannot save our conscience, as we may when we examine a clever example of "shading down," or a landscape produced by the neat combination of two negatives each taken miles away from the other, by comfortably saying, it is all done with light for a medium. What can we say about those skies which owe their invention to the brush?

It does not seem generally recognised what the growth of the lately revived process of producing a print from a photographic negative, now called the gum-bichromate process, actually means. We have in this practically new method of printing from a photographic basis a power more plastic to the touch, more responsive to the wishes of the worker than any of the generally used processes. It transforms the impersonal into the personal. It can change a photograph of glaring mid-day, full of microscopic detail, absolutely deficient in chiaroscuro, into a picture of the tender evening glow, containing broad masses of light and shade, where the valuable is enhanced and the worthless ignored. Compared to gelatino-chloride, it is as a simple melody on the violin is to the metallic precision and stridency of a piano organ grinding out, with variations, the "Ave Maria" from the "Cavalleria Rusticana." Brought into the world between forty and fifty years ago, it failed to please the more utilitarian and less sentimental photographic world that stood around its cradle. Thus it was stifled, but not quite killed, scotched, and not destroyed, to be revived when men and the times were more willing to nourish and encourage it. Is it to be considered the mere ephemeral fancy of a few restless novelty-hunting dilettantists? It can hardly be that. It seems, on the contrary, to be a substantial asset in the property of the earnest worker, a power to be used in all seriousness. It supplies to seekers after a vehicle for their best imaginings something more capable of answering their expectations than any process yet presented to them. Gum bichromate is not the plaything of an hour, but a growing force which will influence the photographic school of the future. There are many who have not the technical ability to draw all they see and all they feel,

and who find that the ordinary methods of photography, while clever enough in one respect, want capacity in the other. Gum bichromate assists such people as these, not only to record their sight, but to register their sentiments.

The influence of gum bichromate upon the method of completing the work commenced in the camera is, and will be, in the direction of supplementing that work by extra-photographic treatment. It will bring to a crisis the much-vexed question which has never been settled, which perhaps, on its merits, never will be settled, that is, the question as to what may, and what may not be, done by extra-photographic methods in producing a print whose genesis is in the camera, which will not deprive the consummation of the name of photograph. When one tries to draw hard-and-fast lines, one is brought face to face with bewildering inconsistencies and anomalies. Retouching a print is held to create a flaw in the title of that print, but retouching a negative does not prevent you from producing an incontestable photograph therefrom. While these two views can be held by the same person, it does not certainly seem easy to settle the matter on a sensible basis. Better far, it seems to me, to give up trying to settle the matter on its merits altogether.

It is not impossible to get the hanging committee of a photographic exhibition to accept a print in which the whole of the sky has been invented, by means of the removal here, and the non-removal there, of pigment from the surface of the paper with a brush. I should have no hesitation myself in submitting such a print for exhibition so long as it was not expressly forbidden by the rules and regulations of that particular exhibition. There is no secret as to the possibilities of gum-bichromate printing, and no concealment of the methods employed in its practice. If my print were accepted, it would imply, not that the committee were deceived, but that they took a broad view, and did not think they would be justified in relegating to obscurity, simply for academic, not to say pedantic, reasons, what was worthy of being hung among prints produced wholly by the action of light. It would be, indeed, lamentable were the few extremists to have their own way, and gum bichromate sent to Coventry, or, as the most vehement would have it, to Jericho; for this reason, that, whatever it may be from the point of view of photography, there is more art in a gum print than in a gelatino-chloride.

Looking at the matter dispassionately, the grumblers must be allowed to "possess a *locus standi* so long as the field of photography is *strictly* limited to what is *purely* photographic. I do not profess to have discovered how they can be persuaded into granting an indefeasible title to such prints as this article directly refers to. One would like to have the opinions of the most ripe experiences and the most matured judgments on the question. That question really is, whether gum bichromate is to be allowed to occupy its present position in photography or to be compelled to secede. Is it to be dubbed an unpleasant name, thrown out from photography and refused admittance to painting, a little more than the one and less than the other?

It seems to me that it should be boldly admitted that the old attempts to define and limit photography to something produced *wholly* by the action of light are quite unsuitable to the necessities of the times. The child has outgrown his garments, and wants a new suit. Photography, indeed, should be made to embrace everything the *genesis of which is in the camera*.

It might be argued in opposition to this suggestion that a photographic print, worked upon with paint almost out of recognition, would find a place in the ranks. Well, it would find its own level. A print which was plastered with paint would be taken for what it was worth, and we might go on our way undisturbed at its effect upon photography. The "survival of the fittest" would operate to eliminate what offended against taste and real art. It does not seem likely, for instance, that any enlargement of the bounds of photography would encourage the worst type of so-called "club portraits."

A confused medley of variously produced prints? There is no reason why a photographic exhibition should be that. It is quite true that the principle which directs the division of water colours from oil paintings at the Royal Academy does not apply here. Still, in effect, no one finds the separation of these two types of brushwork from one another inconvenient or objectionable. Why, then, should not all gum-bichromate prints be hung by themselves in one part of the exhibition room?

At any rate, it would be advisable to place the scope of what is, for convenience, called photography upon a larger footing, instead of narrowing it down to what the strict meaning of the word implies. It cannot be right that such gum-bichromate prints as we saw at the Salon, which are not the outcome of pure photography, and, in the abstract, are not *strictly* entitled to be admitted to an exhibition of pure photography, should be there simply on sufferance. It would not be right, nay, it would be madness, to discourage, or, worse, to cast forth any such fruit of invention, or product of imagination, merely as "anathema destined to destruction." Not by a perpetual running round and round do we progress, but by steadily marching onwards and outwards, fired with a spirit of true liberality, with the instinct of wise toleration, which has for its motto, "Live and Let Live."

HECTOR E. MURCHISON.

### ON THE REMOVAL OF SILVER STAINS FROM GELATINE NEGATIVES.

PERHAPS there is no more dreaded injury throughout the whole course of photographic procedure than that arising from the staining of valuable negatives by reason of having placed the same in contact with one or other of the silver printing papers during damp weather, or by the accidental or unseen attachment of a sheet of printing paper to a negative some portion of which is in a damp condition.

In such cases as where a spot of rain or water has accidentally fallen on the surface of a negative and printing paper has been placed in contact unknowingly, the mischief soon becomes apparent, and by soaking both the negative and the partially printed picture at once in a bath of clean cold water a very little coaxing will suffice to detach the adhering paper from the surface of the negative without injuring the same to any extent. There is, however, a far more insidious source of stains to which negatives are liable, and which arise even in the face of what many may term sufficient precautions being taken to guard against such injury. These stains do not put in an appearance during or for a considerable time after the negative has been in use for printing, and it is only when such negatives happen to be examined some time afterwards that the dreaded brown silver stains become visible. These silver stains have by many expert photographers been considered beyond the possibility of removal, or at least as capable of being removed without at the same time injuring the negative to such an extent as to practically ruin the same; and, judging from the repeated questions that appear in various of our photographic journals, it has come to be looked upon as an injury quite beyond the power of any one rectifying.

For several years I closely studied this matter and spent much time and pains in endeavouring to find a remedy for these stains. I need not trouble the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY with a detailed statement of the numerous experiments that I conducted from time to time; the main point lies, however, in the fact that such experiments have resulted in my succeeding in the attempt; and, as will be seen on perusal of the following lines, even in a surprisingly simple and easy manner.

When I first studied this matter I was forcibly impressed with the difference in appearance which those negatives presented that had been stained for a considerable length of time over those that had only recently contracted the stain. In the former case, such as where a negative has been stained and placed away for several months, this brown stain will in all probability advance to what I term a secondary stage of the trouble, that is the brown colour which first puts in an appearance will become not only more pronounced and get deeper set into the film, but the surface of the stain will assume a peculiar metallic or lustrous appearance quite absent in cases where the stain is of recent contracting.

Of the two kinds of stains the former proved during my experiments by far the more difficult to eradicate, and I soon found out that the treatment which sufficed to remove an ordinary silver stain, that is, in cases where the metallic or lustrous appearance was absent, was quite ineffectual to remove such stains when this additional evil was present, and after several attempts I saw clearly that this metallic appearance was only confined to the surface of the stain, and was in point of fact acting as a waterproof coating, resisting any reducing fluid or solution that was applied to the surface of such.

A little reasoning then induced me to try the effect of removing this metallic lustre by other than chemical means, and so I gave my attention to the application of some mechanical means whereby the thin coating could be removed by friction, and no sooner did I resort to this treatment than I at once became master of the situation and could remove the most pronounced stains with ease without injury to the negative.

Any one who has had experience of this trouble will readily understand that these stains put in an appearance more frequently when gelatine negatives have not been varnished, although a coating of varnish is not an absolute protection against such. Should such stains have to be treated in cases where negatives have been varnished, the first step is to remove the varnish by soaking the negative in strong methylated spirits until the varnish is quite removed. Such films will then be in a condition to be treated to the necessary manipulations which I am about to describe.

In the case of a negative which has contracted this injury the surfaces of which have a metallic appearance, the first step necessary before subjecting the film to the application of any reducing agent is to get rid of the metallic deposit by means of friction, and after several attempts I found I succeeded best by employing some extremely fine pumice powder. It will stand to reason that such powder must contain no lumps or particles that would be liable to cause injury to the surface of the negative or scratch the same to any extent. The sample of pumice powder which I have found most suitable is that used by process-block makers for polishing their zinc slabs, and called by some workers levigated silicate. This powder contains no lumps or coarse particles, and has proved in my hands invaluable for this purpose.

It stands to reason that, when it is applied to the surface of the negative at those parts where the stain is located, it should only be rubbed over the stains alone, and with a gentle touch working in a circular movement with the point of the finger. It will be seen that

only a slight friction is needed at this stage, for the aim is not to remove entirely the silver stain by its means, but merely to cause the metallic coating to disappear so as to permit of the action of the reducing solution which is afterwards to be applied.

The application of pumice powder in this work is, however, quite within the bounds of practicability, and any one can rub the surface of a stain without in any way injuring the negative.

When once it is seen that the metallic appearance has disappeared, the remaining treatment consists of the exercise of a little patience, no skill being required, for all that remains to accomplish is simply soaking the negative in the necessary solution until the stain has disappeared or at least so far reduced as to become of no practical detriment to the negative.

In cases where negatives have contracted these stains, and they are not of long standing, the application of rubbing is not required, and a few minutes' soaking or immersion in the reducing solution will cause their removal as if by magic.

On the other hand, there is a class of stains that may have been present in a negative for a long time, even years, and which, though being well stored, never appear with the metallic deposit on the surface, but have the stain deep down into the film, and negatives taken on thick film are more troublesome to deal with than thin ones, although as yet I have never met with a case beyond the possibility of yielding to the treatment I am describing. It is only a matter of time; stains of recent contracting may yield to the treatment in five or ten minutes' time, whilst those of long standing may require several hours before the stains will disappear.

In the course of my experiments in this matter I naturally reasoned in my own mind as to what these stains consisted of, and was driven to the conclusion that a stain which had not contracted a metallic lustre consisted more or less of chloride of silver, and so I proceeded, first of all, to produce a negative with the stains by placing in contact sensitive paper and a damp film. In three days I had a plentiful crop of the evil, and then I waited a few days longer, during which time I repeatedly watched the progress of the stains by means of a microscope, using a good quarter-inch objective.

The outcome of these experiments prompted me to try the power of our good old friend hypo as a reducing agent, and to my great satisfaction, after immersing the negative with the stains that I had purposely caused to appear, the stains disappeared, as by magic, in less than ten minutes.

Encouraged by the success of this experiment, I immediately looked out some negatives that had been stained for years, and also solicited several from my friends; in every instance the results were successful where no metallic coating of the stain was present. I then set myself to reason out the necessary treatment of negatives having this defect, and, by removing the same with friction as described, and eventually immersing the negatives in freshly mixed hypo, in the proportion of three parts of a saturated solution to one of water, I invariably succeeded in getting rid of the stains; but, as I have said, it takes a much longer time in the hypo to remove deep-seated stains than those of recent contracting. I feel sure that any readers of THE BRITISH JOURNAL OF PHOTOGRAPHY who carefully apply the treatment will find these dreaded visitors more easily got rid of than has hitherto been deemed possible; but it should be borne in mind that the sooner a negative is treated after it has contracted these stains the better, five or ten minutes in the hypo will then remove them.

A. T. NEWTON.

### ON THE MEANING OF THE PHRASE "EQUIVALENT" AS APPLIED TO LENSES.

IN 1840 the mathematician Gauss discovered that the position and magnification of the image formed when an object is situated on the common axis of any system of refracting surfaces, including lenses of any thickness, depend only on the positions of four fixed points on the axis. These points are the foci,  $F, F'$ , of beams parallel to the axis, incident on either end of the system of lenses, and  $H, H'$ , the two conjugate foci at which object and image are of the same dimensions, and both erect; in the case of any ordinary lens this object and image will be found to be formed by virtual pencils. The points,  $F, F'$ , are easily found by examining the position of a distant object; one of them, in fact, is the point on the ground glass of a camera at which a distant axial body is clearly focussed. The other points,  $H, H'$ , are inside the lens, but their distances from the foci can be found, not approximately, but absolutely, by a simple practical process, or it may be expressed mathematically in terms of the focal lengths of the various lenses and their distances apart.

The ordinary formula for connecting the positions of conjugate foci becomes simplified if their distances from  $F, F'$  respectively are measured: it is, if  $HF$  which is the same as  $H'F'$  is called  $f$ , and these distances respectively are called  $x, x'$ , simply  $xx' = f^2$ .

Before proving this, and another simple formula for the magnification, I shall first examine the positions of the four points in the case of a simple lens, regarded as very thin; next I shall show how the posi-

tion and magnitude of an image are obtained when these points are given in the more general case; and, lastly, I shall examine what the phrase "equivalent lens" may be taken to mean.

Fig 1

In the case of a thin lens (fig. 1), the foci need no definition, and the principal planes (i.e., the planes through the points of unit magnification and perpendicular to the axis) coincide with the lens, for clearly an object close up to the lens appears just as it is. Thus the points H, H' merge into one H; and if AHB be the lens, PQ, P'Q' object and image, we may ascertain the position of P from that of P' by considering where any two rays from P intersect after refraction, for clearly this will be the point to which all the rays from P converge. The two particular rays usually chosen are that through H, the centre of the lens, which is not refracted at all, and that parallel to the axis. But, for the present purpose, it is better to select the ray PA, parallel to the axis, and PB, that ray PB that passes through F. Let  $FQ = x$ ,  $F'Q' = x'$ ,  $HF = HF' = f$ , then the magnification is the ratio of P'Q' to PQ.

$$\text{Now } \frac{P'Q'}{PQ} = \frac{BH}{FQ} = \frac{HF}{FQ} = \frac{f}{x}$$

$$\text{and also } = \frac{P'Q'}{AH} = \frac{F'Q'}{HF'} = \frac{x'}{f}$$

by the properties of the pairs of similar triangles FPQ, FHB, and F'AH, F'P'Q'.

Hence we have

$$\text{Magnification} = \frac{f}{x} = \frac{x'}{f}$$

$$\text{and } xx' = f^2.$$

In any compound lens we can prove (but the mathematical work though elementary is long) that  $HF = HF'$ , and by analogy we shall call this length  $f$ . On referring to fig. 2, where the lenses are not inserted, it will be seen that the reasoning is identical in character. We know that, whatever the course of the rays between the planes through HH', a ray through A on the plane AH will emerge at A' on the plane A'H' where AA' is parallel to HH', for objects in the one principal plane have equal images in the other, by the definition above.

Fig 2

Also the particular ray from P, parallel to the axis, must, after refraction, pass through F'; hence PA emerges in the direction A'P'. What it does between A, A' depends on the internal constitution of the system of lenses, and not on H, H', F or F'. Again, the ray, PFB, must, after refraction, emerge in the direction of B'P'; hence P' is the focus conjugate to P. By the same reasoning as in the previous case we have—

$$\text{Magnification} = \frac{f}{x} = \frac{x'}{f},$$

$$\text{and } xx' = f^2.$$

It is clear that, if two lenses of the same focal length,  $f$ , one a single lens (fig. 1) and the other a combination (fig. 2) be taken, the images of equal objects (PQ), at equal distances ( $x$ ) from the front foci (F), will be of equal magnitudes (P'Q') in each case, but, on account of the interval, HH', in the second case, will be different distances (QQ') from the objects. Again since in any doublet HH' cannot coincide, no single lens can possibly be equivalent to a doublet in the sense of producing an image of any given object, identical in magnitude and position, with that produced by the doublet.

But it is easy to see where a single thin lens must be placed in order to produce the same image as the doublet for any particular position of the object, for, on joining PP' (fig. 2), its intersection with HH' will give the position of the necessary single lens, while its focus can be calculated from the conjugate foci, P, P'.

If we call HH',  $b$ , it can be shown, without much calculation, that the distance of this single thin lens from H' is  $\frac{bf}{f+b}$ , and its focal length

$f(1 + \frac{b}{x+x'+2f})$ . These results indicate very clearly that both the position and focus of the thin lens equivalent to a combination of lenses must vary with the position of the object. The extreme cases are when Q is very near or very far from F. Supposing the object to be moved from F outwards, the equivalent thin lens will be at H when Q is at F, i.e., when  $x=0$ , and move nearer and nearer H' as Q moves off to an infinite distance. Its focal length will be  $f$  when Q is either at F or at an indefinite distance, and departs from this value to the greatest extent when  $x$  is equal to  $f$ . In this case  $x'$  also =  $f$ , and the focal length is  $f + \frac{1}{2}b$ . It must be noted that in an ordinary doublet lens  $b$  is small and negative; so the equivalent thin lens has a minimum focal length in this case.

It will be observed that, when  $x=f=x'$ , the magnification is unity, as is well known, but the image is reversed, a very important distinction.

From the preceding results several important conclusions can be drawn and summarised thus:—

1. Two systems of lenses are strictly equivalent if for all positions of the object, and of the image formed by one, the other can be so placed as to give an image identical in position and magnitude.
2. For this to be the case it is necessary that the four cardinal points, F'H'HF, should be situated at exactly the same distances for the two systems of lenses.
3. Since these points only involve two quantities, namely, F'H', which is equal to HF, and H'H, and a doublet involves three quantities, namely, the focal lengths and separation between its elements, regarded as thin lenses, there must be some latitude in the choice of these three quantities.
4. Hence a symmetrical doublet, but only one, can be found exactly equivalent to a given system of lenses. It may be noted that this combination will be less separated than any equivalent doublet.
5. No thin lens is equivalent to a doublet in the strict sense; but, for any particular position and relative magnitude of object and image, a single lens can be found that can replace the doublet for this particular case only.
6. For distant objects (e.g., in landscape work) this thin lens is practically fixed in position and focal length, and may therefore be loosely called the equivalent thin lens. Its position is at H', and its focal length is  $f$ .
7. A single thick symmetrical lens equivalent to any combination can always be found.

For those who care for exact formulae, I have gathered a few here. Let there be a doublet consisting of two thin lenses, focal lengths,  $f_1, f_2$ ,

Fig 3

separated by an interval,  $a$ . Then, if LL' are these lenses (fig. 3), we shall find—

$$LF = \frac{f_1(f_2 - a)}{f_1 + f_2 - a}, \quad L'F' = \frac{f_2(f_1 - a)}{f_1 + f_2 - a},$$

$$LH = \frac{af_1}{f_1 + f_2 - a}, \quad L'H' = \frac{af_2}{f_1 + f_2 - a},$$

(whence H is to the left of H', and  $b$  must be reckoned negative, as remarked before, in fact,  $b = \frac{-a^2}{f_1 + f_2 - a}$ ),

$$\text{and } HF = HF' = \frac{f_1 f_2}{f_1 + f_2 - a} = f \text{ (say).}$$

If  $F_1, F_2, A$  are the corresponding quantities for any equivalent lens of the same kind, we have at once from the equality of  $f$  and  $b$  in each case:—

$$\frac{f_1 f_2}{f_1 + f_2 - a} = \frac{F_1 F_2}{F_1 + F_2 - A},$$

$$\frac{-a^2}{f_1 + f_2 - a} = \frac{-A^2}{F_1 + F_2 - A},$$

whence, in a simpler form,

$$\frac{f_1 f_2}{a^2} = \frac{F_1 F_2}{A^2},$$

$$\frac{f_1 + f_2 - a}{a^2} = \frac{F_1 + F_2 - A}{A^2}.$$

It is easier, however, to find HH'F'F' practically, and the result has the merit of being independent of any assumption as to the constituent lenses being thin. The formula could, of course, be corrected for this, but would be very lengthy. The practical method is as follows:—

Mount the combined lens under examination and find the focus for distant objects, first viewed from one end, then from the other; this

gives the positions of F and F'; next find the positions of any two conjugate foci, Q'Q'; then, measuring FQ (x) and F'Q' (x'), we have  $xx'$ ; but this is  $f^2$ , or  $FH^2$ , or  $F'H^2$ , so that the positions of all four cardinal points can be plotted on a diagram and kept for reference.

PROFESSOR J. E. A. STEGALL.

### VANISHING ENGLAND; AND A SUGGESTION.

IN a recent issue of THE BRITISH JOURNAL OF PHOTOGRAPHY attention was called to "vanishing London," and success heartily wished to the efforts of Sir Benjamin Stone and others in preserving photographic records of what, in the way of old streets, bridges, &c., must soon, in the effort at accommodating increasing traffic, become things of the past. With equal truth, and as of greater general interest, attention might be directed more broadly to vanishing England, and something of systematic effort made towards similarly forming photographic records of many interesting types of buildings gradually being evolved by the stress of bricker civilisation out of existence. There is hardly a corner in the British Isles that has not something distinctive and peculiar in such a direction. Such need not necessarily be artistic; possibly, indeed, in many cases it may prove matter for congratulation that they can be regarded as disappearing; still they are, from a variety of causes, interesting. The picture of a crofter's house, for instance, would prove a great aid in understanding his position and woes; one of an Irish shebeen of value in realising the difficulties of settling Irish questions by Anglo-Saxon methods; or, as introducing a desirable and pleasanter, if not essential, artistic touch, there is the "black and white" house of the north country, more particularly perhaps of Cheshire, and most so of that country's interesting heart, the city of Chester. The genuine "black and white" house will before long have gone; imitations there are continually being built, but, apart from evidently lacking the charm of age, they are but bastard productions, conditioned to a newer order of things not obtaining in the times of the original ancient builders. What of old inns again, churches, market halls, and a wealth of others too great for anything like individual mention and notice? There is something extremely pleasing and valuable in these old buildings, apart from all artistic consideration, in that they must be faithful reflections of the character and ideas of the builders and the times they lived in, and the associations, sometimes rising to the dignity of history, connected with them. Why a "black and white" exterior? Why overhanging stories, latticed windows, and diamond panes? Or, treating the combined units as forming streets and towns, why should the former be so irregular and twisted in their course, the latter so crushed-up in character? Was it a question of warding off and breaking up the force of cold winds, and keeping all within the necessary protection of the ancient wall, or what? Questions interesting in a remarkable degree to one looking beneath the immediate surface, but which will soon have to be studied without the actualities to refer to, as these are being rapidly cleared away. Ancient houses do not meet modern ideas of comfort and hygiene, inns become hotels, churches are "restored," and market halls are not only sadly in the way in main streets, but absurdly inadequate to the needs of present-day trading. Cobbled streets are too trying for modern traffic and modern nerves irritably intolerant of rattle and noise; corporate effort is ever persistently directed towards straightening out and broadening; overhanging stories shut off too much light, and picturesque courts and closes are swept off as insanitary. Here, surely, is the chance for photography as an ideal recording means.

Beyond typical buildings and their particular arrangements, many types of English workers are also quietly vanishing. The changes are so gradual that we are not conscious of them, and the individuals becoming extinct are such familiar ones that we hardly regard them as worth preserving. A little more time and progress, and our estimate of value and interest will rise, probably too late to gain characteristic pictures. Looking back a little, how glad would we not be to have pictures as reliable as photographs of the chairmen, linkboys, hackney coachmen, bagmen, beadles, town criers, watchmen, and so on, who figured in the social life of the early part of the century. Applying the conclusion to present-day types of workers, we should endeavour to gain fairest and fullest records of them. The whole of a town, for instance, will soon be lighted at the shifting of a switch in a central lighting station, and the familiar figure of the lamp-lighter moving briskly along, carrying his little lamp at the end of a long pole, leaving a cheerful trail of light in his wake, will have moved out of the workaday world altogether, taking the gas lamp with him. To us the picture of either, or both, would not at present be particularly attractive, but in a few years' time they will have become so, both as a reminder of past times and a something definite and tangible to measure progress by. In proof of which, let it be asked if we now would not be glad to have photographs of the old oil lamp and its lighter. But, if it be thought too early yet to start upon a record of such present-day worthies as lamp-lighters, cabmen, omnibus-drivers, farm labourers in smock frocks, kilied Highlanders, top-hatted Welshwomen, and a host of others more or less rapidly travelling onward on the vanishing track, there is plenty left. The many quaint observances and ceremonies, for instance, in various parts of the country—May-day processions, Jack-in-the-greens,

Guy Fawkes celebrations, hiring fairs, and so on—that, as liable to be snapped up at any moment, ought to be carefully recorded in photographs. To take one from the first-mentioned class, reference may be made to surely the brightest and most pleasing of them all, the observance of May Day at Knutsford in Cheshire. Here the old English custom is kept up to the full, and the procession escorting the May Queen to her crowning place at the Maypole on the heath, is charming in the extreme. On a sunny day, wending its way, headed by morrice dancers, through the quaint lower town, it is as true and lovely a splash of mediæval colour, a scrap of old English pageant, as can be well conceived of. It is well worth recording, in common with many others, for they cannot long stand the pressure of the keen utilitarian struggle of to-day, with its maximum of work and minimum of play.

Many of the foregoing have, of course, been photographed, mainly by amateurs, but the range of the finished work is local, and, like the local prophet, not as highly thought of as it should be in its own country. The illustrated paper and magazine, it is true, diffuse them more widely at times; but there is a world of difference between a photograph and the newspaper print reproduced from it. The financial side of a paper, too, must be held in first regard, and the consequent more paying appeal to the greatest number does not by any means make for artistic righteousness and interest on the higher planes.

As more to the latter purpose, the suggestion is offered that a society be formed, recruited as widely as possible, for the photographic preservation of what is slipping away. A vast number of amateur photographers, men of high intelligence, culture, and artistic tastes, must already have in their possession negatives of great value to this end, which they would be ready to lend for careful printing from. They would be as ready to become members of a society formed to gain similar prints of places, people, and events beyond the range of personal working. Could not this high array of photographic, and otherwise general, talent be formed into a united something in the way of society or association for the systematic taking and distribution of vanishing items of interest, such as those above referred to? The professional worker would be only too willingly welcomed if he cared to join in, for his presence would immensely strengthen matters. But, as he could not expect pay on the full professional scale for any work done, and his particular hobbies, like those of the rest of us, run probably in other directions than bread-and-cheese grooves, he could hardly be expected to find as much inducement to join as his amateur brother. Many artists, readers, and folk-lorists generally, outside the photographic ranks, would, doubtless, be also glad to have so many well-finished prints in return for a yearly subscription.

It would be premature, in such a crude first suggestion as this, to enter into any elaborate details of construction and administration, they could be readily drawn up at need upon a workable basis by a few experienced technical workers and business men. To pass the matter on a stage, however, it might be suggested that members pay a subscription into a central fund, to be spent, at the discretion of a small working committee, in selecting suitable existing negatives, arranging for the taking of particular objects determined upon, and the final printing and distribution of the finished results. The individual member would thus have a certain number of photographic pictures monthly, or three-monthly, in return for his subscription, graduated in number, if you will, according to the value of a subscription varying in amount. His own work would be paid for in money or kind, not, admittedly, to its full value, but the higher standards by which the pleasure of intelligent hobbies is measured are not money ones in the photographic, more than the general, world.

If so far successful, in this age of cheap production and specialised publications, a supplementing of pictures with descriptive letterpress, and articles bearing generally upon the subject, might in due course be entertained and ventured upon. In this way might easily be attained the general lifting and spread of knowledge of the particular subject, the glorification of the photographic means, and the preservation in many cases of objects of high value that, lacking a little aid, are oftentimes allowed to fall to ruin, or, lacking a little intelligent interest, unnecessarily "improved" away.

JOHN REES.

### PICTURESQUE BITS: WHERE TO FIND THEM.

I KNOW too much about exhibitions to put great faith in the value of them as standards held up to show the rank and file that here is true art, and, as for the medalled, to take it for granted that here is the ideal photography; but, however that may be, we see in exhibitions a reflex of what is being done, or attempted, in this art of ours all over the world. I have seen it stated somewhere that thousands of these high-art and poetic productions were made in the earlier years, and washed off the plates as unutterable and disgusting failures. That is true, no doubt, in a sense, for the bulk of the more advanced (in photographic years) of us were trained to consider the "perfectly sharp" as the ideal; sometimes we got atmosphere, and the result was then a marvel. I do not think, after all, that it was a bad school to be trained in, that of pure photography, chemical and literal. When, at length, a very few started on a newer tack, and produced and showed photographs distinctly diffused—I

need only instance those of Mr. Galloway, shown at the earlier of the Newcastle series of exhibitions—the effect produced had in it more of tolerance than admiration, and yet Mr. G.'s productions were undeniably good, and were pictures. Where the most of us made the mistake, and do still, was in taking too much on one plate, a print measuring 8×6 might have upon it the elements of half a dozen pictures, but the rule was detail and plenty of it, and the results usually were topographical.

It is not necessary here to trace the evolution of the more modern fuzzy production. I don't think Amidol junior was deliberately fooling when he took his new 30s. half-plate set into the fields in search of the picturesque; true, his lens was only a periscopic, and his plate was upside down; but, being a new hand, we cannot blame him for that. He was also unaware that a little daylight was oozing through the camera front (which accounted for the striking sunlight effect), but the result achieved exceeded all anticipations, was pronounced to be so perfect by the Amidol family, all of whom are addicted to poetry, and therefore of "those who see visions and dream dreams," the indefinitely weird mistiness, that marvellous effect of sunlight, proved beyond doubt the birth of the ideal photography. It is common history, of course, that our hero completely failed to reproduce quite the same effect in his after-wanderings, though the sunlight effect aforesaid long haunted him almost to lunacy. I think we must agree, all things considered, that there was no deliberate fooling, but the discovery of the fuzzy was a pure accident, and took some clever men several years of hard work to perfect.

If there is any special demand for the diffusive—and our exhibitions of recent years rather favour the idea that there is—I think readers will find, some of them that is, in this article a method of procedure which will yield, without undue exertion, something of the nature required.

After a few years of itinerant photography, a period, be it longer or shorter, in which the worker may have accumulated some hundreds of negatives, the picturesque may be in the bulk far from asserting itself, and to discover it we have to make search and selections; it will have to be sought for, and isolated from, its more commonplace surroundings—"Full many a flower is born to blush unseen," &c.

These lines of the immortal Gray rise naturally to our lips when we find, as we often may do, a gem of a picture hidden away in a mass of detail on some long-forgotten plate. When I invite the reader, therefore, to join in a search for the picturesque, it is not intended to go far afield, but to pick the "gems" out of the plates already exposed; the chances are that we have already in our plate boxes a very sufficient crop of "picturesque bits" which only needs harvesting—an operation which will pleasantly fill up many a long winter evening.

The idea has been to look through some boxes of negatives and select certain of them, or certain parts of them, for enlargement in the manner following:—

Many negatives are stored away and remain practically unused mainly because they are difficult printers, vaguely unsatisfactory in some point or other, not bad enough to quite discard, put away for further possible treatment perhaps. We must all have experiences of the kind, though by the way we need not confine ourselves to all the faulty or less perfect negatives. During one holiday season I exposed over a gross of films. Incidentally I may remark that with a roll-holder in proper working order, and with due care as regards light and exposure, there need not be five per cent. of failures; but roll-holders have not (as I can testify from painful and costly experience), always been faultless, and, of course, errors from other causes are always liable to creep in; however, the net results were not bad from that trip; amongst the remainder were some doubtful ones; you expose on a subject that takes the eye, and the result is not quite what you expect, it takes years of practical work with the hand camera to adequately comprehend its limitations, and one is being constantly tempted to expose where one's better and cooler judgment would pass the view by. Occasionally, as I have found, and as others may find, in aiming high you may be sure to hit something; thus it is that "some parts" of these doubtful films or plates may be, as the curate said of his "box" egg, *very good!* It is possible in this way to pick out many pleasing "bits," a tree, boat or sailing vessel, group or what not primarily only a part of what was aimed at; but now the "reason of the existence" of the plate. Lots of negatives may be failures in the bulk, but details may often be picked out which should save them from destruction; look through them and most likely we shall be able to find plenty of material to work upon. More particularly on account of its convenience, and under certain conditions, certainly the lantern will be the best medium for the enlarging operations; the subjects to be treated will be mostly on the small scale, the enlargement need not exceed twelve inches or so in height, and the subject can therefore be brought nicely within the circle of a four-inch condenser. The circular shape is in itself often available, while masks should be cut in a variety of shapes, fan, palette, and such other designs as may commend themselves.

Now, each operator may please himself as to mode of working; the plain bromide enlargement direct from the negative is, of course, the simplest method; here, however, we must suppose that a really good negative or "bit" is to be operated upon, and in such a case we may interpose a mask of any desired shape, and get our picture direct. This is not what I am designing at all; we want rather a method which shall call into use more of the personal element, and exercise all the skill and

artistic sense we may be capable of. There are advantages and possibilities in this direction, if we make larger negatives, which may be worked upon and improved, and from which prints can be produced in various ways and in a variety of colours (as in carbon), and which, moreover, may be designed to give any amount of diffusion, if that be a *sine-quâ-non*. Briefly put, I make enlarged paper negatives, which, after being worked up, improved, as far as possible, by retouching, are waxed and printed from. Paper negatives may be made as fine in detail and grain almost as dry plates; they are eminently suited for prints on smooth or rough bromide papers, carbon, or platinotype, or gum bichromate. Owing to the surface, they take before waxing a pencil mark easily, and cloud effects may be readily worked in by the exercise of some skill and patience, and scarcely one but can be improved to some extent.

Our lantern will require a little attention. Having been put away clean and empty, all we need do to it is to put in new wicks and fresh oil. The principal point about oil lanterns is *cleanliness*: fresh oil (of the best quality), with a small proportion of camphor added, and clean carefully trimmed wicks. For the purely enlarging work the main points are, to get rid of the flame spot or shadow, which may be done by coating one face of the condenser with fine matt varnish, or by inserting between the glasses forming that lens a disc of new and white mineral paper; and, secondly, to fit the front lens, which, in all the usual lanterns, will be achromatic, with one or two diaphragms or stops. The simplest way to do this is to cut a disc of black cardboard, make a central hole of three-quarters of an inch diameter, and place between the lenses; it may be held in place by a couple of folds of thin cardboard inserted one in front and one behind the disc; these folds of cardboard, if not too thick, will fold close up to the jacket or tube of lens. The definition of the picture will be improved by the use of the diaphragm, but, of course, the exposure must be increased *pro rata*.

The next thing is to provide a simple camera arrangement (having a focus screen and plate-holder at one end), into which to thrust the lens and project the enlarged image. A somewhat similar apparatus to that commonly used for making slides by reduction is most convenient, and is formed of framework with carriers at one end over which, during the operations, the focussing cloth is thrown. We get practically the same thing, and, what is of importance, a little more *weight*, by selecting a box or case about 2 feet long by 1½ broad and deep; fit in one end of this an aperture and flange to carry a 12×10 printing frame, or larger, and at the other end make a round hole, through which to put the lens. Now, if we remove the top and one side—that side, by the way, on which the operator will find it most convenient to work—we may insert a half-inch curtain rod at the vacant corners and throw a cloth over to cover the top and side, a neat arrangement is made which will serve all purposes. The printing frame is made to fit closely and is buttoned up; a focussing screen of finely ground glass should be made (using matt varnish) or bought, as enlargements intended for negatives should be finely focussed by transmitted as well as by reflected light. As the degree of enlargement may not greatly vary, the apparatus need not be over-bulky or inconvenient to handle; indeed, the whole of the arrangements need only occupy a small table. The use of a screened space is recommended, as every care should be used to secure images free from fog, more care, as a matter of fact, being necessary in the making of negatives than if we were doing plain bromide enlargements. In focussing also it is well to examine the image both by reflected light, as on a piece (12×10) of stiff white board put into the frame, as well as by looking at it through a square (12×10) of ground glass, also put into the frame for the purpose, in order to try to get as sharp a picture as possible; no doubt it will be pleasantly and sufficiently diffused by the time the operations are completed. In the event of a mask being used—and I find it always an advantage to have a clean, sharply defined edge—it should be inserted in the frame immediately in front of the sensitive surface. This completes, I think, the list of our mechanical requirements.

The manipulations being so much like the usual thing to which operators are accustomed, it will be necessary only to touch upon each detail in the order it is reached. We begin with the *transparency*. This, having marked out the "bit" to be enlarged, we make by contact, using an ordinary lantern plate. The exposure should be timed so that we get full detail and not too great density. We want a good enlarging colour, and *brown* is a good colour to aim at, as clean and perfect an image as possible, but fully soft. The picture will be, as a rule, printed out direct. In a few cases a vignette may be made of such subjects as lend themselves to such a method of work. We are guided mainly by what we wish the resulting print to be like, and try to make things easier for the printing stage. Any special gift we may possess in the way of selection of subject, balance, perspective, and form will be brought out in the process.

With regard to bromide papers, it is not a meaningless phrase to say that all are good, and, if for the present purpose I mention the products of the Elstree firm, it is because these remarks have been written after some full experience of their special adaptation, not only for negative making, but for the finished pictures.

With the special negative paper, a fully exposed negative image is got in from twenty to thirty seconds. The developer is strictly according to directions, viz., amidol; but it is well always to expose a trial strip of

paper, placed diagonally, to take in a fair sample of the lights and shades of the subject, and to develop this out fully and fix before proceeding to the actual enlargement. The operations are simple, but the following points are essential: plenty of room and light, a good supply of developer, water supply, dishes, and so on. The lantern has already been referred to. During development we may make use of a fair amount of canary yellow light, but naturally use all ordinary precautions to prevent undue exposure to stray and reflected rays of light, as from the lantern body.

The exposure will be correct if we can, within the limits of a few minutes, and without undue forcing, get full density; allow something for loss in the fixing bath, and also for the use of a final clearing bath; this is important, for the intensification of paper negatives or positives is not an operation to be taken on lightly. The developer is appended:—

Water .....	20 ounces,
Sulphite of soda .....	650 grains,
Bromide potass .....	10
Amidol .....	50

Mixed in the order named and used within a week. The amateur of limited surroundings, the "sentry-box amateur," may comfort himself with the assurance that the above solution is pre-eminently a safe one, that a trace of hypo, should any by chance get in, does not mean ruin to the print; but mind this, it must be only a trace. Neither is an acid bath necessary—the developed negative is plunged at once into the fixing bath. The procedure is as follows: Expose the paper dry; then, after exposure, remove to a dish of water to soften, and see that (handling only by one corner) the sensitive surface is free of air bells; now remove and drain for a few seconds, and place in the dish containing a sufficiency of developer; handle carefully, and turn over to avoid any collection of air bells; if correctly exposed, the image will begin to appear in a few seconds; when sufficiently developed, remove and place in the fixing bath (hypo, 4 ounces, water to 1 pint), moving about occasionally during ten minutes; the paper should be handled only by means of "clips" to avoid finger marks and stains. The image should not appear too quickly; on the other hand, "tardy development" will almost certainly prove fatal, because the negative is sure to be too hard and coarse for our purpose. The enlarged negative should, and will invariably, be better than the original—stronger perhaps, and yet soft enough to give capital prints; when dry, it will be ready for flattening out by placing between clean blotting-paper and under a weight, then retouching, making such improvements as we are able by means of a carbon pencil (special bromide retouching). It is surprising how skilful some amateurs become in work of this kind, putting in cloud and light effects in soft printing negatives.

Waxing the paper negative is not an absolute necessity, but it is better and a decided improvement. An easy way to do this is to provide a shallow tin tray, a little larger all round than the paper; place the paper negative (it must be quite dry) in this, and on the top of it a few pieces of clean paraffin wax. Now place the tray in front of a good clear fire, or in the oven, not too hot, and, when the wax is melted, the paper will be found very completely saturated, and may be lifted out and quickly drained before the fire. If now the waxed negative is placed between folds of white blotting-paper of the non-stuffy variety, and a hot iron passed over, the result will be very satisfactory. The negative is ready for printing from at once.

An easy way of flattening the negatives, whether for waxing or not, is to—after washing and drying—once more wet and squeegee face down to a vulcanite or ferrotype support.

I have referred to the Wellington negative paper so far because certain results have been achieved with it. The rolls of six-and-a-half-inch width are very suitable, negatives of  $6\frac{1}{2} \times 12$  and so on make a capital size and shape to work with; or, of course, one can use the cut pieces  $10 \times 8$  or  $12 \times 10$ . The remainder of the operations, if bromide prints are intended, are so similar to what has gone before, except, of course, the exposure by contact, that further reference to them is superfluous, while other printing processes, as carbon and gum bichromate, for which such negatives are specially adapted, are beyond the scope of this present article.

J. PIKE.

### SILHOUETTE PHOTOGRAPHS.

THERE is considerable value in a well-made portrait à la silhouette, say<sup>6</sup> an American contemporary, provided its profile limitations are applied to the preservation of a good type. Poise, proportion and individuality of features, characteristic carriage and striking habits in dress may be most effectively presented, and, before the days of Daguerre, silhouettes were very largely in demand and very highly prized.

As an artistic adaptation of the silhouette may be mentioned a recent portrait of a great musician, a combination showing the entire figure of the pianist in silhouette, while the piano at which he is seated, and a few lines indicating the character of the surroundings, are sketched in artistically, thus demonstrating a possibility in the use of silhouette drawing that is decidedly attractive.

The production of silhouette pictures is as old as mythology. The first silhouette was the charcoal outline of his shadow on the fire-lit wall,

made by a Greek maiden when her lover left for the wars. The name silhouette is said to have been originally a term of contempt, signifying penuriousness, and applied to shadow pictures as the "poor relation" of art and photography. Some of the old silhouette workers were wonderfully clever, and their work far from a reproach.

The scissors are, however, now superseded by the camera, and even intricate silhouettes may be produced without a great deal of difficulty.

There are worse things than a case full of silhouettes with which to attract the attention of patrons. The silhouette, devoid of accessory, makes a very direct and forceful appeal, and a good silhouette is often an unmistakable and characteristic likeness.

For taking silhouette pictures an ordinary room is, perhaps, preferable to a studio, in that all the light may come from behind the sitter. Choose, if possible, a north light. In front of the window hang a thin white cloth, to soften the light. This should be hung some little distance from the window frame, so that no trace of shadow may fall upon it. It must be free from creases—fastened to rods top and bottom—to give an absolute flat light. In front of this screen place the sitter. All the light is thus arranged behind the object, supposing a room with a single window to have been chosen. There will be no difficulty as to how the picture will look, for the image on the ground glass will be a sharp and distinct silhouette. A thickly coated and very slow plate should be used, with development for absolute density, and clear glass, and the negative should afterwards be intensified. The best developer is pyro soda, with a fair amount of sulphite. If needful, retouching is easily done with a fine brush dipped in opaque pigment.

For printing, a matt surface paper is desirable. The silhouettes can, if preferred, be cut out and pasted on to a card, in exact imitation of the old style, or they may be printed on a sheet of paper giving ample margin. Generally, they look best unmounted, or mounted on a card, to give stiffness without a margin of card being shown.

Children are often very well rendered by silhouette, and a child may easily be taken full length. For this a table should be placed before the window, at such a height that the top cuts the light. On this the child may be posed in profile standing or sitting. With a little thought and experimenting, many delightful poses may be evolved. The camera, in the case of a full-length, should be placed with the lens at exactly the same height as the top of the table. If the lens were higher, the feet would, of course, be lost in the black mass of the table and the effect would be destroyed. Before printing, a strip of paper may be pasted across the table, reducing the ground to a narrow strip.

### BETHELL'S DARK SLIDE.

ACCORDING to Mr. Bethell's description of his invention, the plate-holder for a double dark slide is made by fixing on each side of a piece of cardboard, or other suitable material, A, narrow slips of cardboard, B, B b, parallel to each other, about the same thickness as an ordinary photographic dry plate, leaving sufficient space between B and B b, on each side of A, to accommodate the dry plates.

At right angles and across one end of B, B b a piece of cardboard, C, of the same substance as B, B b, is fixed on each side of A.

"Over B, B b, and C, I place a piece of cardboard or other suitable material, D, out of which a slightly smaller aperture has been cut than the space formed by B, B b, and C when in position. A thumb-hole is

provided in D, to facilitate the removal of the plate; this arrangement, when the several parts are suitably secured, forms a rabbet or groove, E and E', on each side of A, into which the dry plate may slide and be held firmly. The top of the plate-holder is covered with a suitable fabric to exclude the light when the plate-holder is in the sheath, F.

The sheath, F, consists of a case made preferably of cardboard, covered with a suitable material, with an aperture cut from each of its sides to correspond with the aperture in the plate-holder. The bottom of the sheath is closed, preferably with a piece of wood the full width of the

plate-holder and the required depth, with a rabbet on each side, leaving a space in the centre sufficient to engage the two dry plates and cardboard, A, of the plate-holder; this arrangement provides for the shutter, G, to go below the bottom edge of the aperture of the sheath and effectually excludes light when the shutter is closed.

The shutters, G, fit between the two outer surfaces of the plate-holder and the inside of the sheath, so that, when the plate-holder, with a shutter on each side, is inserted in a sheath, two consecutive exposures may be made by first drawing up the required shutter, then replacing it, withdrawing the whole of the dark slide, turning it round, and repeating the operation.

The shutters, G, may be made of either metal or cardboard, or a combination of metal and cardboard or other suitable material. They may be of one rectangular piece of material, or, if cardboard is used, it may be creased at H in such a manner and position that, when drawn up at the time of making the exposure, the upper portion of G may be turned down at right angles with the lower portion, G, G'.

The upper and lower portion of shutters, G and G', may be suitably covered with metal, leaving the creasing in the cardboard uncovered, allowing the shutter to be turned down as described above.

The shutters, G, may also consist of a piece of cardboard creased at H, with additional pieces of cardboard or metal suitably attached to the upper and lower portion, the upper portion being so attached that, when the shutter is drawn up and turned down at right angles with the lower portion, the portion, J, may project over the top portion of the dark slide, and, if depressed when at right angles, may form a protection against light entering and spoiling the plate during a prolonged exposure."

#### HAAS' METHOD OF GRAINING PHOTOGRAPHIC SCREENS.

HERETOFORE, says Herr Haas, grained glass photographic screens have been made either by engraving in regular lines or by etching the plates, previously dusted over with asphalt powder, with the vapour of hydrofluoric acid.

Screens thus etched present an irregular grain, which, for most photographic purposes, is preferable to that of the ruled screens; but it has only been possible hitherto to produce etched plates of a very limited size, say  $7\frac{1}{2} \times 7\frac{1}{2}$  cm., and it was not possible to obtain such sharpness of etching as to render the screens fully equal to the ruled or geometrically grained screens.

Now, according to the present process, screens may be made of any size desired and with all requisite sharpness. This result is obtained by a special method of dusting, whereby a uniform distribution of the

asphalt dust is effected over the whole surface of the plate, and by special expedients in the etching operation.

The dusting operation is effected in such a manner that only the finest particles of dust are allowed to settle upon the glass plate. Within a closed chamber a powder, composed of a mixture of asphalt and "dragon's blood," is agitated and thrown up into the condition of a whirling cloud of dust which ascends through a vertical passage connected at top with the upper part of a dusting-on chamber, so that only the very lightest particles pass into this second chamber, wherein the glass plate to be grained is supported beneath a fine-meshed sieve upon a rotating table. The plate having been so dusted on, the dust is caused to adhere by being melted on in the usual manner.

The drawbacks of the etching operation as hitherto practised are considerably counteracted by uniformly heating the plate whilst the latter is exposed to the vapours of hydrofluoric acid, which will thus be prevented from condensing upon the plate, the arrangement for heating the plate being such that the vapours only pass over, and not under, the plate. The result is to produce a comparatively weak and accurately distributed action of the hydrofluoric acid upon the uncovered portions of the glass plate, violent impact of the vapours upon the plate being entirely obviated, whilst condensation of liquid acid upon the plate, and the consequent eating away of the glass under the dust particles, is prevented by the heating of the plates, and by the admixture with the asphalt of "dragon's blood" or of a similar resin.

The process is carried out in practice in the following manner:—

Referring to fig. 1, A is the dusting-on chamber, which communicates by means of the vertical channel, B, with the dust-stirring-up chamber, C. Within the chamber, A, the glass plate is supported on a rotary table, D, mounted on a vertical axle, E, adapted to be rotated by means of clock-work, F, a sieve, G, above the plate being mounted on, and rotating as one with table, D. The mixture of finely powdered asphalt and "dragon's blood" is introduced into the stirring-up chamber, C, wherein leather pallets, E, and brushes, F, carried by revolving arms, G, mounted on a horizontal shaft driven exteriorly by a belt, stir the dust up into a whirling cloud and project it upwards, so that only the very finest particles pass up through the channel, B, into the chamber, A, where they pass through the sieve, G, and settle upon the plate carried on the table, D.

The plate, after being thus treated, is heated in any suitable manner so as to produce adhesion of the dust by melting it on the plate, and the back of the plate is coated with a suitable varnish to protect it from the action of the hydrofluoric acid. The plate thus prepared is placed in the apparatus shown in section in fig. 2, wherein F is the vessel from which gaseous hydrofluoric acid is generated by the action of the flame, F', and rises through an inclined passage, G, at the upper part of which the glass plate, Z, to be etched is placed, the plate being arranged in any suitable manner (for example, it may be simply laid upon its back) on the lower side of the channel, G, so that the hydrofluoric acid gas must pass between its upper face and the wall, G, of the passage on its way to the uptake, H.

Below the support on which the glass plate, Z, is laid there is a second chamber, heated by a flame, H, from which the gases are caused to impinge upon the back or under side of the plate support, so as to heat the plate, Z, sufficiently to prevent condensation of the hydrofluoric acid vapours upon it.

#### A STRUT FOR PHOTOGRAPHIC FRAMES.

MESSRS. WALLS & BOYNETT carry out their idea in the following manner: The strut or support works on a pivot, thereby allowing the frame, easel, and the like to be placed in any position without detaching the said strut or support.

Fig. 1 shows the strut or support, which revolves on the pivot as shown by letter A.

Fig. 2 is a sectional part, showing the pivot passing through the disc, as shown by letter a. That part which revolves on pivot a is shown by letter b, the disk being a fixture.

Fig. 3 shows a side view of the strut or support when it is attached to the photographic frame.

## News and Notes.

**PHOTOGRAPHIC CLUB.**—April 12. Trade Night. New Apparatus, Novelties, &c.

**BRADFORD PHOTOGRAPHIC SOCIETY.**—The Annual Dinner took place on Monday, March 27, when about forty members and friends assembled. The President (Mr. Percy Lund) occupied the chair, and among the visitors were Mr. Godfrey Bingley (President of the Leeds Photographic Society) and Mr. Thomas Heaps (President of the Keighley Photographic Society). The most interesting toasts were those of the Bradford Photographic Society and the Yorkshire Photographic Union, the former being proposed by Mr. Godfrey Bingley, and responded to by Mr. Percy Lund, while the latter had as proposer Mr. George Thistlethwaite, and responder Mr. E. Clough. After the toasts there was a varied programme of music and recitations, to which the following ladies and gentlemen contributed: Miss Lily Ellison and Miss E. Ellis, Messrs. Alex. Keighley, Frank Robinson, Kershaw, and C. W. Maw. Two important presentations were made. Mr. John Snowden, who had recently retired from the Secretaryship of the Society, having occupied that position since its inception five years ago, received a handsome case of cutlery from the members as an appreciation of his services. In making the presentation, the President remarked that Mr. Snowden had earned the good feeling of his fellow-members, and had worked hard for the success of the Society in the early days, when its affairs did not run quite so smoothly as at the present time. Mr. E. Clough (Secretary of the Yorkshire Photographic Exhibition) was the recipient of an elegant épergne from the Committee of that Organization, in acknowledgment of his arduous labours in connexion with the recent successful Exhibition. Mr. Alex. Keighley (Chairman of the Exhibition Committee) made the presentation.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
10.....	Bradford Photo. Society .....	An Easy Method of Microscopic Photography. J. Leadbeater.
10.....	Camera Club .....	The Pyrenees. Herbert Spender, M.A.
10.....	Putney.....	Trimming and Mounting Photographs. Rowland C. Whiting.
10.....	Richmond .....	Lantern-slide Competition.
10.....	Southport .....	Platino-type Printing. George Cross.
11.....	Hackney .....	Still-life Photography. J. Carpenter.
41.....	Royal Photographic Society .....	The Correct Exposures to be given to Photographs of the Corona. E. W. Maunder.
12.....	Brentford .....	Declaration of Result of Exhibition and Arrangement of Summer Programme.
12.....	Croydon Camera Club .....	Lighting and Exposure. Francis T. Beeson, F.R.P.S.
12.....	Leeds Camera Club.....	Lantern and Slides. J. W. Garbutt.
12.....	Photographic Club .....	New Apparatus, Novelties, &c.
13.....	Camera Club.....	My Adventures with the Pigmies and Cannibals in Central Africa. Alfred Lloyd.
13.....	London and Provincial .....	Modern Hand Cameras.
13.....	Oldham .....	Exhibition of Members' Transparencies.
13.....	Woolwich Photo. Society .....	Portraiture. Harold Baker.
14.....	Croydon Microscopical .....	Conversational Meeting.
14.....	Leigh .....	Competition: Frauded Exhibition Picture.
14.....	West London.....	Bicycle and Camera. L. Selby.

### ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 23,—Technical Meeting.—Mr. T. Bolar, F.I.C., F.C.S., in the chair.

#### OZOTYPE WITH CARBON TISSUE.

Mr. THOMAS MANLY read a paper upon the subject of his new printing process, "Ozotype with Carbon Tissue," a method of photographic pigment printing without actinometer, transfer, or safe-edge, details of which were published in the last issue of THE BRITISH JOURNAL OF PHOTOGRAPHY (p. 198). The action of light upon chromic acid being thus expressed,  $\text{Cr}_2\text{O}_3 + \text{light} = \text{Cr}_2\text{O}_3 + \text{O}_2$ , he expressed the belief that in the ordinary carbon process the nascent or newly liberated oxygen combined with and changed the nature of the gelatine, but in ozotype it was made to do work in another way. Paper was coated with a solution of a bichromate salt and a manganous salt, and by the action of light the eliminated oxygen entered and decomposed the molecule of the manganous salt, producing an image in the sesquioxide or manganic oxide, the active oxygen being thus locked up for future use, while at the same time the image was visible and insoluble, so that the unchanged salts could be readily removed by washing. Only the acid light-sensitive compounds of chromium could be used, for decomposition immediately followed the addition of the neutral chromates to a manganous salt. The image at this stage was light brown in colour, and the next question for consideration was how to get the manganic oxide constituting the image to take up the pigmented gelatine of carbon tissue. For this purpose the phenol-derived photographic developers were useful, and small quantities of such substances added to about one-half per cent. solution of acetic acid made a bath in which the carbon tissue could be immersed, and which rendered it possible to produce a picture possessing all the half-tones and details of the negative. For well-printed proofs from good negatives the following formula was recommended:—

Water .....	1000 c. c.
Glacial acetic acid.....	2 to 5 "
Hydroquinone.....	$\frac{1}{2}$ gramme to 2 grammes.

A variety of effects could be obtained by modifying the quantities of the ingredients, the addition of acetic acid in very small quantities producing contrast, and increase of hydroquinone giving soft effects. The method of procedure was as follows: Print until the details in the high lights are visible, the sensitive paper being of about the same rapidity as platinotype paper; wash out the unchanged salts and dry; immerse the carbon tissue (unsensitized) for one minute in the acetic solution, the temperature of which should not be less than 65° and not higher than 75° F.; then place the print in the same solution, bring it into contact with the gelatine surface of the carbon tissue, remove them together, squeeze, and dry. When dry, the print and the adherent tissue are placed in cold water for not more than half an hour, and it is then ready for development in water at a temperature of about 102° F., thus dissolving those portions of the pigmented gelatine which have not been rendered insoluble by the action of the oxide constituting the original image. Mr. Manly demonstrated the various stages of the process with much success, and exhibited a large number of prints illustrating the results obtained with different tissues and the appearance of the unpigmented image.

Mr. BURTON said he had made some experiments with the process, and, although some further investigation was desirable, the results he obtained were of a satisfactory nature.

The Rev. F. C. LAMBERT said he had that day successfully developed some prints sent to him by Mr. Manly in July last. He asked whether phenol developers other than hydroquinone had been tried.

Mr. MANLY replied that pyro-catechin answered very well, but pyrogallol caused a stain; metol was good, but he did not recommend the amido developers. Convenient proportions for the sensitizing solutions were two parts of manganous nitrate or sulphate to one part of bichromate of potassium.

Mr. PAUL MARTIN alluded to the greasy appearance of the shadows in most carbon prints, due, to a great extent, to the excessive thickness of the tissue, and he asked whether a tissue less strong in gelatine would work equally well for ozotype printing?

Mr. MANLY said it would answer very well.

Colonel WATERHOUSE remarked that in hot climates, where carbon tissue rapidly became insoluble, Mr. Manly's process would probably be found very useful.

#### COMING EVENTS.

April 11, Ordinary Meeting. "The Correct Exposures to be given to Photographs of the Corona," by Mr. E. W. Maunder. April 18, Photo-mechanical Meeting. Exhibition of Apparatus.

### PHOTOGRAPHIC CLUB.

MARCH 29.—Mr. Frank Haes in the chair.

Mr. A. Mackie passed round a bottle of pyro solution made up in 1888, and tested in 1893 and rebottled. It was quite colourless, and at the last test worked very well.

Mr. F. A. Bridge showed a print in which he had striven to give the effect of a narrow lane lighted up by a great fire. The print was made without faking and subsequently stained, and the results certainly presented the appearance it was intended to give.

Mr. Clark showed some illustrations of what might be done by means of the half-tone process in advertising. He also showed a piece of a new alloy for photo-lithographing. The image transferred to it was as sharp as it would be upon a copper plate, and the alloy had all the advantage of a lithographer's stone as far as absorbed property was concerned, while for storage purposes it stood far ahead. Aluminium played the principal part in the alloy. The plate was printed from the negative with bichromate and albumen, and developed with a coating of printing ink and washing in water.

Mr. H. VIVIAN HYDE, F.R.P.S., gave his promised display of slides of

#### LOWESTOFT AND NEIGHBOURHOOD,

accompanied by a running commentary or chat upon the features of interest as they appeared. There was a pleasing variety of subjects, from the fishing smacks and quays, the markets, and harbour scenes, back through quiet lanes and meadows to the country of the Broad behind. The groups of fisherfolk in the first, and the picturesque yachts and wharries on the endless expanse of the rush-fringed Broad were charming examples of their kind, and the whole exhibition elicited the highly commendable remark that they reminded one very forcibly of the Club lantern-slide displays of olden times.

A hearty vote of thanks was passed to Mr. Hyde for his exhibition.

#### Newcastle-on-Tyne and Northern Counties Photographic Society.—

##### BINOULAR PHOTOGRAPHY.

At the last meeting of the Society Mr. J. HEDLEY ROBINSON, assisted by the Rev. Mr. OGDEN, demonstrated this subject in a very novel manner. All the diagrams illustrating the transposition of the prints before mounting were shown on the screen by means of a triple lantern, by which method Mr. Robinson was able to superimpose one diagram upon another, and thus explain the proper mounting of the prints. The lecturer also exhibited a very ingenious trimming board of his own invention, which so simplified the cutting of the prints as to render this part of the operation almost automatic. A small cutting board has a strip of brass fixed along its bottom edge in such a way as to allow the print to be slipped underneath, the print is adjusted so that the cutting edge of the brass bisects the same object in the foreground of both prints, two screws then clamp it down, the trimming shape is then adjusted on the left-hand print so as to include the exact picture desired, which is then trimmed with the exception of the foreground. The shape is then placed on the right-hand print, so as to include a little less on the left-hand side than was shown on the corresponding side of the other print. The right-hand print is now trimmed, and the knife finally run along the brass strip.

#### FORTHCOMING EXHIBITIONS.

1899.

April 7-May 13 ..... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

„ 12, 13 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 91, Cobourg-street, Plymouth.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

#### AN EASTER EGG—VULCANISED CAOUTCHOUC.

To the Editors.

GENTLEMEN,—Has any one found the following dodge before?

In hand-camera work the necessity of suddenly seizing a moment for the exposure, while still maintaining the steadiness of the camera, makes it extremely difficult to avoid a jerk.

Well, pop the ball of your pneumatic release between your teeth, and you will find the difficulty surmounted, especially when (as in a crowd) you have to hold the camera above your head or against your forehead. It is a fact that the jaw can be moved with less reaction ("rick") in adjoining parts than any part of the body except the eye, and we are in the constant habit from birth of moving the jaw without imparting the slightest motion to the rest of the cranial bones. True, this is a method of exposure of oneself to the derisive delight of the urchins ecstatic with their discovery of the newest and latest sort of donkey, but that does not influence the plate.—I am, yours, &c.,

HYPOCAMERITE.

#### THE FUTURE OF PHOTOGRAPHIC ASSISTANTS.

To the Editors.

GENTLEMEN,—May I call the attention of "F. S." and other photographic assistants to an article in the 1899 BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, p. 787, by Mr. Arthur Field, where a full description is

given of a trade union open to receive any photographic assistant. There is thus no need for "F. S." to wait one moment before setting to work to bring about the reforms he desires. I had thought these facts were known to every photographer, but apparently there are some so little interested in their professional position as to be ignorant of events of the most vital importance. Assume the same lack of interest in the operations of the dark room and the printing room, and we have a possible explanation of the surplus of incompetent assistants. My own experience is that the assistant who keeps himself well informed and up to date is not usually amongst the unemployed. No trade union is a cure for apathy, and can only be really effective when some eighty per cent. of the trade are enrolled. Given such a pitch of organization and all the moral qualities it implies, and we may then use it as a weapon of defence against the attacks of modern capitalism. The whole secret of the matter is thus to replace apathy and indifference by a lively and common interest through organization, and I trust that "F. S." will throw all his energies into this work.

The union above referred to deals with all the matters which press hardly on the photographic assistant; it gives legal advice, takes legal action on behalf of members, and last year 60% was recovered from employers by such action. No operator need be afraid of losing caste by becoming a member, for it is thoroughly "respectable." Secretaries and members even go so far as to appear at times in that black, shiny headgear, in the form of a cylinder, popularly known as the "top hat."—I am, yours, &c.,

JOHN A. RANDALL.

To the Editors.

GENTLEMEN,—Feeling the importance of the subject *re* assistants and their grievances, I beg leave to intrude again on your valuable space. I venture to think the real cause of the troubles to lie in the fact, that a photographer cannot tell what he is getting until he has engaged his assistant. "Specimens and photograph of self," which we so often see in THE BRITISH JOURNAL OF PHOTOGRAPHY, is inserted for the purpose of getting some idea of what the prospective assistant will be.

A week's trial, as suggested by one correspondent, would be almost impossible in a great many cases, but how much better if there were some means of knowing just what an assistant was capable of. This, however, cannot be arranged unless an influential move be made for the purpose. The granting of certificates by local institutes would be awkward in many places; and it occurs to me that there should be an institution probably where work could be sent in for examination, and where not only an opinion is passed upon the work, but a certificate granted. Now, just as the chemist qualifies for his certificate or diploma, so I think a practical examination should be open to the photographic assistant.

Suppose a department in such an institute to keep a supply of negatives which could be sent on to a "printer," let us say, who wishes to pass in carbon (single and double transfer), platinotype, P.O.P. (gelatine), albumen, collodio-chloride, or bromide contact work, which he must print and finish and return; then, if his work merits such distinction, let the institute book him as a "first-class printer." He would also hold the society's certificate as such. The same with retouching. These specimen prints could be kept by the society, and photographers coming to London (as many do) could easily see such prints if they cared to. Here, however, is a difficulty in dealing with posing and lighting. Such operators would have to come up to pass. When an assistant had not the means of making enlargements, he would have the advantage of doing so at such a place, and it would be a very simple matter to judge of a novice at the game.

A man under such circumstances, I fancy, would not have to stand long waiting for an engagement, and neither need there be any need for a good house to get hold of an unqualified man. Trusting to see something done before long to make things more equitable than at present,—I am, yours, &c.,

F. G. WILLIATT.

101A, Fulham Palace-road, Hammersmith, W.

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

W. G. Honey, 102, Patrick-street, Cork.—Two photographs of eight St. Bernard puppies.

A. JOHNSTON.—We believe the camera named fulfils all your requirements.

**CARBON PRINTING.**—C. BIGWOOD. You cannot have a better manual than the one you have. The sensitising of the tissue is, in practice, not the troublesome operation you seem to imagine; but, as a beginner, we should advise you to purchase it, at least at first, ready-sensitised. It is supplied in that state by Messrs. Elliot & Son, and by the Autotype Company. By so doing you will ensure having it in the proper condition for work.

**STUDIO.**—Z. W. If the Surveyor to the District Council has condemned the plans for the studio, we should advise you to get them modified to suit his requirements, for you may fairly assume that, as they are, the Council will not pass them. Your reading of the Building Act may be correct, and the law may be on your side, but, if you work in opposition to the Council, it will cost you a deal of trouble and expense, even if you succeed. It will also entail a considerable loss of time in getting the studio into use.

**PROPOSED AGREEMENT.**—NEMO. The draft copy of the agreement sent is similar in terms to several we have had sent us recently. It is all on one side, and that on the side of the employer. You say that you and your work have been well known in the town for several years, and, if you sign this one year's agreement, at the end of it you will not be able to practise photography in the town, nor even in the county, for three years afterwards. You should seriously consider whether it is worth your while to make so great a sacrifice on a year's agreement.

**STUDIO BUILDING.**—R. J. SCOTT says: "I am having a studio built from north-west to south-east, and should feel obliged if you would tell me which is likely to be the best end to place sitters? I ask your kind advice, as I want to be prepared to build dark room at the most convenient corner."—In reply: It is not stated whether the studio is to be lighted from both sides or one only. If the latter, it had better be arranged so as to place the sitters at either end. The dark room can then be placed on the dark side, midway between the two ends, that is, supposing the studio will be wide enough to contain it.

**CHLORIDE OF GOLD SOLUTION.**—J. WILLIS says: "I made up a stock solution of chloride of gold—one tube in two ounces of water—for sulphocyanide toning. After it had stood a day, there was a reddish metallic deposit at the bottom of the bottle. When some of the solution was added, in the proper proportion, to the sulphocyanide solution, I could get no toning action at all, even after two hours. I have made a second solution of gold, but with similar result. Why?"—Evidently the solution was made in a dirty vessel, or the water used was impure, and thus the gold became precipitated.

**THE NATIONAL GALLERY PICTURES.**—S. R. G.—We think you are misinformed. Amateurs are not allowed to photograph the pictures in the National Gallery, neither is there a photographic studio there in which the work could be done. Those professionals who have obtained permission to copy them have had to do the work in the different rooms in which the pictures are. A foreign firm, many years ago, had permission to put up a temporary studio outside the building in which to copy some of the works, but such a thing has not been allowed since, and possibly never will be again, so great was the indignation expressed at the time.

**GREEN PRINTING.**—T. AGER says: "Will you advise me how to proceed under the following circumstances: I want to produce some bright green prints, but cannot succeed after numberless trials, as they are all badly stained. 1. Can these prints be produced without this yellow tint in the high lights? 2. Can this yellow tint be removed by after-treatment? I presume it consists of chromate or lead. I find a very weak bath of sulphuric or hydrochloric acid 1 minim per ounce will remove the yellow, but very unequally, and a prolonged time or a stronger bath quickly converts it into an ordinary blue print. The specimen I enclose was produced as follows: Matt P.O.P. printed deeply and washed for half an hour under a spray producer; fixed for half an hour in strong hypo (twenty-five per cent. solution); washed for four hours; bleached by ferricyanide of lead; washed for half an hour; immersed in bath of neutral chromate of potassium; washed for half an hour; developed in bath of perchloride of iron; soaked in several changes of weak acetic acid; washed for half an hour."—Possibly some reader who has had experience with this method of producing green prints will give our correspondent the desired information.

**MOUNTING PRINTS WITHOUT COCKLING.**—R. B. HUGHES says: "I wish to put some prints in an album without cockling. An answer of yours to a correspondent some time ago scared me into giving up rubber solution, and I cannot manage mountaint given on p. 1061 of the ALMANAC. It 'jellifies' too quickly (my fault, no doubt). I obtained some white shellac from Chapman, Manchester, but it was wholly insoluble in boiling spirit. Can you kindly tell me, in your Answers to Correspondents, whether your remark about the resinising of rubber solution applies to its condition before use so as to prevent adherence, or to a change taking place afterwards, causing the print to loosen after having once apparently stuck firmly? Shortly, if the rubber causes firm adherence once, will it remain so for I have prints mounted since a long time without showing any signs of coming off; but one does not like the idea of a possible peeling off of prints in the future in an album intended for presentation."—In place of the No. 1 gelatine, try the No. 2 Autotype of the same makers, using three ounces instead of four, as given in the formula. If the shellac will not dissolve in alcohol, it shows that it is not a good sample, probably through long keeping. Indiarubber is a very uncertain mountaint; at times the prints will remain firmly adherent for years, at others they will come off in a few months. The reason for this difference is not easily accounted for.

**STUDIO BUILDING.**—A. V. says: "I shall feel obliged if you will kindly give me your advice on the following: I have the offer of proposed studio 25 feet in length, and, before accepting, would like to know if 25 feet would be considered sufficient, or ought it to be longer in order to carry on the best work? Are there any of the leading studios no longer than 25 feet? I should prefer a studio not less than 30 feet, but in this case it is impossible. Width is ample from 15 to 18 feet; it is in the length I am doubtful."—Twenty-five feet is a rather inconvenient length for professional work. Still there are many studios no longer, in which excellent work is produced. We should not advise you to discard the offer if the situation is good.

**FORMULA FOR RETOUCHING MEDIUM WANTED.**—NEMO says: "Will you kindly favour me with the following: A good formula for a reliable retouching medium, also a formula for toning with sodium formate. My experiments up to the present with the latter have been very varied—good, bad, and indifferent. Also will the bath keep, or does it have to be made up fresh?"—The formula for a good and reliable retouching medium is given on p. 1063 of the ALMANAC. The formula for toning with the formate of soda has been given in the last volume of the JOURNAL, and is that you are probably using. As you say you sometimes get good results, it shows that the formula is all right, and that, when you get bad and indifferent, it shows that the manipulations are at fault. Note the conditions when you get good results and follow them, then you will always get good results. The bath is better used freshly made.

**BUSINESS DISPUTE.**—A. says: "Last year I bought the business of — at this place, upon the strength of the returns for the previous two years. During the time I have had it the returns have not been equal to half that. Soon after I had entered into possession, the operator to the previous owner, whose services I did not require, opened a place close by, and, I think, has done me some injury, and thus reduced (to an extent) the returns. I had to pay for the business by four instalments, the last of which will shortly be due. Should I not be justified in repudiating this, as the returns have been less than half those represented to me?"—No; we should say not, unless you can prove that the represented takings were false, and that you were fraudulently deceived. In the case of legal proceedings, your predecessor would probably plead that your work was not so good as his, or the sitters did not like you so well and transferred their patronage to his former operator, &c. When a photographer sells his business, he cannot guarantee that his customers will remain with his successor. If the returns represented to you were honest, you have nothing to complain of.

**IODIDE OF SILVER.**—A. E. H. says: "I understand that, when silver iodide is formed in the presence of an excess of the halogen salt, it is insensitive to light. Can you inform me whether this property can be used in a wet-plate process as follows: Prepare an emulsion of iodide of silver, say, 20 grains of nitrate of silver and 20 grains of potassium iodide to the ounce of collodion. When plates are set, immerse in a ten per cent. solution of potassium iodide to ensure the thorough conversion, and then wash well. When required for use, sensitise with a twenty to thirty grain solution of silver nitrate, and expose wet. If this is practicable, cannot the emulsion be prepared by dissolving the two salts directly in equal quantity of good commercial collodion, and mixing them gradually with constant agitation? I have not overlooked the 'Daylight Process' dealt with by you a few years back, but my suggestion slightly differs from those."—We have made no experiments ourselves in this direction, and we can see no advantage in doing so. It would simply mean introducing more operations, and elements of uncertainty in the wet-collodion process without any corresponding advantage.

**COPYRIGHT.**—JOSÉ ANGO says: "I shall be pleased to obtain your opinion with regard to the following: Some time ago I sold some views taken by myself of this island to a Moravian parson, who forwarded same to a firm in Germany. They have printed thousands of copies on post cards, and are sold in this island by a merchant without my sanction, and thereby cause me to lose a great sale for my views. Could I claim damages against either the firm or the parson, as I think it extremely hard lines, as my profession cost me a good deal of money, and I never bargained for such mean tricks to be played? I may mention that I have no copyright, as I have written several times to Mr. Henry Gower, the Secretary of the British Photographic Copyright Union, and have not up to the present time received any reply. Is it necessary for me to obtain a copyright, and, if so, how can I obtain one out here?"—We are not conversant with the law as regards copyright in Antigua; but as you say you have no copyright in the photographs, you can of course obtain no recompense either from the parson or the merchant. If you wish to copyright any photographs here, send us three copies and ls. 7d., and we will make them copyright for you.

\* \* Many answers to correspondents are unavoidably held over.

DRS. LANG and Melzing, of Vienna, have succeeded in taking photographs of the mucous membrane of the stomach in the living subject. A stomach tube some sixty centimetres long, and with a diameter of eleven millimetres, is provided with an electric light at its lower end, and at the upper end is a camera. The stomach is first emptied of its contents, and, after being washed, is distended with air. Then fifty pictures or more can be taken in rapid succession in from ten to fifteen minutes. The apparatus can be turned on its axis, so that all parts of the mucous membrane can be photographed. The photographs are naturally very minute.

## EX CATHEDRA.

ELSEWHERE in the JOURNAL this week we reprint from the April number of the *Philosophical Magazine* a paper by Professor R. W. Wood, of Wisconsin University, entitled "An Application of the Diffraction Grating to Colour Photography." From this interesting paper it appears that Professor Wood has succeeded in obtaining natural-colour photographs by superposing reproductions of diffraction gratings on glass positives made from negatives obtained by the three-colour method. The finished result is viewed as a transparency through a lens. Professor Wood's method, so far as we know, is quite novel, and, given the possession of the necessary diffraction grating, appears exceedingly easy to put to the practical test. His paper, which is a very important contribution to the study of the problem of colour photography, is well worth careful consideration.

\* \* \*

THE inevitable result of a rise in price of the foreign-made papers for photographic purposes has at last commenced to

manifest itself. We understand that an English house has taken up the manufacture of paper for baryta coating, and that before long it will be in use by at least one of the firms who turn out gelatino-chloride papers, &c., in this country. The quality of the new English-made paper is said to be of the highest.

\* \* \*

IN a small portion of our issue of March 31, the word light-filters in Messrs. Cadett & Neall's advertisement was inadvertently printed throughout as light-fitters. As the "copy" from the JOURNAL was directed to be taken for use in our contemporaries, the word light-fitters was thus unfortunately reproduced that week. This explanation of the origin of the misprint is therefore due to Messrs. Cadett & Neall and their extensive clientèle.

\* \* \*

FREQUENT allusion has recently been made in these columns to the case in which a Shettleston hawker brought an action for damages against the local camera club for taking and exhibiting, without his authority, an instantaneous photograph of him whilst he was driving in a public thoroughfare. The case came before the Sheriff-substitute a few days ago, and the action was dismissed with costs. In a note the Sheriff-substitute observed, "In the view which I take it is unnecessary to determine whether the Shettleston Camera Club is properly convened to this action by calling certain of its alleged office-bearers. I am disposed to think in a small limited club that all the members should have been cited. It was further said by defender's agent that the office-bearers called were not *de facto* the present office-bearers of the Club, and, if this be the true state of matters, there can, I think, be no doubt that the action is not properly directed. However, it is better that the action should not be dismissed upon a technicality if it can be decided on the merits. Pursuer prefers a claim of damages for 150*l.*, on the ground that, without his authority, a snap-shot photograph of pursuer was taken when he was driving in a street in Shettleston, and has since been exhibited in a cinematograph exhibition. There is no allegation that the pursuer has been caricatured in any way, and, without some authority to hold a claim of damages competent in a case of the kind, I am not prepared to entertain what is a novel claim of damages. I express, in the mean time, no opinion on the question of

whether petitioner might not be entitled to obtain interdict against a photograph, obtained without his knowledge or consent, being made use of in a public exhibition. That is not the question which has to be decided in the action as laid."

\* \* \*

THE decision in the case is a common-sense one. It amounts to this: That you are legally entitled to take photographs of people in public thoroughfares and to privately exhibit them. We imagine that the same immunity would apply in the case of a public exhibition, although the Sheriff-substitute, with native caution, declined to commit himself to an opinion on the point. Still it is obvious that where the elements of ridicule or contempt are absent, and the person photographed is not libelled or damaged by the public exhibition of his photograph not improperly obtained, no ground of objection could reasonably lie. We take it that in the event of a person finding himself obliged to proceed in the courts in consequence of the exhibition of a photograph which he considered damaging to his character or reputation, an action for libel would be the course to take. The result of such an action would be decidedly interesting, as so far, we believe, the point has not cropped up in the courts.

\* \* \*

THE Committee of the Camera Club have for some time had under consideration a scheme for taking larger premises, but in the last number of the *Journal* it is stated that further consideration of the scheme is deferred, and the Club will be carried on in its present quarters as hitherto. The *Journal* also makes the following announcements:—The Annual General Meeting of the Camera Club Company, Limited, will be held at the Club House, at 5.30 p.m., on Monday, April 17. The Members' Exhibition will open on Monday, May 1; pictures for exhibition should be sent in on or before Thursday, April 27. The Ladies' Evening has been fixed for Tuesday, May 2, and it is hoped that Mr. Stroh will give a demonstration of his phonograph. The Annual Dinner will take place at the Club House on Thursday, May 4.

\* \* \*

THE Directors of the National Gallery last week issued their report for the year 1898. The report states that the Gallery in Trafalgar-square was visited by 422,913 persons on the free days during the year, showing a daily average attendance on such days (209 in number) of 2023. In addition to the above number, 30,635 persons visited the Gallery on the thirty-one Sunday afternoons on which it was opened during 1898, showing a daily average attendance of 988. The National Gallery of British Art, at Millbank, has been visited by 190,994 persons on the free days during the year, showing a daily average attendance on such days (209 in number) of 913. In addition to the above number, 41,853 persons visited the Gallery on the thirty-one Sunday afternoons on which it was opened during 1898, showing a daily average attendance of 1350.

\* \* \*

WE are informed that at the Tribunal of Commerce, Paris, on January 17 last, the Eastman Kodak Société Anonyme Française brought an action for damages against the defendants, Dr. Krügener and M. A. Schmand, for having

issued certain circulars, stating that the manufactures of the defendants surpassed the Kodak apparatus, and in other ways making unfavourable comparisons. The defendants were declared guilty of unfair competition, and were prohibited from printing or distributing in the future circulars mentioning or in any way alluding to the name Kodak or that of the Eastman Company, under the penalty of 50 francs for each infraction found. The seizure and destruction of all incriminated circulars was ordered, the defendants were required to pay a sum of 1500 francs as damages, and to publish at their own cost, to the extent of 350 francs, the judgment in Parisian and provincial newspapers.

\* \* \*

FROM Messrs. Tennant & Ward, publishers, of 289, Fourth-avenue, U.S.A., we have received the first number of the *Photo Miniature*, a monthly magazine of photographic information. The scope of the magazine is restricted to the treatment in each number of some single, but important, branch of photography, and for the first issue the subject of "Modern Lenses" has been chosen. The article occupies thirty-six pages, and gives a great deal of information which may serve as a useful introduction to the study of a larger and more complete account of the properties of modern photographic objectives. The *Photo Miniature* is neatly printed and produced, and we wish it success. It is obtainable from Messrs. Dawbarn & Ward, Farringdon-avenue, London, E.C., at the price of 6d. per copy.

\* \* \*

WE are pleased to learn that the Government of the United States are alive to the value of photography as a recorder of events of national or historical interest. It is announced that the American War Department has undertaken the compilation of a photographic history of the war with Spain. It has addressed a circular letter to all the officers in the service, asking them to contribute such prints, films, or negatives, as they may have in their possession, promising to return such loans in good condition. It furthermore asks all officers to report the names of the persons known to have carried cameras in the region of active operations, so that their aid may be sought in compiling the volume. It is the desire of the department to produce in a single volume every obtainable feature and photograph bearing on the subject. Readers of the newspapers are aware that in the exciting campaign, both naval and military, the camera played an important part, and the proposed photographic history of the war should be both complete and interesting.

#### MORE COLOUR FALLACIES.

Two months ago we devoted an article \* to the examination of a theory of colour photography which implied that, "under proper conditions" (not specified), "perhaps under all conditions," the colours of an object might impress themselves on an ordinary photographic plate, and be transmitted in turn by the negative to a sensitive positive printing surface on glass or paper. We pointed out that this theory, which was due to Mr. Romyn Hitchcock, who brought it before the

\* THE BRITISH JOURNAL OF PHOTOGRAPHY, Vol. XLVI., No. 2025, pp. 114-115.

American Association for the Advancement of Science last year, was not deserving of serious consideration in the present state of our knowledge of the phenomena of light and colour and the influences they exert on sensitive compounds. In short, the idea appealed to us, as it must appeal to every one having the least acquaintance with the philosophy of the subject, as sheer empiricism of an entirely speculative nature.

It is not a little remarkable that both here and in America the most absurd notions on the subject of colour photography emanate, not from persons who, in right of absolute ignorance of even the most ordinary photographic processes, have some claim on our compassion when they air their amusing views on the manner in which the reproduction of colour may strike them as possible of achievement, but from people who might be supposed, in virtue of their scientific position or assumed knowledge, to at least have the ability to refrain from publishing absurdly erroneous ideas on a matter which supplies considerable facilities for going wrong. In the last-mentioned class of persons we are driven to include a self-styled lecturer on physics and chemistry, Zerban by name, who is a very recent writer on the subject of colour photography.

Mr. Zerban's contribution is printed in the *Photo American* for March, and the Editor of that interesting publication evidently thinks so highly of what a lecturer on physics and chemistry has to say about colour photography that he heads it with the words "Prize Article," thus doubly avowing responsibility for Mr. Zerban's utterances. The latter possesses in some respects the elements of novelty and originality, but, we are obliged to say, at the sacrifice of accuracy. It is apparently Mr. Zerban's aim to demonstrate a close acquaintance with the theory of his subject. Now, in that aim he is conspicuously unsuccessful, for, though in the course of his preliminary observations he informs us that he has "swamped" (*sic*) "some of his most illustrious fellow-chemists" in the matter of knowledge, we fail to see how he sustains his position by the mysterious and unilluminating deliverance that "we know too little of the silver salts constituting" (*sic*) "photography." Even so; but why does Mr. Zerban allow the context of this Delphic utterance to leave us in doubt as to whether he personally knows anything at all about the silver salts, the properties of which have surely not suffered from the lack of attempted elucidation on the part of the most distinguished investigators of the time?

We said there were original ideas in Mr. Zerban's paper. Witness this description of the Lippmann process:—

"Lippmann placed a highly polished mirror or a trough filled with mercury back of his film, which is transparent and has the sensitive chemical *in* and not *on* it, as is the case of kodaks and cameras (*sic*). In this way the film is attacked by both direct and reflected light. This film fits into a holder in the camera, just as others. In front of the camera a red glass screen is placed, the shutter opened, and the film exposed to the object. This screen allows only red and yellow light to pass through it, so that only those parts of the object are photographed which contain these colours. Next the red screen is removed and another is substituted. This second screen passes all colours except blue. After this second exposure, the same film is again exposed without any screen intervening, so as to get the blue impression. Then it is removed to the dark room and developed. When finished and dried, the picture can be seen in its natural colours by looking through the film with the mirror back of it. Angels and ministers of grace, defend us!—Eds.] The mystery seems solved, but there are countless difficulties yet to be overcome. Pictures can be taken in this way, but the arrangement is tedious and requires skilful handling by an expert. Only the three primary

colours are taken into account, as the others are mere compounds that form themselves. Under the red screen, exposure of from one half to two hours is necessary, yellow a few minutes, and the last a second or two. Red light is slowest (that is why dark-room lanterns are provided with ruby glass), yellow faster, and blue quickest. This explains the difference of exposure. I have reversed this operation, but it was not successful. So much for this method."

Yes, so much for this method! According to Mr. Zerban, it is a hopeless jumble of the interference and three-colour systems of photographing colour, the mere description of which is calculated to set Professor Gabriel Lippmann's teeth on edge, if even he does not gnash them at such stupendous ignorance. In the name of the prophet, Fudge, Mr. Zerban, "demonstrator of physics and chemistry"!!

Then we come to three-colour photography. Thus Zerban:

"This is similar to Lippmann's, and was invented by Ducos du Hauron in 1878. Here coloured monochromatic glass screens are interposed, but one plate for each screen, so that three different exposures with as many orthochromatic plates are necessary. For printing, one piece of sensitised paper is used in successive prints, somewhat similar to lithography. This method, too, is complicated, although it gives good results, for great care must be taken not to shift the position of the camera during exposure, or have the plates fit inaccurately on the paper. Mr. Ives, of Philadelphia, has improved this method somewhat, but it is still deficient."

Three-colour photography "similar to Lippmann's!" And "printing on sensitive paper" for "successive prints." Ye gods and little fishes! what next? And next?

We are painfully surprised that such rubbish as this should find its way into the columns of a photographic paper, and be singled out for the distinction of a prize. A feeling of charity towards a *confrère*, whose photographic writings we have more than once perused with pleasure and profit, impels us to hope that the article in question escaped his minute notice as he passed it on to his printers. But, for the self-constituted authority on colour photography, who styles himself a demonstrator of physics and chemistry, we can find no excuse. The ignorance he so severely suffers from can only succumb to the most drastic treatment available, namely, a study of the alphabet of current colour-photography theories. When he has got through that simple lesson we do not envy him his reflections.

So often do we find it our duty to pass unfavourable criticisms upon the ridiculous ideas about colour photography that are published in the press that at times we possibly run the risk of wearying the reader. But in this case we feel no apology is due or needed. The vehicle for the arrant rubbish to which we have called attention is a photographic paper—not a mere general newspaper of whose stock in trade ignorance of scientific subjects is cheerfully allowed to form a part—but a photographic paper, which should guard its readers against quackery. And again, if we have allowed Mr. Zerban to tell our readers, in his amusing way, what the Lippmann and Ives systems of colour photography are not, the negative knowledge so obtained may not improbably be of an informative character to many who like himself have no clear ideas on the subject. Such knowledge may thus ultimately pave the way towards a tolerable understanding of what those beautiful processes really and truly are, so that, after all, it is to be hoped that Mr. Zerban will not have written his prize masterpiece in vain, and that our action in directing public attention to it will not be without advantage.

## OZOTYPE AND MARIOTYPE.

It will be remembered that, in the last Exhibition of the Royal Photographic Society, some half a dozen pictures were shown by Mr. Thomas Manly as examples of "ozotype printing in pigments." No particulars of the process by which they were produced were given beyond what appeared in the catalogue, which was, "Carbon printing without actinometer, transfer, or safe-edge, and in which the pigmented gelatine does not come in contact with a chromic salt." There was some little speculation at the time as to what the process was, and the opinions we heard generally expressed by several was that it was probably somewhat akin to the Mariotype process of a quarter of a century ago. Mr. Manly has protected his method by a patent, the specification of which and the claims it contains was published in our issue of the 31st. ult.

At the last Technical meeting of the Royal Photographic Society Mr. Manly read a paper on, and gave a demonstration of, the working of "ozotype," a brief report of which we gave last week.

From the specification and the report it will be seen that ozotype is somewhat closely analogous to Mariotype, inasmuch as it is based upon the property that an exposed film of bichromated gelatine has of communicating the light's action to another film of gelatine that has not been exposed to it at all. In order that our readers may the better understand the two processes and the difference between them, we briefly describe them, taking the older of the two methods first.

Mariotype was first brought before English photographers by M. A. Marion, in a paper read before the London Photographic Society (now the Royal) on May 13, 1873, which will be found in full on page 242 of our volume for that year. It had, however, shortly before been brought before the French Photographic Society. There are two methods of M. Marion, "Mariotype by contact," and "Mariotype by pressure," though both are based upon the same principle. It is the former that we shall describe now, inasmuch as it is that to which ozotype is the most closely allied in practice.

The ordinary single-transfer paper, as used in carbon printing, is sensitised, instead of the tissue, on a six per cent. solution of bichromate of potash, to which a little sulphuric acid has been added, and dried. It is then exposed under the negative. The printing can be watched in the same way as in silver printing, the image being a visible one of a brown colour on a pale yellow ground. When printed, the paper, with a piece of ordinary unsensitised carbon tissue, of any desired colour, are immersed in a two per cent. solution of bichromate of potash, and then squeezed together in the usual method of working the carbon process. The mounted tissue is then placed, while in the moist condition, under slight pressure for eight or ten hours. Under these conditions the continuation of the light's action goes on, by transmission, to the unexposed tissue. At the end of the eight or ten hours the print is put into the warm water, and developed just as if it were an ordinary single-transfer picture. When dried, the work is complete and we then have a non-reversed picture without transfer. No actinometer is required for timing the printing, and no safe-edge is necessary. Such is Mariotype by contact.

The manipulations in ozotype are these: Single-transfer paper is sensitised in a solution of bichromate of potash, to which sulphate of manganese has been added, and dried. It is

then printed under the negative, the image, as in Mariotype, being a visible one. It is next washed, to get rid of the unacted-upon salts, and again dried. Then a piece of ordinary unsensitised carbon tissue, together with the print, are immersed in a bath, consisting of water, 1000 parts; glacial acetic acid, 2 to 5 parts; and hydroquinone,  $\frac{1}{2}$  to 2 parts, and the two squeezed in contact and once more dried. Afterwards the print is soaked for half an hour or so in cold water. It is then developed in warm water, as in the ordinary method of carbon printing, and, when dry, the print is completed.

In Mariotype, sulphuric acid is added to the bichromate sensitising solution; in ozotype, sulphate of manganese. For mounting the tissue on the print in the former process a plain, dilute solution of bichromate of potash is used, in the latter a dilute acid solution of hydroquinone is employed. Except for the washing out of the unacted-upon salts in the latter process and the two dryings, the manipulations are precisely similar, though it will be seen that Mariotype by contact is the simpler of the two. The separate and distinct operations involved in the ozotype process are just about the same as those pertaining to the ordinary double-transfer carbon process, and the time, from beginning to end, in which a print can be completed by either of these processes is much about the same in the end.

There is no question that the ozotype process is an exceedingly interesting one, like Mariotype, and no doubt many experimentalists are trying it, for we understand that, though patented, Mr. Manly throws no obstacle in the way of those who wish to experiment with it.

Whether this process will ultimately supersede the usual method of commercial carbon printing, of course, remains to be seen, but much will naturally depend upon the quality of the results it is capable of yielding; the operations, as we have said, in ozotype are about the same as in the usual double-transfer carbon process, and more than those in the single-transfer or the Mariotype processes.

It may well be asked why the Mariotype processes have so long remained in abeyance and are almost forgotten. Such, however, has been the case with other processes that have been resuscitated and brought into practice. Pouncy's gum-bichromate process is a case in point. At the time M. Marion made his process public comparatively little interest was taken in carbon printing, either by amateurs or professionals, except by a few large firms, and it was then hampered by patent rights; therefore it attracted but little attention at that period and passed almost into oblivion.

Space will not allow us here to enter into the second process of M. Marion, "Mariotype by pressure," though it is quite as interesting as the one we have so briefly described.

---

**Municipal Installation of Acetylene.**—It is increasingly evident that, as we have before pointed out, Continental authorities do not evince the dread of this fell agent that fire insurance companies show in this country, for we read that an installation of this gas under municipal auspices has just been laid down at Schonsee in Prussia. This is the first installation laid down by authority, but it is being followed by one in Oliva, near Dantzig. We await with interest the accounts of the practical working of acetylene on a large scale, and, with some curiosity, the possible effect these public virtual recognitions of its safety will have upon the British fire offices.

**Photography and Eclipses.**—In view of the solar eclipse next year, for which active preparations are already in progress, an important discussion of photographic methods took place at the fifth ordinary meeting of the British Astronomical Association on the 29th ult. It is evident that the actual results obtained at the eclipse were far from being as satisfactory as would have been liked. Mr. Maunder read a paper on "The proper Exposure to be given for Photographs of the Corona," and in it he commented upon the extraordinary variations in the exposures given when taking the corona. He divides the photographs to be made into four classes, according to the region in which it is desired to obtain to perfection in the negatives, and with rapid plates, assuming the telescopes to act at  $f$ -15, he gives from  $\frac{1}{80}$  to  $\frac{1}{2}$  or even  $\frac{1}{4}$  second as the exposure time, one second almost marking the limit of really useful exposure, though if the long rays alone are wished for a 100 seconds may be given, the inner portion then being naturally "burnt up." Now, it is perfectly evident to any practical photographer that no amount of the "skilful development" referred to will enable the astronomer, on one and the same plate, to obtain really useful negatives of the whole area of an illuminated object the intensity of light radiated from which varies at different positions from one to eight thousand. Two ways can be devised for overcoming the difficulty. First, the coronal rays must be divided into zonal regions and the exposure selected for each particular region, the more brightly illuminated parts to be absolutely cut off with an opaque screen. Second, a glass interceptor might be devised and placed in front of the plate, and so stained or obscured in a graduated manner as to reduce the various intensities to a common value.

It may be further pointed out that no practical photographer, desiring to take faintly luminous objects such as the outer portions of the corona, would for one moment, if he could avoid it, include on the same plate and in immediate proximity to the faint illumination, another object intensely brilliantly lighted; a combination of halation and atmospheric light convection, if we may coin the expression, would tend to destroy the greater part of the possible clearness and crispness of representation looked for in a good negative.

MR. THWAITES gave his experience, which does not seem to accord with usual photographic practice. Using ordinary plates, he yet found it desirable to develop on the spot, as the plates quickly deteriorated. Again, he quoted Lord Crawford's experience given at a meeting of the Royal Astronomical Society; he took 600 negatives in countries ranging through the south of India, the Malay Peninsula, Singapore, and the coast of Borneo, and of those developed at home ninety per cent. were failures. It surely is not possible that the plates were not sealed in air-tight receptacles, yet, if such precaution were taken, it is difficult to understand the failures. Films are usually considered more liable than plates to be influenced by external causes, yet we may say we lately developed some films comprising exposures in the Mediterranean, Suez Canal, and India, all the films having travelled through this hot area, which gave perfect negatives. The films were enclosed in tin cases, the lids being sealed simply with strips of the well-known indiarubber plaster.

**Saturn's Ninth Satellite.**—This astral body, which we recently described as having been discovered entirely through photographic agency, was found on a negative taken at the Harvard Observatory at Arequipa, the telescope used being the twenty-four-inch one lately presented by Miss Catherine Bruce. The instrument, as we know, is a specially rapid one for its class, working at  $f$ -6. The four plates taken had an exposure of only two hours. None but a most powerful instrument could have picked up an object of such slight magnitude as this satellite must be. The discovery is an undoubted triumph for photography.

**Uranium Radiation.**—In a note presented to the last meeting of the French Academy of Sciences, M. Henri Becquerel describes some of his latest experiments on this subject, showing

the virtually perpetual nature of the radiations. He states that, as estimated by their action upon photographically sensitive media, the radiations given off by uranium appear to persist indefinitely in their original intensity. In May 1896, he enclosed a portion of this substance in a leaden box, thus shutting it off from any source of radiation known to science at the present time, yet the uranium appeared to exert just the same action as it did when first experimented with, before being enclosed. In two early experiments he made he appeared to discover a polarisation of the rays, but this he now entirely fails to reproduce. He notes that bodies such as glass, exposed to these rays, give off a secondary radiation similar in nature to that described by M. Sagnac as happening with X-rays.

## AN APPLICATION OF THE DIFFRACTION-GRATING TO COLOUR PHOTOGRAPHY.

[Reprinted from the *Philosophical Magazine*.]

If a diffraction-grating of moderate dispersion and a lens be placed in the path of a beam of light coming from a linear source, and the eye be placed in any one of the spectra formed to the right and left of the central image, the entire surface of the grating will appear illuminated with light of a colour depending on the part of the spectrum in which the eye is placed. If one part of the grating has a different spacing from the rest, the spectrum formed by this part will be displaced relatively to the first, and, if the eye be placed in the overlapping part of the two spectra, the corresponding portions of the grating will appear illuminated in different colours. This principle I made use of in the development of a new method for producing photographs in natural colour. I have eliminated the use of pigments and coloured screens entirely in the finished picture, the photograph being nothing more nor less than a diffraction-grating of variable spacing, the width between the lines in the different parts of the picture being such as to cause them to appear illuminated in their proper colours when viewed in the manner described.

We will take at the start three diffraction-gratings of such spacing that the deviation of the red of the first is the same as that of the green of the second and the blue of the third (the red, green, and blue in question being of the tints of the primary colours of the Young-Helmholtz theory of colour vision). If these three gratings be mounted side by side in front of a lens, their spectra will overlap, and an eye placed in the proper position will see the first grating red, the second green, and the third blue. If the first and second be made to overlap, this portion will send both red and green light to the eye, and will in consequence appear yellow. If all three be made to overlap in any place, this place will send red, green, and blue light to the eye, and will appear white.

The method that I first employed to produce photographs showing natural colours on this principle is the following: Three negatives were taken through red, green, and blue screens in the usual manner; from these positives were made on ordinary lantern slides (albumen slides are necessary for reasons which I will speak of presently). The positives, when dry, were flowed with bichromated gelatine, and dried in subdued light. The three diffraction-gratings of proper spacing, ruled or photographed on glass, were placed over these positives, and exposed to the sun or electric light for thirty seconds. On washing these plates in warm water, diffraction-gratings of great brilliancy were formed directly on the surface of the film. Albumen plates must be used, since the warm water softens and dissolves a gelatine film. Three sheets of thin glass, sensitised with the bichromated gelatine, were placed under the three positives, and prints taken from them. The portions of each plate on which the light had acted bore the impression of the corresponding diffraction-grating, strongly or feebly impressed, according to the density of the different parts of the positives. These three plates, when superimposed and placed in front of a lens, and illuminated by a narrow source of light, appear as a correctly coloured picture when viewed with the eye placed in the proper position. Perfect registration of the different parts of the picture could not be obtained in this way, for obvious reasons. I worked for a while with the thin glass from which covers for microscopical

slides are made. This gave much better results, but was too fragile for practical purposes. It then occurred to me that, if I could get the entire grating system on a single film, not only would the difficulty about perfect registration vanish, but the pictures could be reproduced by simple contact printing on chrom-gelatine plates as easily as blue prints are made. I was surprised to find that successive exposures of the same plate under the positives, perfect registration being secured by marks on the plates, produced the desired result. On washing this plate in warm water and drying, it becomes the finished coloured photograph. Where the reds occur in the original, the spacing of the first grating is present; where the yellows occur, the spacing of both the first and second are to be found superimposed; where the blues occur are the lines of the third grating; while in the white parts of the picture all three spacings are present. It seems almost incredible that, by exposing the plate in succession under two gratings, the spacings of both should be impressed (superimposed) in such a manner as to give the colours of each in equal intensity; but such is the fact. Thus far I have had at my disposal but two gratings of only approximately the right spacing, one giving the red, the other the green; with these I have photographed stained-glass windows, birds, and butterflies, and other still-life objects, the finished pictures showing reds, yellows, and greens in a most beautiful manner. By making a separate plate from the blue positive, using the same spacing as with the green, and setting this plate behind the other at an angle, I have obtained the blues and whites, the grating space being diminished by foreshortening, though, of course, perfect registration of the different portions of the picture could not be obtained.

One of the great advantages of this method is the facility with which duplicates can be made. If we place the finished picture in a printing frame over a glass plate coated with bichromated gelatine, and expose it to sunlight, on washing the plate in warm water we obtain, by a single printing process, a second colour photograph, equal to the first in every respect, and also positive. From this second copy we can print others, all being positive.

The apparatus for viewing the pictures consists of a cheap double-convex lens mounted on a little frame, as shown in fig. 1, with a

perforated screen for bringing the eye into the right position. I find that, by using a lens of proper focus, it is possible to so adjust the apparatus that the picture can be seen in its natural colours with both eyes simultaneously, since corresponding overlapping spectra are formed on each side of the central direct image. A gas flame turned edgewise, or the filament of an incandescent light, make a convenient source of light. The colours are of great brilliancy and purity, almost too brilliant in fact, though dark reds and ochres are reproduced with considerable fidelity. The pictures can be projected by employing a powerful arc light, placing a rather wide slit in the overlapping spectra and mounting the projecting lens beyond this. The pictures that I have obtained thus far measure 2.5 inches by 2.5 inches, and have been thrown up about 3 feet square. The fact that only a small percentage of the light is utilised makes great amplification difficult. Certain experiments that I have made lead me to believe that the process can be greatly simplified.

I have exposed an ordinary photographic plate in a camera under

a diffraction-grating placed in front of, and in contact with, the film. On development, we obtain a negative, the dark portions of which are broken up into fine lines, corresponding to the lines of the grating; and, on viewing this in the apparatus just described, the blue components of the picture are seen, though not so brilliant as with the transparent gelatine plate, owing to the coarseness of the grain.

I believe that, by the use of a suitable photographic plate, to be exposed in succession in the camera under red, green, and blue screens, on the surfaces of which suitable diffraction gratings have been photographed, it will be possible to obtain the colour photograph directly. The screens can be swung into position in succession by a suitable mechanical arrangement operated outside of the camera. The plate, on development, will be a negative, in the ordinary sense of the term, though, when seen in the viewing apparatus, it will appear as a coloured positive, since, on the transparent portions which correspond to black in the original, no grating lines have been impressed; consequently these portions will appear dark. The dark portions, however, where the lines are impressed, will light up in their appropriate colours. From this plate as many copies as are desired can be made by contact printing on bichromated gelatine.

Of course, it is a question whether superimposed gratings can be impressed on a plate in this manner. Judging from the experiments I have made, I imagine that the gratings on the colour screens would have to be made with the opaque portions broad in proportion to the transparent.

I have overcome the difficulty of obtaining large diffraction-gratings by building up photographic copies in the following manner. The original grating ruled on glass was mounted against a rectangular aperture in a vertical screen, the lines of the grating being horizontal. Immediately below this was placed a long piece of heavy plate glass, supported on a slab of slate to avoid possible flexure. A strip of glass, a little wider than the grating, sensitised with bichromated gelatine, was placed in contact with the lines of the grating, and held in position by a brass spring. The lower edge of the strip rested upon the glass plate, so that it could be advanced parallel to the lines of the grating, and successive impressions taken by means of light coming through the rectangular aperture. In this way I secured a long narrow grating, and by mounting this against a vertical rectangular aperture, and advancing a second sensitised plate across it in precisely the same manner, I obtained a square grating of twenty-five times the area of the original. It was in this manner that I prepared the grating used to print the impressions on the three positives. So well did they perform, that it seemed as if it might be possible in this way to build up satisfactory gratings of large size for spectroscopic work. Starting with a one-inch grating of 2000 lines, I have built up a grating eight inches square, which, when placed over the object-glass of a telescope, showed the dark bands in the spectrum of Sirius with great distinctness. No especial precautions, other than the use of the flat glass plate, were taken to ensure absolute parallelism of the lines, and I have not had time to thoroughly test the grating. The spectra, however, are of extraordinary brilliancy, and, on the whole, the field seems promising. This matter will, however, be deferred to a subsequent paper.

PROFESSOR R. W. WOOD.

*Physical Laboratory of the University of Wisconsin, Madison.*

#### AMMONIUM PERSULPHATE—ITS PROPERTIES AND USES.

The general interest which has been aroused by the introduction of this salt is excuse, if one be required, for this translation of Herr Pizzighelli's abstract of a lengthy paper by Professor Namias, who is well known for his numerous writings on photographic matters.

Namias's researches have led him to the following conclusions:—

1. Ammonium persulphate has been recommended for some years, under the name of anthion, as a hypo-eliminators, and to shorten the process of washing,\* its action being the conversion of the thiosulphate into tetrathionate. It was, however, not much used, as, like most other

\* This statement is not quite correct, anthion being the potassium persulphate. — Trans.

eliminators, it also attacked the image. The best hypo-eliminator is still running water, the only exception possible being hydrogen peroxide, which has been repeatedly recommended when it is absolutely necessary to shorten the duration of washing.

2. The applicability of this salt for the reduction of negatives, first discovered by Lumière and Seyewitz,\* cannot be too highly esteemed, as it reduces the high lights, and hardly attacks the half-tones and shadows. There had not been known hitherto any reducer which would thus give harmonious results from harsh negatives; the only process, which, however, was more troublesome, was the chlorising or bromising of the image with cupric chloride or acid bichromate and bromide, and partial development.

3. According to Namias, the method suggested by the discoverers is the best, namely, the immersion of the negative in a five per cent. solution of ammonium persulphate, when, after five to ten minutes' action, a more or less lowering of the contrasts was obtained, as the solution acted first upon the high lights and afterwards on the half-tones and shadows. A subsequent washing completes the operation. If, however, it is desirable to stop an after-reduction during washing, it is advisable to immerse the negative in a ten per cent. solution of sodium sulphite, which converts the persulphate into sulphate, which does not act on the silver.

4. Namias cannot agree with Lumière and Seyewitz's theory of the action; but, before entering upon this, he comments on the salt and its properties.

Ammonium persulphate is obtained by neutralising persulphuric acid, which is obtained by the action of an electric current on normal sulphuric acid, or by direct electrolysis of a saturated solution of ammonium sulphate. It forms a white crystalline powder, readily soluble in water (one part of the salt, two parts water). When dissolved it fizzes, perhaps the result of the evolution of oxygen. Its chemical formula is generally stated as  $\text{NH}_4\text{SO}_4$ ; to be accurate, it should be written  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  or—

Persulphuric acid and the persulphates have an energetic oxidising power, and, in the presence of a substance which can combine with oxygen, they decompose water and are converted into sulphuric acid or a sulphate, combining with the hydrogen, and set free the oxygen. Their oxidising action is not, therefore, direct, but indirect, and may be expressed as follows:—

Ferrous salts are converted into ferric, sodium thiosulphate into tetrathionate, chromous into chromic acid or chromates. This last action, discovered by Namias, may be of some importance for many photographic processes, and is as follows:—

That is to say, one molecule of chromous salt requires three molecules of persulphate in order to be converted into chromic. This can be easily verified by mixing a ten per cent. solution of chrome alum with plenty of persulphate, when, after some hours, the solution becomes completely yellow, and the chromic acid formed can be converted, by addition of ammonia, into chromate or bichromate; a slight addition of sulphuric acid hastens the reaction. This could be used in chemical analysis for the estimation of chromium.

5. Ammonium persulphate possesses, beyond its oxidising action, also another very interesting property, that of dissolving certain metals, such as zinc, aluminium, and iron, &c. This peculiar property of a neutral salt, which at first sight appears wonderful, can be explained, in that, by substitution of an atom of a metal in the molecule of the persulphate, a sulphate is formed. With zinc, for instance, the following equation expresses the reaction:—

With silver:—

6. Another peculiar property of this salt, which was discovered by Lumière and Seyewitz, is its power of reducing silver salts. They held that the grey substance which is formed when a solution of ammonium persulphate is allowed to act on a solution of silver nitrate was metallic silver, and tried to explain by this the fact why the persulphate acted from within and not from the outside of the photographic film.

Namias tried and found that, whilst there was a reducing action, it never reached the stage of forming metallic silver, but only a dark grey compound, which ought to be considered as more or less a basic subsulphate of silver. The formation of this compound is accompanied by the evolution of oxygen, and therefore one may assume that the equation is

it is not impossible that a more basic subsulphate compound forms, but never metallic silver.

The greyish-black precipitate dissolves completely and quickly in hyposulphite, and also sulphite of soda, without residue, which obviously could not be the case were it metallic silver. When boiled in water, sulphur is precipitated, and it is converted into a lower basic subsulphate, which, however, is still soluble in hypo. This last fact completely excludes the hypothesis, which also on other grounds is not feasible, that a mixture of metallic silver and silver persulphate is formed, in consequence of which, and by the action of the persulphate, the metallic silver dissolves in hypo.

If a very small quantity of silver nitrate is added to a solution of ammonium persulphate, there is no precipitate, but, by continued addition, a point arrives when precipitation commences. This proves, therefore, that a strong excess of the persulphate stops the reaction. The reaction is in any case incomplete, but takes place, however, the more quickly and the more completely the greater the excess of silver nitrate.

Namias tried to analyse the precipitate, so as to estimate the amount of sulphuric acid and silver that it contained, but, by washing it with water on the filter for a long time, silver sulphate was dissolved, so that finally there was another compound to that at the beginning. It may be assumed that the composition of the compound alters when the conditions under which its precipitation takes place are changed; according to circumstances, a compound more or less rich in silver may be obtained.

7. Whatever may be the composition of the compound, one thing is certain, and that is that the explanation of the action of the persulphate, which was based by Lumière and Seyewitz on the formation of metallic silver, falls to the ground. They held that in the interior of the image-bearing film a soluble silver salt was formed by the action of the persulphate on the silver, which salt diffused in the solution, whilst on the surface the silver salt that was formed was again reduced to metallic silver by the excess of the persulphate; the tendency to this latter reaction necessarily limits the former.

Namias now remarks that the existence of a large excess of persulphate must only result in the solution of chloride, which can only form in small quantities on the surface of the film, since, as has been shown elsewhere, the persulphate in strong excess has no continued action on a small quantity of silver salt.

We must thus assume that either the persulphate penetrates only in very small quantities into the film, or, having penetrated, could reduce it.

This would explain in any case why no great excess of the persulphate could be on the surface of the film. Assuming this, the author believes that one of the causes why the persulphate has such a small action on the surface of the film may possibly be that subsulphate of silver is deposited on the silver particles on the surface, and they are thus protected from further action. In the interior of the film, on the other hand, where the excess of persulphate necessary for the decomposition of the

\* The solvent action of this salt on the silver image was first pointed out by R. E. Liesegang.—Trans.

silver sulphate first formed is not present, the reaction may easily take place.

In the interior of the film there always remains a small quantity of the silver salt, which should be eliminated by the use of a bath of sodium sulphite. The bath makes, as already mentioned, the persulphate, which is left behind, and which would continue to act harmless.

(To be continued.)

### THE APPLICATION OF THE DIFFRACTION-GRATING TO PHOTOCHROMY.\*

A PAPER by Mr. R. W. Wood, in the *Philosophical Magazine* for April 1899,† reminded me of a principle which might possibly be made use of in direct photochromy. The application of this principle occurred to me many months ago—certainly before June 1898.‡ Mr. Wood's method, as described in his paper, is "indirect," or "composite." The use of the gratings is only subsidiary, i.e. for illuminating purposes, and the original use of three-coloured screens is necessary.

The obligation to use colour screens in order to separate the primary colours, so that each may be treated separately, makes a process a composite one.§ In a direct process coloured light itself exerts an action upon the sensitive medium, which is different from that exerted by light of another colour. The earliest satisfactory experiments on photochromy (those of Seebeck, followed up by Herschel, Hunt, Bequerel, Poitevin, and others) probably relied to a great extent for their effect on interference phenomena|| of the same nature as those at which Lord Rayleigh arrived theoretically, and Lippmann experimentally.

The fundamental point upon which any process of direct photochromy must depend is the substitution of position of substance in the film for colour; each colour must be capable of producing such a modification in the film as may be preserved by after-processes, such as development (i.e. changes in the mode of deposit, that is, the position of particles). In Lippmann's process the only physical property that distinguishes rays of different colours—wave-length—was taken advantage of, and by this well-known method layers were formed in the film which corresponded to the wave-length of the light impressing the film at that point. Thus we see that position of the silver particles is substituted for the impressing colour in Lippmann's method.

Provided that there is no means of producing permanent photochromes by the direct chemical action of light, which of course cannot be said to be impossible, though it is highly improbable, it is necessary to take advantage of the wave-length of light for a direct process. If no direct pigmentary process is used, the photograph must remain monochromatic in the sense of not exerting any selective absorption on the rays of light, and hence the resultant colours, if they depend on wave-length, must be produced by position, corresponding to wave-length, of the particles forming the photographic image.

We have seen that Lippmann's process is one method of effecting this, a *réseau à profondeur* is formed of silver layers in the transparent film. From these considerations it occurred to me to inquire whether there could be any other "method of position" depending on similar, the only possible, considerations.

It is well known that, when monochromatic light passes through a narrow slit in an opaque screen, it is diffracted, and, if the diffracted light is received on a white screen or viewed through a small telescope,¶ a band of light of that colour is seen, and right and left of it a series of similar bands, gradually diminishing in brightness and separated by dark bands.

The breadth and closeness of these bands are functions of the wave-length; the bands are narrower and nearer together the shorter the wave-length.

\* I have used the term "photochromy" as being more general in meaning than "heliochromy."

† "An Application of the Diffraction-grating to Colour Photography."—*Phil. Mag.* [5], xlvii. 366-373, 1 fig.

‡ I believe the use of a diffraction-grating occurred to me after some correspondence with Dr. Joly, of Dublin, on a certain modification of his method. The modification depended on the use of a coarse grating, but did not depend upon diffraction. The connexion was a slight one, depending on the word "grating." The behaviour of coloured light when passed through a slit immediately suggested itself, and the connexion between the bands and the notion that I had previously formed of the foundation of direct photochromy—the substitution of position of the deposit for colour—then appeared (see below).

§ I do not by any means intend to say that the use of a coloured screen, *per se*, makes the process a composite one, even when the screen or screens are necessary for viewing the object in colour, but that a process is composite when it depends on a theory of colour vision. This point will be dealt with subsequently.

¶ This, apparently, was the view of Zenker (*Lehrb. de Photochromie*, 1868), and the independent view of Lord Rayleigh (*Phil. Mag.* 1887).

¶ If the aperture is very small, the diffraction figure may be viewed by the eye alone.

If the screen is replaced by a photographic plate, there will be, on development, bands of deposit whose breadth and closeness depend on the light used—in other words, position of the particles in the film takes the place of the original colour.

Now, if a coloured image is formed by a lens on a plate and a grating interposed a short distance in front of the plate, the image will be split up into minute bands corresponding to the wave-length at any point. In fact, new gratings whose "rulings" correspond to the colours at the various points of the picture would apparently be formed. In this case the picture, placed in front of a biconvex lens illuminated by a narrow source of light, and viewed in the proper position, would appear in natural colours.

The process will shortly, I hope, be under experimental trial.

In this paper the view of direct photochromy taken is different from that of Captain Abney. Captain Abney would only call a photochrome "direct" if its colour was due to pigments, that is, if it depended on absorption. This removes from the category of "direct" processes those based on interference or diffraction, but would, apparently, include such a process as that of Graby.\*

A more fundamental classification of processes is into those which depend on the preliminary and artificial separation of the impressing colours, such as the different applications of Clerk-Maxwell's idea, and those which do not, i.e., those which do not depend upon any particular theory of colour vision. The former composite process is certainly indirect; the latter is direct in the sense of all colours being treated by one process on one plate. Graby's pigment process is then more indirect than Lippmann's. Furthermore, that colours produced by absorption have any more objective reality than those produced by interference, is, physically speaking, a delusion. It is easy to see how this mistaken notion arose, but that it should form the basis, as it does for some people, of a classification of photochromic methods is absurd. The further consideration, however, of the fundamental principles of photochromy and their bearing on the classification of different processes is left for another communication.

PHILIP E. BERTRAND JOURDAIN.

### A CHEAP SUBSTITUTE FOR PLATINOTYPE.

THE following abstract of a paper by Herr Vollenbruch, which appears in the *Deutsche Photographen Zeitung* may be useful to those who wish to experiment with a cheaper paper, which according to the author is specially suitable for subjects with deep blacks, as it will give vigorous prints full of detail even from flat negatives.

The raw paper, which should be pure, is first immersed for two minutes in the following bath, which should be warmed:—

Distilled water.....	1000 parts.
Ordinary gelatine .....	5 "
Citric acid.....	3 "
Chrome alum solution (1 : 20) .....	50 "
† Aluminium solution.....	7 "

After immersion the paper should be hung up to dry.

The sensitising solutions are:—

No. 1.	
Distilled water .....	100 parts.
Gelatine .....	0.5 "
Salicylic acid .....	0.05 "

No. 2.	
Distilled water .....	100 parts.
Green ammonio-citrate of iron.....	20 "

No. 3.	
Distilled water .....	80 parts.
Silver nitrate.....	10 "

No. 4.	
Distilled water .....	100 parts.
Uranium nitrate.....	20 "

According to the proportions of these solutions the results differ, more silver gives soft prints and more iron hard prints. Reduction of uranium gives browner, and increase gives more blue-black tones. The following proportions gives the best results with a normal portrait

\* Briefly described in the *Photogram* for February 1897.

† This solution is made by dissolving 3 parts of aluminium in a mixture of pure nitric acid 18 parts, water 18 parts, and when dissolved sufficient water should be added to make 140 parts in all.

negative, and the tone of the picture is a greyish-black, which cannot be distinguished from platinotype :—

No. 1 .....	2 parts.
" 2 .....	2 "
" 3 .....	4 "
" 4 .....	4 "

The solutions must be mixed in the above order, or else the mixture will be cloudy. The solution should be poured on to the paper and then distributed with a pad of cotton-wool or round brush, and the marks evened out with a softener. The paper must be quickly and evenly dried, and will then keep for four days if protected from light and damp, but it is better to use it fresh.

The paper must be prepared and manipulated in yellow light. The paper should be exposed till the half-tones are faintly visible, and then immersed in the following developer :—

Distilled water.....	700 parts.
Ferrous sulphate.....	30 "
Acetic acid .....	10 "

When sufficiently developed, the print should be placed in a clearing bath of one per cent. solution of nitric acid for three minutes, and then immersed in the following fixing bath :—

Water .....	1000 parts.
Hypo .....	180 "
Sodium sulphite .....	25 "
Sulphuric acid ..	3 "

The hypo and the sulphite should be first dissolved, and then the sulphuric acid slowly added, with constant stirring. As the prints lose considerably in printing, they must be considerably over-developed.

For those who prefer to work with a real instead of an imitation platinotype, the following notes for the preparation of such papers may be useful. The raw paper is, as is well known and has been frequently described, given a preliminary sizing with arrowroot or gelatine. Such paper can be obtained commercially. If it is desired to make this oneself, which is not worth while unless a large quantity is used, the following formulae should be used :—

#### I.—GELATINE SIZING.

Take of a good, soft gelatine 42 parts, and allow to soak in 6000 parts of soft water, then heat to 60° C., and stir well till the gelatine is dissolved, and then allow to cool. Dissolve also in 2000 parts of water, alum (potash), 28 parts; oxalic acid, 4 parts; and finally add 1000 parts of ninety-six per cent. alcohol. Mix the two solutions and pour into a big dish while still warm. In this solution the sheets of paper should be immersed and allowed to remain for three minutes, and then hung up to dry. When thoroughly dry, the sheet should be again immersed for three minutes and then hung up from the opposite end to the last time.

#### II.—ARROWROOT SIZING.

Rub up 15 parts of arrowroot in 100 parts of water, and then pour it into 500 parts of boiling water, and add the part of previously swollen gelatine. The solution should be allowed to cool, and the sheet tacked on to a board, and then coated evenly with the mixture, and then hung up to dry. When dry, the operation should be repeated, and the paper hung up to dry from the opposite end, as suggested above.

#### THE SENSITISING SOLUTIONS.

##### (a) Iron Solution.

Dissolve 20 parts of ferric oxalate in 80 parts of distilled water; when dissolved, filter and add 0.8 parts of lead oxalate; shake till dissolved, and add 2 parts of oxalic acid.

##### (b) Platinum Solution.

Dissolve 10 parts of chloro-platinite of potash by the aid of heat in 60 parts of distilled water.

##### (c) Chrome Solution.

Bichromate of potash.....	1 part.
Distilled water.....	50 parts.

For blue-black tones for a normal negative take

Solution a .....	6 c. c.
Solution b .....	4 c. c.

For flat negatives, add from one to ten per cent. of solution c. If brown pictures are required, add to the above quantity 6 to 8 drops of a five per cent. solution of mercuric chloride.

The solution is now spread on a sheet of paper, and evened out by a badger's-hair softener, and quickly dried. The dry paper must be kept in a calcium tube. The further treatment of the paper is well known.

#### WIDE-ANGLE PHOTOGRAPHY IN ASTRONOMY.

To the pages of our contemporary, *Knowledge*, for April, Mr. E. Walter Maunder, F.R.A.S., contributes a very interesting article on the above subject. He points out that one of the first results of the great scheme of an international photographic survey of the entire sky was a rather curious one. There was a sensible diminution in astronomical activity, at any rate in England, apart from the more or less routine work carried on by the great public observatories. This would seem to have resulted from a vague, unspoken, yet powerful impression that the great photographic revolution which was in progress had rendered the older methods of observation more or less obsolete, and in particular had doomed the amateur astronomer to uselessness and extinction.

In all probability, no one man ever formulated this impression into a categorical statement, but for a time it certainly had its effect. Nor was it without some plausibility, for it was a new thing to see an astronomical enterprise set on foot of so gigantic a nature that no single observatory, however fully equipped and richly endowed, could hope to deal with it. Nothing less than the association of something like a score of the largest observatories in the world could cope with it.

The discouragement did not last long, and there were some who never felt it. Dr. Isaac Roberts, for instance, was very quick to realise that the international scheme had by no means annexed the whole of the photographic universe, and he promptly carved out a territory for himself, which he has developed with a thoroughness and a success which requires no setting forth to the readers of *Knowledge*, who have had the privilege of studying so many of his wonderful revelations of world systems in the making.

Here, then, are two great photographic surveys with entirely different objects, carried out by very dissimilar instruments, but both carried out so effectively as to render any thought of competition quite out of the question, save to extend Dr. Roberts's cluster and nebular studies to the Southern Pole.

Do these two great schemes cover the whole of possible photographic research? It might almost appear that with some astronomers there had been a feeling that this was indeed the case. If so, others have not been wanting who have been most active in opening out new lines of work.

Among the pioneers of new photographic enterprise two names are pre-eminent, those of Professor Barnard and Professor Pickering. The impetus which the former has given to the use of the portrait lens in astronomical photography is well known, whilst the latter has been especially fertile in devising new departments of work and new forms of telescopes to carry them out. The present number of *Knowledge*, for instance, has an article from him on the use of photographic telescopes of extremely long focus. But we would now specially refer to the recognition by Professor Pickering of the necessity, not only for one great survey of the sky, carried out once, and once for all, but for surveys made in a short time and repeated at frequent intervals. Such surveys are useful for several purposes. The detection of new planets, of variable stars and Novæ, can only be satisfactorily carried out by schemes of which such frequent surveys form an integral part. Professor Pickering, therefore, early devised an ingenious method by which the same plate might be exposed to many different parts of the sky and record the stars in each region in so distinctive a manner that no confusion need take place between the different images from each.

There are two fields of work in which the necessity for embracing a large area of the sky upon a single plate is even greater than in that of the search for variables or Novæ, and yet in which the device of repeated exposures would be absolutely useless. These are the two departments of the study of general stellar distribution and of meteor observation.

The former subject was one in which Mrs. Maunder took a great interest. It was apparent to her that fields of five or ten degrees in breadth were insufficient for the purpose of dealing with some of the problems of sidereal architecture. Regions much wider must be brought together upon a single plate, and that, too, without serious distortion, if the work was to be carried out in the most effective manner. There did not seem to be any lens in the market meeting this requirement until Mr. Dallmeyer, whose work as a photographic optician is so well known, brought out his Stigmatic lens, covering an unusually wide field. Consequently she applied to Mr. Dallmeyer for one of his lenses, immediately upon their details being published, that is to say, early in 1897. It was with this lens—1½ inches aperture and 9 inches focal length—that the photographs were taken of the solar eclipse of January last year, which appeared in *Knowledge* for May 1898. The lens was, however, not procured for eclipse work, but for the charting of wide sky areas; its employment in eclipse work was incidental only, and a portrait lens would probably have been more effective, since a considerably higher ratio of aperture to focus might have been obtained.

Of the admirable illustration which accompanies the article, Mr. Maunder remarks: The plate may serve to illustrate two of the uses to which a lens of this kind might be put. The field shown is thirty-seven degrees in side, fifty degrees in diagonal, and includes one-thirtieth of the area of the entire sphere. The plate was chosen for reproduction quite at random, and is far from being the best available. Nevertheless, it cannot, I think, be in the least contested that it shows the largest field, by much the largest field, of stars defined throughout that has ever yet been published.

In finally summing up this new departure in stellar photography, Mr. Maunders remarks that it offers the following advantages. Considered merely as photographs of the heavens, a set of forty plates of the same angular field as the one here shown, but of larger scale, would provide a more complete map of the heavens than any we yet possess, in exceedingly small compass and at very little trouble or expense. The scrutiny of such a set of plates would give us the fullest possible development of that method of attack of the great sidereal problem which Herschel first attempted in his gauges. Indeed, a vast amount of information as to sidereal structure would result from the mere inspection of such plates. Their value in the work of discovery is most obvious. The systematic employment of wide field plates at a number of observatories would ensure the record of all asteroids, comets, and Novæ within the limits of magnitude recorded; whilst the ingenious methods which Prof. Pickering has devised will bring about nothing short of a revolution in the discovery of short-period variables and the observation of meteors. Much of this work, too, can be done with lenses of small size, and therefore little cost, and so lies quite within the powers of many owners of small observatories. For instance, two friends situated north and south of the equator respectively might easily, and at a trifling expense, bring out not only a complete chart of the heavens, embracing over a million stars, but might bring out a new edition every year.

#### ROCHDALE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

On Friday afternoon last the first public Exhibition of the Rochdale and District Photographic Society was opened in the large room at the Lyceum, Baillie-street, Rochdale. The exhibits numbered 392, and many of them were decidedly handsome—charming in choice of subject, clear in reproduction, copious in illustration of detail, and highly artistic in finish, mounting, and framing.

Apart from the work entered for competition, there were on view forty-eight photographic pictures lent by members and friends, and several of these were much admired by the Judges. Prominent among them was *On the Beach, Hoylake*, a lovely seascape enlargement by Mr. E. Wilman from a negative taken by Mr. H. Bamford, the Secretary of the Society. This view was labelled, "The Judges wish to express their pleasure in the good work of this exhibit," which is of course quite sufficient to show that it would have been a prize-winner if entered for competition. In this section there were also eight beautiful specimens of hand-camera work in cloud, wave, and landscape studies by Mr. J. F. Spencer. Half a dozen of these pictures, illustrating Blackpool by night, had apparently been taken from the celebrated North Pier in that popular resort. The charming effect of the electric light along the front, round the big wheel, and up the tall tower, and its glittering reflection on the dark, heavily rolling waves were excellently reproduced. Another exhibit which attracted much attention was *Reaping*, shown by Mrs. C. M. Royds, wife of Colonel C. M. Royds, M.P. This would probably be considered a perfect picture were it not for the fact that a long, gaunt, dark tree trunk, cut off at the lower branches in such a weird fashion as to suggest the outline of a galloos, obtrudes itself in the foreground. Mr. F. Greenwood showed a highly interesting collection of views of old local buildings and also four local geological photographs. These latter were taken by Mr. Greenwood for the British Association collection, in association with the geological survey of the British Isles. The loan collection comprised likewise a fine enlargement of a photograph of the scene in the Rochdale Town Hall square on Jubilee Day, 1897, by Mr. A. E. Crowther; some beautifully clear studies of still and animal life, by Mr. G. A. Close; and a finely finished half-dozen local views by Mr. W. Ingham.

#### THE JUDGES' AWARDS.

There were nine prizes offered by the Society, three in each of the three classes open to competitors, and, in awarding these, the Judges (Mr. Gray, of the Rochdale School of Art; Mr. R. M. Jones, and Mr. John Schofield) had considerable difficulty. After prolonged consideration, they placed the winners as follows:—

Landscape, River Scenery, or Seascape.—1, *Evening on the Conway*, Mr. E. Ashworth; 2, *The Old Bridge, Smallshaw*, "Spots" (Mr. Turner); 3, *At Rest*, Mr. E. Willman.

Architecture.—1, *Conway Castle—Inner Gateway*, Mr. J. A. Grindrod; 2, *Inner Gateway, Conway Castle*, Mr. E. Ashworth; 3, *Old Front, Belfield Hall*, Mr. J. A. Grindrod.

Any other Subject.—1, *Animal Studies*, Mr. G. A. Close; 2, Various, Mr. J. S. Johnson; 3, *Flower Studies*, Mr. J. S. Johnson.

In Class I. Mr. Ashworth's successful effort was a remarkably good attempt to illustrate a quickly passing phase of nature, in which sunshine makes a feeble attempt to penetrate a mass of storm clouds. "Spots" view of the old bridge at Smallshaw shows light and shade remarkably well, and its trees suggest more life than can be discovered in the ordinary photograph. *At Rest* is good in foreground, but lacking in distance and sky effects. This entry was closely pressed by Mr. William's *Woodland Solitude*, which was, however, considered the worse for the too prominent appearance of tree foliage at one corner. Two other series—each *Conway Castle*, by Mr. J. A. Grindrod—were spoilt by the sky being simply a plain white patch, absolutely destitute of suggestiveness. The first and second prize-takers in architecture were similar views, the first being superior in perspective and evenness of

shade. In Class III. Mr. Close won his award with a lifelike reproduction of the head of the famous "Harry R." Mr. Abel Fletcher's trotting wonder; Mr. Johnson won the second prize with a picture of juveniles bathing; and the third with an exquisite representation of tulips, narcissi, and daffodils.

On Friday night the Exhibition was formally opened by the Mayor (Councillor Ashworth). There was a fairly large attendance. Mr. Ashworth spoke of the Exhibition in eulogistic terms.

A vote of thanks to the Mayor was passed, on the proposition of Mr. H. Bamford (Secretary), seconded by Mr. Worrall.

During the evening about 200 photographs of American scenery, &c., were thrown upon the screen by means of a powerful oxyhydrogen lantern, managed by Mr. H. Bamford. The views were described by Mr. George Smith.

The Exhibition was reopened on Saturday, when there was a large attendance of the general public. In the evening there was another lantern exhibition, when the Society's prize slides, illustrating a photographic trip down the river Wye, were shown.

#### THE GRAPHIC PHOTOGRAPHIC COMPETITION.

We have been asked to announce that the previous photographic competitions organized by our contemporary, the *Graphic*, have met with such great success, and have attracted so much interest amongst amateur photographers, who sent in many thousand contributions, that the Directors have decided to hold a third competition. There will be thirty-four prizes: First prize, 20*l.*; second prize, 10*l.*; third prize, 5*l.*; fourth prize, 5*l.*; ten Kodak cameras worth 3*l.* 6*s.* each; and twenty Kodak cameras worth 1*l.* 1*s.* each.

The prize photographs will be published in the *Graphic*, together with any others which the Judges think worthy of special mention. The fee of one guinea will be paid for each photograph reproduced, with the exception of the prize photographs. At the last competition a large number of photographs were selected by the Judges for publication and special mention in addition to the prize photographs. The rules are:—

1. No competitor to send in more than six photographs, whether mounted or unmounted.
2. In every case a stamped addressed wrapper must be enclosed for the return of the photographs.
3. Acknowledgment will be made in the *Graphic*, week by week, of all photographs received.
4. Photographs will be received any time up to June 1, 1899.
5. The name and address of the sender, and the title of the subject, should be legibly written on the back of each photograph.
6. Photographs may represent either figures, land or seascapes, animals, architecture, &c.
7. Every endeavour will be made to return unused photographs, but the Manager will not hold himself responsible for loss or damage.
8. All communications to be addressed to the Manager of the *Graphic* Amateur Photographic Competition, 190, Strand, London, W.C.

#### ALPINE CLUB'S EXHIBITION.

UNTIL the 27th inst. an Exhibition of Alpine photographs will be on view at the Club-rooms, 23 Savile-row, W. It is well worth a visit even by those photographers who, like ourselves, sigh in vain for an annual holiday among the crags and peaks of Central Europe. If we remember aright, we have seen two previous exhibitions of work by members of the Alpine Club. Our impression is that photographs of the soot and white-wash kind were by no means inconspicuous on those occasions. Alpine scenery, we should imagine, lends itself peculiarly to the production of photographs having an excessive amount of contrast, especially in the hands of a beginner. But there is little, or nothing, of this sort of thing in the present Exhibition, which is mainly the work of those who may be looked upon as veterans in respect both of photography and Alpine travel.

Some of the photographs are really wonderful examples of the ability of the sensitive plate to record the infinite range and delicacy of gradation which the searching lens discerns in the Alpine snowfields. Of those whose work struck us as being distinguished by an almost flawless technique, we may mention the names of Mr. Clinton T. Dent (quite an old hand), Mrs. E. Main (her ice-crystal studies are strikingly beautiful), Mr. H. Speyer, Mr. Sydney Spencer, and Mr. Edward Whymper, the latter, of course, a past master. Captain Abney is a contributor, and there are some Spitzbergen views by Sir Martin Conway. The familiar names of Loppé and de Dechy are also attached to work.

Alpine photography is evidently a most comprehensive term, for in this Exhibition there are photographs taken in Canada, one at Beachy Head, India, the Caucasus, &c. Messrs. Harrington & Co., of Darjeeling, are responsible for a tele-photographic view of the Himalayas taken from a distance of ninety miles. If we mistake not, this is a record in long-distance photography. Dr. Tempest Anderson has an excellent enlarged view of Mount Vesuvius in eruption—scarcely an Alpine photograph, but, nevertheless, an extremely interesting one. The life that is lived in Alpine and polar regions is here and there shown; and, from whatever point of view the Exhibition is regarded, it must be conceded that it is full of fascination to the photographer as well as to the Alpine tourist.

## JUDGES FOR THE FORTHCOMING R.P.S. EXHIBITION.

THE nomination paper for Judges of the Royal Photographic Society's Exhibition, to be opened next September, has been issued. It is unfortunate that the plan of placing the paper at the back of the Society's *Journal* is still adhered to, for it thus escapes the notice of a very considerable number of members. In a measure this method of circulating an important document must be held responsible for what was nothing less than a fiasco in connexion with last year's Judges, only the exact number required being nominated by eight members so that the general body were not called upon to make a selection by vote.

There is a strong feeling in the Society that last year's apathy in regard to the election of the Judges should find no repetition next autumn. In order to prevent the possibility of its recurrence, several members have already decided to send in nomination papers bearing a list of names previously agreed upon. It is felt that, if the gentlemen whose names are given below accept nomination, and are successful on the ballot, the Exhibition will be judged by a set of men in whom the Society and exhibitors will have the greatest confidence. It may be pointed out that Mr. W. L. Wyllie is an old friend of the Society, and is highly esteemed by its members. The other eight gentlemen are, of course, members who are too well known to need particular reference beyond this: that in the Pictorial Section an assertive Salon element that has found its way there before is not now to be seen.

The suggested list for nomination is as follows:—

Pictorial Section.	Technical and Scientific Section.
Harold Baker.	Captain Abney.
Dr. P. H. Emerson.	T. Bolas.
Colonel Gale.	Chapman Jones.
J. B. B. Wellington.	
W. L. Wyllie, A.R.A.	

Members at a distance will be safely guided if they make the foregoing nominations. The nomination paper should be returned to the Secretary of the Society, 12, Hanover-square, by Thursday, April 20, at 12 (noon).

## Our Editorial Table.

## THE AVERY BACKING TRAY AND PAD.

G. Houghton & Sons, 89, High Holborn, W.C., and H. Lamplough, Limited, 167, Strand, W.C.

A CAPITAL device for facilitating the backing of plates has just been introduced by Mr. John H. Avery, the well-known photographer. It is in the form of a folding tray, and its advantages are thus succinctly described: A plate (no matter of what size) may be coated with the medium, without being once touched with the hands after having been placed in the tray, and, as the frame keeps the edges of the plate clean and free from backing, there is no risk of getting the backing on the hands. There is no possibility of the backing finding its way to the film side of the plate, no chance of dropping or breaking the plate, and therefore no nervousness in applying. It is also claimed to be indispensable for isochromatic plates, because it allows the plates to be backed with safety away from the light, and the plates may be left to dry in the frame, thus excluding any possibility of fogging. The manner

of its use will be understood from the instructions, which are to lift up the hinged frame, place the plate in the slot on the lower tray, let down the frame again, and, pressing the end fairly firmly with the left hand, apply the backing with the right hand in the ordinary manner. The Avery backing frame is a neat and useful piece of apparatus, which will be highly appreciated by those who desire to avoid messiness in the backing of their plates. In the matter of convenience, it will soon repay its cost.

A handy adjunct to the backing tray is the Avery backing pad, which is a washable, durable pad, made of the finest rubber sponge, and mounted on a polished wood handle. It yields a smooth, even layer all over the plate, and enables the backing to be spread thinly, thus ex-

pediting the drying process. The pad should be washed in cold water as soon as done with, and allowed to dry for future use. Frame and pad are well worth purchasing, for our use of them shows them to be exceedingly handy.

*Le Microscope et son application à la Photographie des infiniment Petits* is the title given to a practical treatise on photo-micrography by M. L. Mathet. The work is published by O. Mendel, of Rue d'Assas, Paris, and is, of course, in French. It occupies nearly 260 pages, and has many very fine collotype reproductions of photo-micrographs (not micrographs as they are termed in the book) made by the author. Although it tells us nothing new, the book is excellent and exhaustive.

*Picture-taking and Picture-making* is the title of an elegantly produced little volume which is being issued by Kodak, Limited, 43, Clerkenwell-road, E.C. In the course of about 120 pages, which are adorned by a number of excellent illustrations, the beginner is taken through the various operations of photography. A word of special acknowledgment is due to the Company for including working instructions for the platinum, carbon, bi-gum, and other processes in the volume, which others besides users of the Kodak specialities will find of real service as an introduction to the study of photography.

## CATALOGUES RECEIVED.

R. & H. Robbins, Exchange-street East, Liverpool.

MESSRS. ROBBINS' catalogue extends to about fifty pages, and contains mention of a selection of photographic apparatus and material such as amateurs are likely to require. The catalogue is well printed and got up.

Ross, Limited, 111, New Bond-street, and 31, Cocks-pur-street.

MESSRS. ROSS, LIMITED, are issuing a thirty-two page supplement to their 1899 catalogue, in which the firm's latest specialities in lenses, apparatus for optical projection, &c., are fully illustrated and described.

W. Broome, 6, Denman-road, Peckham, S.E.

MR. BROOME'S catalogue particularises various kinds of lenses (notably the casket form), cameras, shutters, &c. In favour of the quality of his lenses many testimonials are quoted.

MESSRS. R. & J. BECK, of 68, Cornhill, E.C., are issuing a neatly produced catalogue of the Frena hand camera, the uses and advantages of which popular instrument are fully described. Moreover, there are fourteen capital half-tone reproductions from Frena negatives, which show that the capabilities of the camera are of the highest. The Frena catalogue is sent free to applicants, and it should be in possession of all devotees of film photography.

## News and Notes.

PHOTOGRAPHIC CLUB.—April 19, Gloucester Cathedral. Slides by Mr. F. H. Evans.

ROYAL PHOTOGRAPHIC SOCIETY.—Photo mechanical Meeting, April 18, at 12, Hanover-square, at eight p.m. "Apparatus for Half-tone Process Work."

VISITORS and residents of Brighton will be glad to hear that a dark room, which will be available for amateurs and others, with accommodation for development of plates, films, &c., as well as changing, has been opened at the Sussex Drug Company's, Limited, well-known Central Depot, 135, Queen's-road, Brighton.

MR. J. HUBERT, F.R.P.S., the well known photographer, formerly of Mare-street, Hackney, has recently changed his address to 304, Regent-street, W. Mr. Hubert, who is the author of a book on *The Art of Retouching*, undertakes negative and positive retouching as well as portrait painting for the profession, in addition to the ordinary branches of portraiture, outdoor photography, miniature painting on ivory, and so forth. Many eminent personages have given Mr. Hubert testimonials for his work, to which we ourselves have before now favourably referred.

BEVERLEY PHOTOGRAPHIC EXHIBITION.—The following is the list of awards: Open Classes.—Landscape, Seascape, and River Scenery: 1, J. Page Cloft, Birmin'gham; 2, A. J. Jeffreys, Ohelmsford, and C. M. Wane, Edinburgh; 3, G. J. T. Walford, Peckham Rye, London. Architecture: 1, H. W. Bennett, F.R.P.S., London, W.C.; 2, withheld; 3, F. Dovaston, Oswestry. Portraiture and Figure Studies: 1, Charles Speight, Kettering; 2, John Stuart, Glasgow; 3, J. Chadlin, Taunton, Devon. Instantaneous Hand-camera Work: 1, W. Fisher Ward, Bawtry; 2, J. Kearney, jun., Liverpool; 3, W. E. Inston, Liverpool. Enlargements: 1, F. Woollons, Hull; 2, A. G. Peck, Hull; 3, C. M. Wane, Edinburgh. Lantern Slides: 1, A. E. Smith, Kingston-on-Thames; 2, J. Kearney, jun., Liverpool; 3, W. E. Cowan, Newcastle. Painting, Sketching, &c.: 1, W. R. Duffill, Beverley; 2, Miss Bainton, Beverley; 3, T. H. Flather, Scarborough. Members' Classes.—Landscape, Architecture, &c.: 1, Thomas Tanfield, Beverley; 2, Rev. W. E. Wigfall. Portraiture and Figure Studies: 1, T. B. Barton, Beverley; 2, J. C. Cook, Beverley; 3, Thos. Tanfield, Beverley. Excursion Work: 1, T. Tanfield, Beverley; 2, withheld; 3, G. Dawson, Beverley. Enlargements: 1, Rev. W. E. Wigfall, Beverley; 2, withheld; 3, T. Tanfield, Beverley. Lantern Slides: 1, withheld; 2, Rev. W. E. Wigfall; 3, T. Tanfield.

**A NEW GUN CAMERA.**—A new gun camera, probably the finest ever built, is being constructed in Chicago by William Gaertner for the Smithsonian Institution at Washington. The specifications required that the instrument should be capable of making a successful exposure in one six-hundredth of a second. It is hoped that this speed will be increased, so that a good negative may be obtained by an exposure of only a thousandth of a second. The principal purpose for which this camera was designed is to serve the photographing of aerodromes, with which Professor S. P. Langley, Secretary of the Smithsonian Institution, is conducting elaborate scientific experiments in an attempt at the solution of the problem of aerial flight. The instrument is provided with a delicate measuring apparatus, by which the precise angle at which the camera is tilted at the moment of exposure is known to the operator, and is also photographed on the plate. This device will enable scientists to determine, under given conditions, the exact location and elevation of the object photographed.—*Scientific American*.

**NOVELTIES FOR THE PARIS EXPOSITION.**—If the Management of the Paris Exposition fulfils its promise, no small number of technical marvels will be revealed to the public in 1900. First of all there will be Czapanik's much-heralded telestroscope, an instrument which, by the aid of selenium, is said to have solved the problem of electrical vision. The telestroscope will, however, find a rival in the telautograph, invented by Anton Pollak, a Hungarian engineer. The telautograph, it is claimed, provides a means of receiving messages sent from one station to another in exactly the same form in which they were transmitted. The idea in itself is old, but the inventor is said to have devised an apparatus which is entirely different from its predecessors. Pollak claims to have solved the problem by using selenium, a metal which is unique in possessing the property of conducting electricity with a resistance which varies with the intensity of the light that falls upon it. The varying illumination is produced by treating the written telegram in a peculiar manner, and the variations in resistance effected by the selenium are communicated to a conductor to produce an increase and decrease in the intensity of the current passing therethrough. According to Uhlard's *Wochenschrift*, the Vereinigte Elektrizitäts-Aktiengesellschaft, of Budapest, has applied to the Management of the Exposition for space in which to exhibit the apparatus. An imperfect model is said to be in tolerably successful operation, and to be able to transmit in one hour 144 telegrams, each four inches by two inches, upon which space any number of words or characters can be inscribed.

**RE THOMAS YORK MORTER**, photographer and photographic dealer, carrying on business as "T. & E. Morter," at 8, Queen-street, Colchester.—The public examination of the above-named debtor took place at the Colchester Bankruptcy Court on April 7, before the Registrar (Mr. Henry Goody). The statement of affairs filed by the debtor disclosed gross liabilities amounting to 427*l.* 4*s.* 2*d.*, of which 351*l.* 15*s.* 6*d.* was expected to rank for dividend, 342*l.* 15*s.* 6*d.* of the latter sum being due to sixty-three unsecured creditors. The assets were estimated at 131*l.* 18*s.* 7*d.*, leaving a deficiency of 337*l.* 16*s.* 11*d.* The unsecured creditors included Groom, Daniel, & Co., 30*l.* 18*s.* 9*d.*; D. W. Green, Colchester, 25*l.* 17*s.* 9*d.*; G. Houghton & Son, 18*l.* 7*s.* 5*d.*; Photographic Supply Company, 16*l.* 7*s.* 6*d.*; O. Sichel & Co., 79*l.* 19*s.* 9*d.*; and F. M. Wallis, Halstead, 24*l.* 4*s.* The Official Receiver's observations were to the effect that the debtor was for some time manager of a boot manufacturer in Colchester, but that in 1894, having a free capital of about 40*l.* in money, together with some furniture, he started business as a photographer, but traded under the style of "T. & E. Morter," those being the initials of two of his sons, to whom in time he hoped to transfer the business, but neither of them ever were partners in the concern, and neither of the two are yet of age. He states there is great competition in the photographic business, and that he has been obliged to do what work he has done at prices that were not remunerative. Practically the whole of the assets are said to be covered by a bill of sale, and a sum of 7*l.* 10*s.* accrued due of March 25 for rent. The trustee in bankruptcy will probably have a better title than the bill-of-sale holder to the more valuable part of the goods on the premises. The creditors fully secured hold a life policy for 50*l.*, which has been in force about seven years, and on which 10*l.* has been paid. The creditors returned as partly secured are the Bedfordshire Loan Company, 68*l.* 10*s.*, and the landlord for 7*l.* 10*s.*, and the security held is a bill of sale on photographic apparatus, studio, and furniture, which the debtor estimates to be worth 57*l.* With regard to the bill-of-sale holders, the debtor states he has received from them in all 67*l.* in two separate amounts, and that he has repaid 59*l.* on account of it, and now owes about 70*l.* The only book of accounts kept by the bankrupt is one which is a record of goods sold on credit, consequently the books do not show when the debtor first became aware of his insolvency, but he admits he has known it for several years, during which time he has contracted some small debts. The debtor attributed his deficiency to bad trade, heavy interest on borrowed money, legal expenses, and bad debts, but at present he has furnished no details. Mr. Ashor Prior appeared for the debtor. In reply to the Official Receiver, the bankrupt stated that his household furniture and photographic apparatus was entirely covered by a bill of sale held by the Bedfordshire Loan Company, being, in addition, subject to a distress for rent by the landlord, who had that morning put the billiffs in possession. Asked as to the circumstances under which he gave the bill of sale to the Bedfordshire Loan Company, the debtor said that at the outset he borrowed 33*l.* or 34*l.* from the Company on a note of hand, and signed for 50*l.* This transaction took place in 1896. In connexion with the note of hand, he repaid 15*l.*, and, as he was unable to meet the next instalment, the Company issued a writ, and the only course open to him was to give a bill of sale on his furniture and effects. The Official Receiver: Did you receive any further money then? Debtor: I received 33*l.*, I believe. There was 75*l.* handed to me in cheques, but I had to return all but 33*l.* The Registrar: This is the form, I suppose. Yes, it goes in one hand and out of the other. The Official Receiver: That was a bogus transaction, then, with the exception of the 33*l.* you received. Debtor replied in the affirmative, and, continuing, said he had had from the Bedford Loan Company about 67*l.* in all, and of that sum he had repaid 59*l.* Some time ago Mr. Isaacs, the manager of the Loan Company, had complained to him in reference to his irregular payments, and informed him that debtor then stood

in the same position as before, and still owed 75*l.* When employed by Mr. John Kavanagh as manager of the boot manufactory, he was in receipt of a salary of 3*l.* per week, and relinquished the position on account of the fact that he was uncertain as to when his appointment might terminate. He attributed his present position to bad trade, the heavy interest he had paid on the loan, and the fact that he had lost three months' trade in removing from one shop to another. Replying to Mr. H. W. Jones, a creditor, the debtor admitted that he had kept no account books or any statement of receipts and expenditure. Mr. Jones observed that debtor was entitled to sympathy, but, at the same time, was very much to be condemned for going to such people as these money-lenders. The bankrupt said he had repaid 59*l.*, and still owed 75*l.* Mr. Jones (with emphasis): "Sharks!" The examination was adjourned until May 16.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
15.....	Borough Polytechnic.....	Excursion: Loughton and High Beech. Leader, E. G. Hawgood.
17.....	Bradford Photo. Society.....	From <i>Canterbury</i> to <i>Canterbury</i> . Dr. Llewellyn Morgan
17.....	Camera Club.....	Demonstration Evening: Photographic and Mechanical.
17.....	Richmond.....	Print Competition.
18.....	Birmingham Photo. Society ..	Exhibition of Mezzotint Engravings produced from 1760 to 1800, by eminent Engravers, from works by leading Artists of the Period. Kindy lent by E. Haines, M.A.
18.....	Hackney.....	<i>Our Swiss Trip</i> . L. S. Wilks, F. E. Roope, J. J. Westcott, and W. Fenton-Jones.
18.....	Iale of Thanet.....	Lecture: <i>Practical Points in Exposure, Development, and Printing</i> .
18.....	Lewisham.....	Lenses. M. Stodart.
18.....	Royal Photographic Society ..	Photo-mechanical Meeting: Apparatus for Half tone Process Work.
19.....	Borough Polytechnic.....	Flower Photography. H. T. Malby, F.R.P.S.
19.....	Leeds Camera Club.....	Demonstration: Stereoscopic Transparencies. C. Grayson.
19.....	Photographic Club.....	Slides: Gloucester Cathedral. F. H. Evans.
19.....	Southsea.....	Faults and Blemishes and their Causes. Development. Mr. Fmiler.
19.....	Woodford.....	<i>The Colony of Lagos</i> . Hon. Thomas E. Rayner, Chief Justice.
20.....	Camera Club.....	Enlarging Evening.
20.....	Darwen.....	Lantern Night: <i>Stockholm, &amp;c.</i> L. Medland.— <i>South Africa</i> . Mr. Pritchard.
20.....	London and Provincial.....	<i>A Holiday in Venice</i> . E. D. Purcell.
20.....	Putney.....	<i>The Record Survey of England</i> . Mr. Scamell.
21.....	Oroydon Microscopical.....	

### ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 11.—Ordinary Meeting.—The Right Hon. the Earl of Crawford, K.T. (President), in the chair.

#### NEW MEMBERS.

Six new members were elected, and two candidates for membership were nominated.

#### THE EXHIBITION.

The PRESIDENT announced that the Council had appointed the Selecting and Hanging Committee for the forthcoming Exhibition as follows:—Pictorial: Messrs. Vivian Hyde, J. A. Hodges, J. B. B. Wellington, R. Child Bayley, A. Mackie, and J. C. S. Mummery. Technical and Scientific: Messrs. Chapman Jones, F. A. Bridge, E. J. Wall, J. J. Vezey, T. Bolas, and Captain W. de W. Abney.

#### EXPOSURES IN CORONA PHOTOGRAPHY.

Mr. E. WALTER MAUNDER, F.R.A.S., read a paper on "The Correct Exposures to be given to Photographs of the Corona," in which he discussed the question—Given a total eclipse of the sun, the sky clear, the sun high, what exposure or exposures should be given in order to secure a complete record of the different details of the corona? The solar prominences and chromosphere, the inner and outer corona, and the coronal rays, differ so enormously in brightness, that the problem at first sight appeared impossible of solution, except by the method of giving a great variety of exposures to different plates, with the certainty that no one plate would satisfactorily show more than one or two of these regions. At the last eclipse the only observer who did not proceed on this principle was Professor Burchhalter, who devised an ingenious plate-holder which gave an exposure to the outer coronal regions fifty times greater than that which the inner received, and the degree of success which he attained rendered it more imperative than ever that the best exposure for each different region should, if possible, be ascertained. The exposures employed during the late total solar eclipse varied in equivalent duration from 1 to 7200, and three series of photographs placed at Mr. Maunder's disposal—slides from which were shown—gave together a range of equivalent durations from 1 to 1800, and were all taken with very small apparatus, the apertures varying from  $\frac{1}{16}$  inches to  $\frac{1}{4}$  inches, and the *f*-a being respectively 57, 143, and 6. A comparison of these photographs appeared to show that, with *f*-15 and an extra-rapid plate,  $\frac{1}{16}$  of a second to  $\frac{1}{4}$  of a second was ample for the prominences; while for the inner corona  $\frac{1}{16}$  to  $\frac{1}{4}$  was sufficient, the amount of the corona photographed increasing rapidly until the exposure reached about half a second. Beyond this point the prolongation of the expo-

sure was of little advantage; and in a clear sky, with a high sun, one second might be taken as practically the limit of a serviceable exposure with  $f$ -15 and the most rapid plates. The extensions or streamers, however, were much fainter than the corona proper, and a considerably longer exposure was necessary to secure them, as long as 100 seconds or more being required, intermediate exposures tending only to spoil the photographs of the corona proper without securing any extension worthy the name. These prolonged exposures raised special difficulties, owing to the proximity of the long, faint streamers to the overpowering brilliancy of the corona itself, and the author attributed the success which Mr. Maunders achieved in this direction to the employment of triply coated plates. He thought the superior limit of exposure for the streamers had not yet been reached, his opinion being based on the fact that nearly two minutes after totality a plate was exposed for one and a half seconds (equivalent to about nine seconds with  $f$ -15), which showed the inner corona entirely round the dark disc of the moon, close to the reversed and solarised image of the emerging sun, the first time that the corona had been unmistakably photographed in so much sunlight. He thought that, except for particular purposes, the corona could be perfectly well photographed with most cameras by a snap-shot; and the camera should be pointed directly to the eclipse, and be firmly fixed, and if the aperture did not exceed  $f$ -15 or  $f$ -20, and the image of the sun did not exceed an inch in diameter, an equatorial stand or a driving clock was not necessary.

Captain HILLS, R.E., congratulated Mrs. Maunders upon her "record" photograph, showing streamers extending five and a half times the sun's diameter, and alluded to the importance of considering the weather conditions at the moment of totality, and of keeping one's head so as to properly adjust the exposures in accordance with those conditions. He showed some prints from Kodak negatives (of course, very small) in which the corona was clearly depicted.

The Rev. F. C. LAMBERT asked whether the speeds of the different plates used had been taken into consideration in tabulating the exposures and the results, and he suggested the possibility of making composite prints from a series of negatives showing various phases of an eclipse.

Mr. SEBASTIAN DAVIS referred to the question of the influence of the developer upon the result, some developers giving brilliancy, while others gave detail, and also to the importance, in such delicate work, of testing the plates by immersing an unexposed plate in the developer, and noting whether any effect was produced solely by the action of the developer, and without the access of light.

Dr. LINDSAY JOHNSON suggested that the use of suitable colour screens might tend to render detail which could not otherwise be secured.

The PRESIDENT mentioned some of his own experiences when photographing the eclipse of 1870 at Cadiz, when he used a reflecting telescope of 12 $\frac{1}{2}$  inches aperture and about 7 feet focus, the exposure with wet plates being, of course, very much longer than was now necessary. The great difficulty arose from the light in the sky, which was so considerable that he had never been able to believe the time-honoured story that chickens went to roost during an eclipse, under the mistaken impression that bedtime had arrived.

Mr. MAUNDERS, in acknowledging the hearty thanks of the Society, said the speeds of the plates had been taken into consideration in reducing the exposures to a common factor, as also had the developers, and plates had been tested before developing the negatives, as suggested by Mr. Davis.

#### SHUTTER SPEEDS.

Dr. LINDSAY JOHNSON described an instrument, which he presented to the Society, for testing the speed of shutters without taking a photograph. It appeared to consist of a clockwork arrangement, by means of which a diaphragm, pierced with a number of equidistant apertures, was rotated, and the speed of a shutter was ascertained by counting the apertures visible between its opening and closing.

#### COMING EVENTS.

April 18, Photo-mechanical Meeting. Exhibition of Apparatus for Half tone Process Work. April 25, Technical Meeting. A demonstration of the making of glass diaphragms, from "thin" to Newton's "very black" stage, by Mr. Thomas Bolas, F.I.C., F.C.S.

#### PHOTOGRAPHIC CLUB.

APRIL 5.—Mr. A. Mackie in the chair.

Mr. E. W. Foxlee handed round some stereoscopic glass positives, made about forty years ago, and condemned at the time as not of saleable quality. It was interesting to have an authentic case like this, where one could see what sort of standard photographers set themselves, the examples shown being of such a quality which would probably not, in these days, preclude their ready sale.

There was some discussion regarding the ozotype process of Mr. T. Manly for carbon printing. In this process, it will be remembered, the image is printed upon what is practically the transfer paper, and this fact led to the recall of the details of a method described by M. Marion, in 1873, before the Photographic Society of London. "Mariotype by contact," as it was called, was akin to Mr. Manly's process, although not so much as to be confused or regarded as one. M. Marion printed his negative upon a piece of sensitised transfer paper instead of upon the sensitised pigmented tissue, thus allowing printing to be observed as in silver and other processes. The image is of a pale brown tint, without vigour. The print is then immersed with carbon tissue of the desired tint in a bath of bichromate of two per cent. strength, the two are brought into contact, and squeezed. The similarity in result, if not in action, between Mr. Manly's and M. Marion's process is here apparent. The printed image on the transfer paper in both cases effects a change upon the pigmented gelatine tissue such as light would have exerted in the usual way. Marion's process required that the squeezed print and tissue should remain some ten hours between blotting-paper under a weight, after which development is effected in warm water.

**Borough Polytechnic Photographic Society.**—This Society opened their outdoor season on Easter Monday with a successful trip to Ely Cathedral, under the leadership of Mr. H. S. Kemble. A goodly number of members turned out, and, through the courtesy of the Cathedral authorities, very little difficulty was experienced with holiday visitors. Ideal weather prevailed, and altogether a most profitable day's work was accomplished. A substantial tea was afterwards served in good style at the City Temperance Hotel, the well-known rendezvous of all photographic visitors to the Cathedral. The privilege granted by the Great Eastern Railway for the party to travel in reserved compartments on excursion trains was greatly appreciated, particularly on the return journey. The Borough Polytechnic Photographic Society are moving strong in the matter of outings this season, and some good and useful trips are promised. A detailed programme can be obtained of the Excursion Secretary, Mr. P. C. Cornford, at 105, Borough-road, S.E.

#### Redhill and District Camera Club.—

#### DRY-PLATE PROCESSES AND MODERN DEVELOPERS

was the title of a most interesting lecture given by Mr. WILLIAM BROOKS at the fortnightly meeting of this Club on Tuesday, April 4. Mr. Brooks began his lecture with a brief reference to the first attempts at dry-plate processes carried out during the early part of the present century. The albumen and morphia processes were then described, and negatives on plates coated with these emulsions were shown. The gum-gallic process was next referred to, and a negative taken in 1869 shown. Mr. Brooks then gave a practical demonstration in the preparation of collodion dry plates, showing how the emulsion was prepared and the plate sensitised. Drawing attention to the importance of only using the finest and best cotton in preparing collodion emulsion, Mr. Brooks said that an ideal cotton was very difficult to obtain, as that sold by the chemists was practically useless. Several fine collodion negatives were then handed round, the clearness and depth of the shadows to be obtained by this process being pointed to. After some remarks on the gelatine dry plate, Mr. Brooks gave a *résumé* of the principal modern developers, amidol and glycin ranking first in his opinion. He had also a word of warning to say about the use of metol, asserting that its use was attended not only with considerable risk of prolonged injury to the skin of the hands, but even to life.

#### FORTHCOMING EXHIBITION.

1899.

April 14–May 13..... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

## Patent News.

THE following applications for Patents were made between March 20 and April 1, 1899:—

BACKING DEVICE.—No. 5970. "An Improved Device for the Application of a Paste Backing or suchlike Composition to Photographic Plates." J. H. AVERY and C. VARNAM.

FABRIC PRINTING.—No. 6010. "Improvements in Photographic Print Fabrics." Complete specification. J. A. HARVEY.

PLATE-HOLDERS.—No. 6076. "Improvement in Plate-holders and Means of Attaching same to Camera." F. SHEW.

IMITATION PHOTOGRAPHY.—No. 6122. "A Method of producing Photographs in Imitation of Wax Seals and the like." C. S. JONES.

CINEMATOGRAPHY.—No. 6202. "Means for Taking and Exhibiting Cinematographic Pictures." F. M. LEE and E. R. TURNER.

CINEMATOGRAPHY.—No. 6327. "Improved Means and Apparatus for Exposing Photographic and like Views Cinematographically." L. E. GRANICH-STADTEN.

CINEMATOGRAPHY.—No. 6350. "An Improvement in Apparatus for Taking, Printing, and Exhibiting Photographs." A. WATKINS.

CAMERAS.—No. 6462. "Improvements connected with Photographic Cameras." F. W. SAXBY.

FOCUSSES.—No. 6560. "Connecting the Focussing Gear of a Process Camera with the Screen Gear thereof." O. LINLEY and T. W. LASCELLES.

ENLARGING CAMERAS.—No. 6588. "Improvements in or connected with Photograph Enlarging Cameras." A. STALINSKI.

SHUTTERS.—No. 6628. "Improvements in Photographic Shutters." J. E. THORNTON.

STORING PLATES AND FILMS.—No. 6629. "Improvements in the Mounting, Storing, and Manipulation of Sensitised Plates and Films." J. E. THORNTON.

CAMERAS.—No. 6639. "Improvements in or connected with Photographic Cameras, part of which Improvements are also applicable to Opera Glasses and the like." W. H. McCANDLISH.

LENS MOUNTS.—No. 6708. "Improvements in Mounts of Photographic Lenses." RATHENOWER, OPTISCHE INDUSTRIE-ANSTALT.

MAGAZINES.—No. 6705. "Improvements in Magazines for Photographic Plates." J. F. G. DE GEORFOY.

APPARATUS.—No. 6708. "Improvements in Photographic Apparatus." Complete specification. O. D. BINGER.

CHANGING BOX.—No. 6734. "Improvement in Photographic Camera and Changing Box for use with Sensitive Plates and Films, and Means of Protecting same when Exposed." W. C. WHITE.

**CAMERA FITTINGS.**—No. 6775. "Improvements in Fittings for Cameras." J. A. WILBY and W. L. TATTERSALL.

**STEREOSCOPIC PHOTOGRAPHS.**—No. 6794. "Improvements in Apparatus for taking Stereoscopic Photographs and for Exhibiting the same." Complete specification. W. K. L. DICKSON.

**INTENSIFYING PRINTS.**—No. 7021. "Improved Process for Intensifying Photographic Silver Prints." Communicated by Actiengesellschaft für Anilin Fabrikation, Germany. C. D. ABEL.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE GLOUCESTER CONVENTION.

To the Editors.

GENTLEMEN,—On Wednesday next, the 19th inst., a lecture will be delivered by Mr. F. H. Evans at the Photographic Club (Anderston's Hotel, Fleet-street, E.C.) which should be specially interesting to intending Conventioners.

The subject is "Gloucester Cathedral," and those who may have had the pleasure of hearing Mr. Evans and seeing his slides of similar subjects will not need to be assured of an enjoyable evening.

Mr. W. B. Stretton (4, Queen street-place, London, E.C.), the Hon. Secretary of the Club, will be pleased to send tickets to any who may apply for them, and visitors will be heartily welcomed by the members. —I am, yours, &c.,

F. A. BRIDGE, Hon. Secretary and Treasurer, P.C.U.K.  
East Lodge, Dulston-lane, London, N.E., April 8, 1899.

### ROLLABLE FILMS.

To the Editors.

GENTLEMEN,—The letters in your Correspondence columns re cheap rollable films recall a question which has interested me, and to which some readers of THE BRITISH JOURNAL OF PHOTOGRAPHY may have something to say. It is this: Why are there so many varieties of plates manufactured and practically only one rollable film? Is it because there is no demand for the article in question? Consider its advantages: (a) daylight changing, (b) any quantity can be carried without increasing the thickness of a folding camera, e.g., folding pocket Kodak, (c) without increasing the smallest possible rectangular dimensions of a box camera (e.g., bull's-eye Kodak), (d) the only detachable magazine (except the heavy and costly changing box), (e) it has rendered possible the cinematograph, (f) owing to the simplicity of the necessary apparatus, cameras are perfectly efficient and self-contained.\*

It is not too much to expect that long bands of rollable material must ultimately take the place of separate sheets in the manipulations of photography, just as has been the case in other branches of manufacture, e.g., paper-making and printing. The advantages are too obvious. The greatest objection that can be urged against rollable film is that it is not substantial enough, as Captain Abney puts it, it does not possess the ideal flatness of surface that the new lenses require for the best results. Much of this may be got rid of by careful construction of the holder. Our premier form of high-class hand-camera makers have adopted the roll-holder, so difficulties in that direction may be discounted. Then there is the objection that one cannot conveniently develop single pictures, which is certainly considerable, though not so great since the short spools for twelve exposures have become common. The difficulties of development are to be got over only by practice, just as any other difficulty in photography.

Your correspondents suggest the reintroduction of a stripping film. Such an article is very desirable, and, with the celluloid film at its present high price, should be commercially successful if supplied at a reasonable cost—not more than 9d. for the quarter-plate spool of twelve exposures. But, of course, what is really wanted is a cheap non-stripping film at a price not considerably above that of plates. Considering the much greater reduction that has taken place in their prices, this does not seem too much to hope for.

Moreover, why is it that we never hear of any alternative to celluloid, a basis about which so many complaints are made? Is it possible that the resources of the manufacturer can discover nothing else in this go-ahead age, or is it probable that, if photographers still made the most of their own material, as used to be the case, we would long be without a single rival to celluloid (excepting setcoid)? It is here that one deplores the lack of interest which amateurs and professionals alike take in all that concerns the fermentation of the sensitive films they use. To an extent unknown in any other branch of science, the knowledge of the many has become the knowledge of the few. How many, for instance,

\* May be made at a smaller cost than those to carry plates or cut films.

have any accurate idea of the means by which such an enormous increase in speed of sensitive emulsion has been obtained within the past few years, or can you get a text-book which even hints at the matter? Details of processes which used to be knowledge easily attainable to all are now guarded jealously by manufacturers as secrets it would be ruinous to divulge. The amateur experimenter, who used to be a power in the land, is now almost extinct, and the manufacturer can only experiment along lines which are likely to yield profitable results, leaving questions of merely scientific interest severely alone, a policy which, though necessary, is, on the face of it, opposed to the interests of all true progress.—I am, yours, &c., H. M.

### THE COLOUR OF RESIDUE INDICATING THE TEMPERATURE AT WHICH ACETYLENE IS GIVEN OFF.

To the Editors.

GENTLEMEN,—Your contributor, Mr. G. R. Baker, has noted and replied to my statement "that the black colour is not to be relied on as an indication of temperature, but rather as an indication of bad carbide," and has pointed out that it is Professor Vivian Lewes who is responsible for the statement I took exception to. Further, Mr. Baker has ventured an explanation as to why my black residues are not due to faulty carbide—is that the carbide has become coated with a tarry residue which protects it from the action of water. I reply, This is not the solution. I venture to still adhere to the opinion—in fact, more strongly express it—that the black colour is more often due to bad carbide than to overheating. This statement of Professor Vivian Lewes, if allowed to go unquestioned, might be used to cover up inferior carbide; and the admission of the truth of my statement is of importance to users of acetylene. That you, Mr. Editor, may form some opinion of the "tarry deposit" on my black residues, by same post I send you a sample of the black residues, which I hold indicates that bad carbide has been used.

Many statements have, of late, been current re acetylene—emanating mainly from those commercially interested in carbide or apparatus for, and such as must be estimated as "professionally fee-paid opinions," which, if not actual mis-statements, are pronouncedly misleading. One of these statements, freely circulated and often quoted, is that one cubic foot of acetylene is equal in value for lighting to sixteen cubic feet of ordinary town gas. I hold such a statement is barely true under the worst conditions of town gas and the best of acetylene; and that, if the ratio value were taken under average conditions, and with the present incandescent gas system, the truth would stand, one cubic foot acetylene equals two of town gas. A correspondent in the *English Mechanic* says that the cost of lighting by the two systems is "that acetylene costs twelve times that of town gas."

Acetylene is in many points a most desirable light, and much of its future is in the hands of the present makers of carbide of calcium; it is for the users to remove any misleading statements which might gain force if left unchallenged.—I am, yours, &c., VEDA.

### THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

To the Editors.

GENTLEMEN,—In answer to Mr. Rees' article in your JOURNAL of April 7, will you allow me to again state that such an Association as he sketches does already exist in the National Photographic Record Association, the object of which is to organize photographic survey work throughout the British Islands, and also to collect photographs of objects of interest—scenery, life customs, &c.—as may be of use to posterity as a record of our times, and to mount and deposit such prints in the British Museum for public reference. Up to date they have received some 600 prints including such subjects as suggested in Mr. Rees' letter.

The Council look for generous support from photographic and camera clubs throughout the country as well as from individual amateur photographers, many of whom must possess rich stores of old and neglected negatives taken in past years of buildings, &c., since destroyed and of which there is a possibility of all records being lost.

I shall be happy to forward particulars as to membership, class of photographs desired, &c., on application.—I am, yours, &c.,

21 Avenue-road, Highgate, London, N. GEORGE SCAMMELL, Hon. Sec.

### THE COOKE LENS AND THE T. T. & H. ADVERTISEMENTS.

To the Editors.

GENTLEMEN,—Your last issue but one contains a very interesting patent specification, wherein Mr. H. Dennis Taylor gives a description of certain improvements in the Cooke lens. After referring to the means by which certain lenses may be used at will for different focal lengths, Mr. Dennis Taylor proceeds with the statement that the Cooke lens cannot be used in such a manner, and that his present invention is "for the purpose of supplementing this deficiency in a sufficiently simple and effective manner."

I have watched with sardonic interest Messrs. Taylor, Taylor, & Hobson's altruism, as shown in their advertisements, and the following

specimen, published in a contemporary on May 13 last, acquires additional interest at the present moment:—

"There is a sort of knife, prized by schoolboys, which contains a saw, a toothpick, and a hammer. Older people know that, if they want a good knife and a good saw, they must buy them separately. It is the same with photographic lenses. There are some lenses which can be used in bits to form other makeshift lenses. Cooke lenses are not of this sort. Their glasses cannot be used separately. They are made for fine work, and are very accurately adjusted, and no lens which is frequently separated and rearranged can retain the requisite precision of adjustment which Cooke lenses always possess."

This advertisement was an attack on certain lenses, the components of which could be used separately or paired up with other lenses to form other combinations of different focal length. Yet within twelve months we find the Cooke lens is to be improved in a similar manner.

Will Messrs. Taylor, Taylor, & Hobson amend their advertisement, and proclaim, "There is a lens, prized by schoolboys, which contains," &c. &c.—I am, yours, &c.  
PHOTOGRAPHER.

### CINEMATOGRAPHING A MURDER.

To the Editors.

GENTLEMEN,—I notice in your issue of the 3rd ult. an article stating that cinematograph pictures were offered in evidence in the trial of a recent murder case in our Criminal Court.

The whole statement is in error. The murder of the late Mr. Baker took place in the street, not in a room, as stated. No cinematograph pictures were made or used. The only photographs were some taken by a local photographer, long after the murder, and intended to show to the jury, had they been admitted as evidence, some of the conditions under which the murder occurred.—I am, yours, &c.,  
2636, Osage-street, St. Louis, March 27, 1899. WILLIAM M. BUTLER.

### PHOTOGRAPHIC SOCIETIES THEN AND NOW.

To the Editors.

GENTLEMEN,—A very interesting and unique letter has been discovered by the President of the Leeds Photographic Society as to the procedure of the club in regard to obtaining the interest of its members in the very early stages of its career in the year 1853. As I thought you would perhaps like to print such a letter, I have taken the liberty of enclosing you same.

In view of the very lackadaisical way in which some societies go about their work, the letter is doubly interesting.—I am, yours, &c.,  
WALTER L. FIELDHOUSE.

40, Tempest-road, Beeston-hill, Leeds, April 7, 1899.

[COPY CIRCULAR.]

"The next meeting of the Leeds Photographic Society will be held on Thursday evening, September 8, at No. 4, Park-row, to commence at eight p.m., when a discussion will be opened by J. W. Ramsden on the action of bromine and the bromides."  
"Leeds, 8 month, 1853."

[COPY LETTER.]

"At the meeting held August 23, a by-law was passed to the effect that 'The business of the meeting be commenced punctually at a quarter past eight, that five shall form a quorum, and that, if at the time specified there be not five members present, there shall on no account be a meeting that evening.'

"It was further requested that the Secretary should impress upon the members the duty of regularly and punctually attending the meetings, through the neglect of which the Society was not doing the amount of good it ought to do.

"It was resolved that at our next meeting (September 8) each member be expected to bring up the title of a paper, and which he will volunteer to read at some meeting of the Society within six months. Any member prevented from attending is requested to send to the Secretary the title without fail before the day of the meeting. This arrangement would, it was thought, put the proceedings of the Society in a more regular train.

"Members are requested to come prepared to enter into the discussion on bromide, as the opening by J. W. Ramsden will be merely a formal one.

"H. B. BRADY, Hon. Secretary."

### THE TANQUERAY FREE PORTRAITS.

To the Editors.

GENTLEMEN,—A gentleman brought me a Tanqueray enlargement to frame for him; he received the circular (which by the way I have, and am likely to keep it), which promises to send an enlargement free of charge. I asked what it cost him, he told me they notified the picture was ready and recommended a frame which was an enormous price; he wrote them and said he was too poor to have such a frame, and after writing three or four times he got it eventually after being bound to send eight francs (6s. 8d.) to pay carriage, so it cost him 6s. 8d. without the letters he sent; asked what I thought of it, I told him it was just about worth what it had cost him and I added I would make him one equal to that for 10s. 6d. I fail to see where the four guineas' worth is.

I thought perhaps you would not mind me sending this note, as you were writing about it some little time ago.—I am, yours, &c.,  
North-street, Garshilton.  
F. HOLLOWAY.

[We are pleased at having the opportunity of publishing our correspondent's letter. The more light that is thrown on the business methods of Tanqueray the quicker will the time come when he and his congeners will find their occupation gone.—Eds.]

### THE FUTURE OF PHOTOGRAPHIC ASSISTANTS.

To the Editors.

GENTLEMEN,—Your leaderette in the JOURNAL *re* above question ought to do good both to master and workman. I am sure a better feeling ought to be shown between both than is done in a great many cases at the present time; but operators and retouchers bring a lot of it on their own shoulders, and, when you consider a lot of situations are got by fraud and false pretences, you cannot be surprised at the bad feeling that exists in the master's breast.

For example, four years ago I had occasion to engage an operator and retoucher (assistant). I wrote to one advertising in this JOURNAL, and asked him to send me specimens of his work. To my astonishment, three out of four were taken by us in our studio here. I wrote him and told him unless he could give me particulars how he got the specimens I would expose him in the JOURNAL. He explained how, and I found they were printed and sent out by one of our assistants. However, I engaged the man, and have had no room to regret it. About twelve months since, I was short of another hand, and advertised in our local papers, had an applicant, asked for specimens, and this time had six sent, but three were the same as our operator was engaged on. I asked him (the operator) if he could explain how this man could get hold of the same specimens, and he said no doubt some of the assistants had printed and sold them, as is frequently done. I went to Leeds to see the applicant, and found out that he was only an amateur.

I don't like this sending specimens, and if photographers would drop their jealousies, and when we had an applicant for a situation, could ask such a one to call at so-and-so studio and retouch a negative and do a couple of prints, we should know who we were engaging, and worthy men would get good situations. But, until something is done, masters and workmen suffer, and masters often are paying a good salary for an operator or retoucher to learn their business.

I am sure both men and masters will be thankful to you for ventilating a question that has given a lot of trouble to all concerned. Thanking you in anticipation,—I am, yours, &c.,  
HENSTEPS.

To the Editors.

GENTLEMEN,—I have read with interest the many letters appearing in THE BRITISH JOURNAL OF PHOTOGRAPHY setting forth the troubles of photographic assistants.

He will be a clever man indeed that successfully launches a "Photo Assistants' Union."

How many have availed themselves of the Shop Assistants' Union? Where is the Benevolent Society?

The average photo assistant's idea of providing for a rainy day is well known to those who work amongst them.

How many assistants buy the ALMANAC or the JOURNAL when they are in employment? Not one in ten, consequently they are all behind in anything new that comes to light.

Now, Mr. Editor, there is a chance to remedy one evil.

Why should not a fixed quarterly subscription, entitle a subscriber to receive by post THE BRITISH JOURNAL every week, the ALMANAC, and to advertise free in the "Situations Wanted" when he is out of employment.

A stern rule that subscribers only shall have the privilege of advertising for a situation in your paper would force enlightenment in the way of many, and would, I think, be the first step to better times.—I am, yours, &c.,  
ASSISTANT.

[Many other letters to the same purport as the foregoing have also reached us, but, as their contents are mainly repetitions of what has already been said on the subject, it is not necessary to publish them. The correspondence has revealed a state of things in the photographic labour market for which it is difficult, if not impossible, to suggest a remedy. If aggrieved assistants will not combine for the purposes of self-help and mutual protection, it is hopeless to expect that any material improvement in their general condition will take place; and, even were such a combination formed, it is very doubtful, in the peculiar circumstances of the case, whether a satisfactory solution of the problem would be reached. The simplicity of modern photography is responsible for flooding the photographic labour market with an overwhelming amount of mediocre ability which we fear is usually remunerated in the exact ratio of its value. On the other hand, we are convinced that in photography, as in every other pursuit, the law holds good that talent is bound to assert itself in the long run.—Eds.]

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

H. C. Mosser, 29, Castle-street, Salisbury.—Cabinet photograph of L. E. Pyke, Esq., Q.C.

A. Glass, 79, St. Leonard's-road, Windsor.—Photograph of 2nd Life Guards returning from church, Easter, 1899.

F. Coghlan, 31, Carlisle-road, Londonderry.—Photograph of the Very Rev. Charles McPaul, P.P., Londonderry.

A. McHarris, County Studio, Stranraer.—Photograph of casket given to the Right Hon. John Hamilton Dalrymple.

The Globe Photographic Company, 29, High-street, Southampton.—Two photographs of Captain Reeks: 1. standing position; 2. sitting position.

IN OUR NEXT.—A. G. FIELD, &c.

VICTOR SELB (Anvers).—Imperial Mills, Hereford, is the address.

GUINEA TOUCH.—We cannot trace, but believe it is Messrs. Butcher's, Blackheath, S.E.

ANXIOUS.—The prints are moderately good specimens of portraiture, and they show promise of better things.

LENS.—We do not know the first-named series. A lens of the modern anastigmat type would be preferable.

D. BACHRACH (BALTIMORE).—We are much obliged to you for your interesting letter, to which we may refer on a future occasion.

LANCASTRIAN.—1. Great Windmill-street, London, W. 2. Rue Louis-le-Grand, Paris. 3. It will answer all your requirements.

HANS DANZER.—We should recommend you not to come to England, as the market is overstocked with labour of the kind you mention.

F. Y.; A. F.; TWENTY-THREE SHILLINGS A WEEK; AND OTHERS.—Many thanks for your communications; but, as you will see by a note on the previous page, we have closed the correspondence.

ADDRESS WANTED.—ANTIPODES inquires: "Could you give publisher's address of *The Australian Photographic Journal*?"—In reply, the address is 66, King-street, Sydney, New South Wales.

PRINTER.—1. With regard to the platinum (developing) bath, you had better follow the Company's instructions. They are exceedingly simple. 2. See the formulae for albumen toning baths in our ALMANAC for 1899.

COLLOIDIO.—You can only decide such a point for yourself by practical trial. There are several brands advertised in our ALMANAC. Personally we have found both home and foreign makes to fulfil your requirements; but it is against our rules to make the kind of recommendation you ask for.

HEINRICH'S GELATINE.—A. BAKER says: "Will you kindly give me the address of the agent in England for Heinrich's gelatine, also the foreign address?"—Messrs. Zimmermann, St. Mary-at-Hill, E.C., are, we believe, the English agents. The gelatine is made in Germany, and is only supplied here through the agents.

CHRISTOPHER.—It is against our rules to make recommendations such as you invite. Procure a copy of *THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC* for 1899, in which most modern instruments are described with sufficient fulness to enable you to come to a decision as to the best way of satisfying your requirements.

PORTRAITURE.—Perhaps your best plan will be to peruse Mr. Robinson's *The Studio*, and what to do in it. It is published, we believe, by Sampson Low & Co., St. Dunstan's House, Fetter-lane, E.C. As to a book on the "art of developing," we should recommend you to follow the instructions given with the brand of plates you use. Do that successfully, and you will not require any books on the subject.

STUDIO WALLS.—N. B. says: "Could you suggest anything to cover the sides of a studio? It is a slim erection (wooden), being meant for the summer season only. What I wish is something inexpensive that could be taken down at end of season. Paper or paint would be unsuitable, as the boards are rather rough, and open in some places."—We should suggest "match-boarding" the inside, or, next to that, canvassing and papering the walls. Either would be tolerably inexpensive.

MONCKHOVEN'S INTENSIFIER.—G. H. FORD says: "Re formula for Monckhoven's intensifier on p. 1049 of *THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC*, will you kindly let me know in your Answers to Correspondents, 1. for how many quarter-plate negatives the quantity given will do? 2. and how long the negative should be left in the B solution? 3. Also if the negatives require to be washed before they are put into the A solution?"—1. We cannot say, as we have never tried. By the way, two quantities of the solutions are given. The English measure is for one ounce the French for a litre (about thirty-five and a half ounces). 2. Until the desired density is obtained. 3. Yes, thoroughly washed, and thoroughly fixed before washing.

FERROTYPE DRY PLATES.—BAZAAR. Ferrotypes dry plates, ready for use, are supplied by Fallowfield. Magnesium powder and flash lamps are also supplied by the same house. With a little practice beforehand, you ought to succeed.

AVOIDANCE OF DISTORTION.—CYCLER says: "Would you be so kind as to give me information as to the following: Can I use a short-focus lens, as Zeiss, Series III., nine-and-a-half inch focus (8½ x 6½ it covers) to photograph bicycles whole-plate without distortion? I am rather afraid the wheels will look elliptical."—The lens will not give distortion. If it is, however, brought very close to the subject, the perspective will, of course, be violent and unpleasant, as, indeed, is the case with any lens, whatever its form.

BOOK ON SOLAR ENLARGEMENTS.—GABRIEL MOULIN says: "Will you give me some information where I can get a book on solar enlargements, or developed enlarged prints other than bromides?"—We know of no work dealing with the subject. Monckhoven's *Optics* is the best work on the solar camera. It was published by Hardwicke, Piccadilly, but we suspect it is now out of print. It, however, gives no information as to the preparation and manipulation of the paper. In this country bromide paper has quite superseded the old iodised paper.

CRYSTOLEUM PAINTING.—S. E. YORKE says: "Would you please answer me the following questions: 1. What paper would I require to make prints for crystoleum painting? 2. What toning bath? I have had several asking me to make them prints for the above work, and I cannot get the paper thin enough."—In reply: 1. Ordinary albumen paper is what is generally used. The back of the paper is usually, to a great extent, rubbed away with glass paper after the print is mounted on the glass. 2. The ordinary acetate toning bath is as good as any, but others will answer.

PROTECTING PLATINUM PRINTS.—A. M. says: "I have to supply six prints for panels in trade cart. Platinotype process would be used. Can you suggest any form for covering prints to keep from rain or splashes? Glass will not do because of jolting. Would mica 'glass' do, and where could it be procured?"—We doubt very much if mica sufficiently large for the purpose, and transparent enough, can be had any where. We should suggest transparent celluloid; or, perhaps, the prints mounted direct on the panels of the cart, and then varnished with pale copal varnish, or French-polished with white polish.

PITCH OF STUDIO ROOF.—REX says: "I shall be obliged if you will inform me what you think a proper pitch for roof of studio, width of same being twelve feet, and to be erected in open garden, north light available, and no buildings on south side. I have been advised to adopt what is called a third pitch, leaving only about five feet on opaque side of roof. Do you think I should be inconvenienced by mid-day sun by so doing?"—Yes, that will do very well. Some sun will get into the studio during the midsummer months, but that can easily be dealt with by blinds. It is only about the middle of the day that the sun will cause any trouble.

ALBUMEN PAPER.—ALBUMEN says: "Will you please answer me, through the medium of your paper, the following questions: 1. How is paper albumenised? 2. How is the above sensitised, and also the bath for sensitising? 3. Where can I buy paper albumenised, but not sensitised, in small quantities? 4. The name of a good book on the above subject. 5. Will the paper keep when albumenised but not sensitised?"—1. Simply float the paper on the albumen. 2. By floating the paper on the silver solution for from two to three minutes; 45 to 60 grains of nitrate of silver to each ounce of water, according to the amount of chloride in the albumen. 3. At Marion's, or any of the photographic warehouses. 4. There is no work devoted to the albumenising of paper, but all the old works, such as Hardwich's, &c., give formulae. 5. Yes, if kept dry.

COPYRIGHT; ALTERING THE FOCUS OF A LENS.—MOZAIC says: "I am about to make up a mosaic group (bush). Suppose I copyright the mosaic print, would that copyright cover the copyright of each separate figure in the group? I mean, suppose any one used a portrait of one individual in the group, could I proceed against him for infringement of copyright? I have an old cabinet portrait lens by Lerebours. I had a stop which slid in front of lens, but I thought I would improve it by making a slit-in tube, and putting diaphragms the same way as the modern portrait lenses, but it does not seem to give the same definition. Have I done wrong?"—We are doubtful if it will. We have a vague idea of a case some time ago in which, in a somewhat similar picture, it was ruled that it did not. Better make each individual portrait copyright. The stops of the lens are now in a better position than they were at first. If you use the lens with the same size stop in the centre as the one that was in the front, we think you will get equal, if not better, definition.

MARKINGS ON LENS.—H. J. M. says: "Will you kindly give me an answer in your Answers to correspondents column to the following difficulty? The lens which I have had many years has lately shown (round the edges of the glasses) flower-like markings, almost transparent, as if the cement between the combinations were crystallising, and the marking appears to be spreading. The lens is very useful to me for other than the Frena, and I should like to know what I can do to remedy it without having, unless absolutely necessary, to send it to the makers for remounting. I had thought of wrapping it up in cotton-wool and carefully warming in the kitchen oven. Do you think this is likely to succeed? What, in your opinion, would be the effect on the definition of the lens of this marking? Have you ever come across a case like this before?"—Evidently the balsam has given way. We should advise the lens being sent to the maker to be re-cemented rather than tampering with it at home. No doubt, the performance of the lens is impaired in its present condition.

## EX CATHEDRA

IN these days of widely diffused knowledge regarding the minutest working details of photographic processes, it will probably strike the readers of this JOURNAL as anachronistic, if not incongruous, to be told that in the year of grace one thousand eight hundred and ninety nine albumen silver printing paper supplies the secret formula-mongers with the opportunity of plying a trade which, however it be examined, cannot easily escape a somewhat curious reputation. Yet such is the case. One way and another the secret formula-mongers have boxed the photographic compass, so to speak. They have traded in "secret" toning, developing, intensifying solutions, silver stain removers, emulsion formulæ galore, mountants, and so forth, culled in the majority of cases from the photographic papers. As a rule the formulæ are good and practicable, but occasionally we have come across instances in which a total lack of knowledge of the subject has been employed to attempt a downright swindle. Witness the case of the wily foreigner who, a year or two back, travelled the country with a rubbishy orthochromatising mixture, which he palmed off on many an unsuspecting photographer at half a guinea a bottle.

BUT all these things make an exclusive appeal only to the photographic as distinguished from the general public, to whom the secret albumen formula has long been persistently and, no doubt, profitably offered. The selection of albumen paper as a bait for the very large class which daily strains its eyes over the advertisement columns of the morning papers on the lookout for easy ways and means of adding to their incomes, is simply a master-stroke of genius. To speculatively inclined people, with a few pounds to spare and no inside knowledge of photography, how easy it is for the formula-mongers to dilate upon the ridiculously simple manner in which the paper is prepared, how cheap the materials, how gentlemanlike or ladylike—very often ladylike—is the occupation; what a valuable part of the secret is the preservative; what a large demand there is for the paper; how readily the editors of the photographic papers will give it a "lift up," and so on and so on. Cannot the reader see through the whole game as it is played off by the formula-mongers on the innocent widow or the gulleless clerk with that fatal "little bit of money" which she or he is laudably anxious to put out to profitable use?

\* \* \*

IF the reader will turn to p. 1048 of our ALMANAC for 1899, he will find a formula given, after mention of the usual silver bath, for a preservative, citric acid, to wit. This is substantially the secret formula which has long been on offer through the medium of an anonymous advertisement in the daily newspapers. To our knowledge, as much as 20*l.* and 25*l.* has been paid for it, plus working details, which can be found in half a score of text-books selling for from 6*d.* to 5*s.* each. Within the last year or so we have come across no less than four purchasers of this formula, all imbued with the ambition to supply photographers with sensitised albumenised paper. In the last five or six years we have received, we were going to say, scores, but certainly dozens, of samples of sensitised albumenised paper, the accompanying literature of which bore a strange and almost fatal resemblance to the very latest circulars that have reached us. Not one of these closely related brands remains upon the market to-day.

\* \* \*

THE hardest case of all that came to our notice was that of a widow lady, who, having spent the whole of her savings—

nearly 200%.—in an energetic attempt to persuade photographers to use her paper, reluctantly took our advice and discontinued an entirely hopeless business. The poor woman learned with surprise that she was one of many purchasers of the formula, that albumen paper had been an article of commerce for thirty or forty years, that the market was already well supplied with it, and that the probability of a profitable business being done in the paper was about as remote as the planets. We wonder how some thousands of our professional readers will receive the interesting intelligence that the majority of the many new and "best" brands of sensitised albumenised papers, samples of which have been sent gratuitously to them during the past five or six years, all have their origin in a common source—a familiar formula sold by means of an anonymous advertisement in a daily newspaper?

\* \* \*

RECENTLY all the documents relating to the method of business adopted by one vendor of a "secret" albumen paper formula have been placed in our hands. With the following sentence taken from a letter to a purchaser we, of course, were highly amused: "I should advise you not to let the editors of any of the photographic books know that you have only just been taught the business, and don't mention from whom you got your knowledge. Let them think you are thoroughly practical." We, for our part, think many things about this highly expeditious process of turning out "thoroughly practical" manufacturers of sensitive albumenised paper. For the present we withhold publication of these documents. They do not strike us as containing anything to which legal objection could be taken, although some of the statements that are made would not bear analysis. The practical instructions and working details have, of course, been published over and over again; but, notwithstanding this, they would not be dear at the price charged if the knowledge so vended were confined to one or two purchasers. This, however, does not appear to be the case. A great deal of albumenised paper is still used, and will continue to be used. But it cannot be gainsaid that the market is thoroughly well supplied with recognised brands of the paper. We are strongly of opinion that the introduction of numerous small makers, recruited from the readers of daily papers, who have no knowledge whatever of the conditions of photographic business, can only result in their finding out, sooner or later, that they have burnt their fingers in attempting to make money out of a thoroughly well-exploited printing process which, in these times, those having large capital and the keenest enterprise could only take up with the greatest possible risk.

\* \* \*

THE late Mr. Gleeson White, the accomplished writer on art subjects, was known to have much sympathy with photography in its pictorial and decorative aspects, and in recent years his kindly used critical powers were often called into service at some of the London photographic exhibitions and on other occasions. There is no doubt that, had he lived, photography would have found in him a constant and discriminating guide to the possibilities that lay before it. We are asked to draw attention to the fact that Mr. Gleeson White's unexpected death on October 19, at the early age of forty-six, precluded the making of any adequate provision for his wife and two children, and that, at a meeting of his friends

recently held, it was decided that a fund should be raised and applied for the benefit of his family. A committee of prominent artists has been formed for the purpose, and a first list of subscriptions has been printed. There may be some of our readers who would like to contribute to the fund, and we should be very happy to receive subscriptions on its behalf, or they may, if preferred, be forwarded to the Hon. Treasurer, Mr. H. R. Hope-Pinker, 22, Avonmore-road, West Kensington, W.

\* \* \*

MR. P. R. SALMON sends us from Nice the following interesting note as to the difficulty of obtaining photographs of the Queen: "I am staying here for about a week or so for the purpose of making a series of pictures illustrating Her Majesty's life here, and I must confess it to be a hard matter, as all the authorities are so dead against photographers. The Queen always wears a thick black veil, which is another great drawback, and one might almost as well photograph a bundle of black clothes. I have made many exposures, but nothing very satisfactory. On Sunday I counted thirty hand cameras outside the hotel; yesterday there were only nine. Mr. A. L. Henderson and I worked side by side yesterday, and afterwards I went with him to tea. He seems to have a pass everywhere, and walks past the sentries, whilst I am always stopped. Mr. Henderson and I, as far as I could see, were the only stereo workers." The mighty "A. L. H." may be envied for the splendid photographic opportunities he alone seems able to secure at Nice.

\* \* \*

WE have received the preliminary prospectus of the *Camera Obscura*, an illustrated international monthly magazine of photography to be published in four languages. The Editor-in-chief is to be Herr J. R. A. Schouten, and his colleagues are to be Maurice Bucquet (French Editor), R. Ed. Liesegang (German), Max Sterling (English), and Chr. J. Schuner (Dutch). Three of the foregoing names are by no means well known in the world of photographic journalism. The *Camera Obscura* is to be published in Amsterdam by Messrs. Binger Bros., and in London by Messrs. Williams & Norgate, 14, Henrietta-street, Covent Garden. The first number will be ready in June next. The magazine is to be illustrated, and, according to the prospectus which has been sent us, its pages will be filled with a great deal of interesting matter.

\* \* \*

A FEW years ago we had the opportunity of congratulating Mr. H. A. Chapman, the well-known photographer, of 235, High-street, Swansea, on his election to the honourable position of Mayor of that important town. We now learn that Mr. Chapman has recently been placed on the Commission of the Peace for the borough. We so seldom come across cases in which professional photographers are singled out for compliments of this nature that we are sure Mr. Chapman's professional brethren throughout the country will learn with satisfaction of the distinction that has been conferred upon one of their number. It is worthy of note, however, that although we rarely come across the name of a photographer associated with public offices, the very highest civic position in the world was once occupied by a photographer. We allude to the late Mr. George Swan Nottage, of the London Stereoscopic Company, who, some thirteen years ago, was Lord Mayor of London.

## CELLULOID VARNISHES.

THE question is very often asked as to whether there is any practical advantage in using acetone and similar solvents in making celluloid varnish over the frequently more easily available methylated spirit and ether; or, in other words, are the commercial slow-drying, and frequently evil-smelling, products, and those made by dissolving up old celluloid films equal? In answering the question, it is necessary to look at it from different points of view, and to consider whether what is required is a robust and perfectly impervious film, or whether one that presents a certain degree of porosity may not be permissible.

Taking the whole range of vehicles or solutions, from the standard commercial celluloid varnishes to ordinary collodion, suitable, we will say, for dry-plate work, we have a series of preparations presenting sufficient variety to satisfy the most fastidious, offering, as they do, every possible class of film from perfect impermeability to a beautifully even and porous condition not surpassed by the finest bibulous paper. With such a wide choice it is obviously possible, by judicious selection, to prepare a medium that will satisfy almost any requirements, and, at the same time, we do not think it would be very difficult to effect such a combination as will satisfy all the most stringent requirements of the photographer for negative-varnishing purposes. Primarily, the object of a negative varnish is to protect the negative, but, in effecting this purpose, very different conditions have to be considered.

In the very early days of paper and albumen negatives the necessity for varnishing did not make itself felt; but, on the introduction of collodion, the want became a crying one. But it was soon met by the introduction of simple spirit varnishes, or solutions of gum resins, amber, copal, and other substances in spirit, chloroform, or benzole, and for a long period the question of negative varnish was not one that gave much trouble. There were many of the old collodion hands, however, who objected to varnishing, and in comparatively recent years we have seen some of the earliest of collodion negatives, from which by no means insignificant numbers of prints had been produced, that were in perfect condition, although unvarnished. In cases of this sort, of course, a good deal must depend upon the character of the collodion, for very many samples of films absolutely would not stand such treatment.

But, as the collodion process gradually popularised photography, and large numbers of prints had to be produced from the same negative, which consequently underwent a good deal of rough usage, more attention had to be given to the varnish, not only in order to prevent direct physical injury, but also to protect the negative film from the action of the more or less damp-silvered paper with which, in printing "long runs," it was constantly in contact, with the result that, under the combined action of spontaneous decomposition and the action of light, the whole of the varnished surface was darkened or blackened until it became practically impervious to light. Under such circumstances it was customary to remove the old varnish by means of spirit, and after-revarnishing, if the operation were performed in good time, it restored the negative to its pristine condition. In milder cases it might suffice to remove the surface stain by rubbing with cotton-wool saturated with weak spirit containing a little cyanide of potassium. It has been placed on record that the negatives comprising the late Mr. William England's admirable series of

stereoscopic views of the International Exhibition of 1862 had to be regularly submitted to his remounting process once a week.

But the chief point in these early experiments was this, that the varnished surface became the surface of the negative, and, though perhaps of little value as a physical protection, it was all-powerful in taking up small stains, abrasions, and scratches, and what not, and more particularly the much-dreaded contact stain from damp albumen paper. It took the stain, and when the stain became too prominent a pledget of cotton and a little ether and alcohol would put matters right in a few seconds.

That contains the whole question of solvents in a nutshell. If you want a strong resisting waterproof varnish, dissolve your celluloid in acetone, or, better still, amyl acetate, and make it thick. If you want a less robust varnish, but still one that can be called impermeable, dilute the above with methylated spirit gradually, or, better, with wood naphtha; but, if you only want a good negative varnish that will thoroughly protect your film from moderate rough usage as well as from stains of all kinds, that is easy of removal, and, more over, that is cheap and can be made at home, take the following: Take old celluloid films, previously thoroughly cleaned and, cut into narrow strips. Place in a bottle with methylated spirit until they become perfectly soft, then add little by little methylated sulphuric ether of specific gravity .720 or .730 until just dissolved. After allowing it to stand for some time, thin it down to proper using strength with a mixture of equal parts of methylated spirits and ether. Ether is recommended in preference to acetone on account of its more rapid drying, and with a varnish of this strength we should use these with not the slightest probability of its showing any structural faults. When complete, the varnish is slightly opalescent, but this disappears when it dries on the glass.

So far as collodion was concerned, this constituted the whole difficulty, but when gelatine plates came into vogue it was soon recognised that the conditions were materially different; but chiefly it became plain that the varnish, instead of soaking into the negative film, and forming, as it were, part of it, remained isolated on the surface, with very little adhesion, and certainly without forming any sort of protection, since the underlying negative film was the stouter and tougher of the two; but, when we add to this that the so-called protective varnish retained its semi-crystalline and porous nature while the negative film remained at least partly soluble in water and amenable to its influences, it needs little reflection to show that the effect of wet or moisture upon varnished gelatine negatives was found to be infinitely more disastrous than if no protection had been attempted.

Numerous were the remedies attempted, but perhaps the most useful, and at the same time the most common-sense, was the plan of coating the negative first with collodion to form a basis for the varnish to hold on to, and afterwards varnishing. In practice, the latter portion of the process soon came to be omitted, and to the present day very many workers follow no other caution than that of coating the negative when dry with good transfer collodion. The immediate effect of the coating of collodion was to render the gelatine film practically independent of most of the damp troubles that hitherto existed, for, even if the protective film were porous enough to allow moisture to pass, it was flexible enough to admit of the gelatine swelling freely, and then resuming its original form, instead of splitting up and disintegrating the varnish, as was formerly the case. This was the first step in the direction of

a celluloid varnish, inasmuch as it was the first attempt to introduce a preparation with a gun-cotton basis.

The next step may also be said to be in the direction of a celluloid varnish, though developed in an entirely different manner. After very many futile efforts to produce a perfectly impervious varnish, it was discovered that the end was partly, though by no means perfectly, obtained by mixing collodion and ordinary negative varnish in such proportions that they did not mutually precipitate or decompose one another—that is to say, no proportions short of those where the pyroxyline would be precipitated by excess of spirit or the gums precipitated or “chilled” by the presence of too large a quantity of ether. Naturally it was a task of some delicacy to arrive at the very best combination possible, but it was very easy to recognise that each successive small addition of varnish to ordinary transfer collodion very materially improved its protective power without in the last interfering with its structural qualities or flowing powers. At any rate, we have seen twenty years or more ago more than one such sample of varnish that was little behind celluloid in quality. We believe that the Autotype Company actually placed varnish for gelatine negatives on the market that was prepared on somewhat this principle.

#### Lubricant for Glass Stoppers and Stopcocks.—

One of the most annoying yet frequent occurrences in dark-room work is to find that some particular stopper has become so fast as to render its loosening a matter of difficulty. To obviate such trouble, an excellent plan is to lubricate all stoppers with vaseline. There are, however, circumstances under which this substance is inefficient, and Mr. Francis C. Phillips, in the *Journal of the American Chemical Society*, has been studying the question, with the result of devising a perfect lubricant. The conditions it should satisfy are: It should adhere to glass, and not be loosened by water; it should be little affected by changes of temperature; it should not be saponified by alkalis, and should be sufficiently translucent, when used with a stopcock, to render visible any clogging of the aperture in the plug, and to show whether air spaces exist between plug and wall of cock. He gives two mixtures: 1. Melt 70 parts of pure caoutchouc, and stir in 25 parts of spermaceti and 5 of vaseline; in winter a little more of the latter should be used. 2. The same proportion of caoutchouc melted, and then stirred with 30 parts of unbleached beeswax.

**Photography at Funerals.**—The ubiquitous photographer seems to be cropping up everywhere and on every occasion, and often not much to the credit of photography. One of the most recent dodges that has come under our notice by report is that of photographers attending at cemeteries to “snap-shot” the mourners at the grave while the funeral service is proceeding, on the speculative chance that copies of the photographs may be purchased by the different mourners. We have just said that the “dodge” came under our notice by report; and so it did in the first instance. But it was our painful duty a week or two ago to attend the funeral of a dear old friend at a suburban cemetery, and we were passed on the road by a local photographer on a bicycle, with a camera case on his back, followed by an assistant on another cycle, with the stand and other paraphernalia, tearing along at a “scorching” speed. After the service was over in the chapel, and on arriving at the grave, we noticed the camera planted so as to command a view of the last sad ceremony—and the photographer at work. We are pleased to say that, on this occasion, the ubiquitous photographer’s work, commercially, was futile, as the proofs were received with disgust, also that the photographer is not likely to have anything more to do for the bereaved family. Would it not be well for District Councils to put a stop to this kind of thing by speculative photographers in the cemeteries under their control unless they attend on a special com-

mission from the owners of the grave, as it is repugnant to the feelings of most of those whose painful duty it is to attend funerals of departed friends, unless, indeed, they have extremely morbid tastes.

**Precipitation of Gold by Charcoal.**—In reference to the description of this process lately noticed in these columns, a suggestion is made in *Nature* by Mr. James C. Richardson to the following effect: “By some process, accelerated, no doubt, by surrounding physical changes, there is formed within the charcoal carbon monoxide (and also carbon dioxide), which is a precipitant for gold. . . . I may mention that I am now using carbon monoxide as an industrial precipitating agent in gold-winning.” The writer of the original note appends a foot-note stating “that the idea of carbon monoxide as the precipitating agent is an old one, and that the main objection to all the theories put forward to account for the charcoal precipitating the gold is that they are not supported by the results of any published experiments.”

**Pyroxyline Mirrors.**—An extremely ingenious method, devised by Mr. A. Mallock, of making perfect plane mirrors of a diameter up to and even exceeding two and a half inches in diameter, was communicated to a recent meeting of the Royal Society by Lord Rayleigh, who thought they would be extremely useful where good definition and extreme lightness were desired. It may be imagined that they would answer admirably for reversing purposes in a camera, a true plane mirror of that size being ordinarily a somewhat costly affair. The mirrors are formed by stretching the thin films left on a surface of water after a few drops of a solution of pyroxyline in amyl acetate has been poured upon it, and allowed to spread there over rings whose edges have been ground to a true plane. The contraction of the film in drying causes it to approach so closely to the plane in which the edge of the ring lies that, when used as a reflector, the definition is equal to that obtained from a worked glass surface of the same area, at any rate until the film is more than two and a half inches in diameter. A two-inch mirror may be made weighing considerably less than ten grains. Mr. Mallock’s chief difficulty lay in silvering the films, and he had not entirely overcome it. Success in this point seemed to depend entirely on securing extreme surface cleanliness, both of the films and the silvering bath, the films being in this respect enormously more sensitive to surface tension influences than glass.

**More Spurious Paintings.**—Some time ago we alluded to the discovery, on the Continent, of a manufactory of spurious pictures of well-known artists, and to the fact, as reported, that many of these fictitious works had found a home in some of the principal private collections of America, they having been purchased at a price that should have ensured their genuineness. Now the *Vienna Neue Freie Presse* warns the public that spurious pictures, bearing the forged signatures of the Viennese painter Leopold Karl Müller, who died some years ago, are being offered for sale as originals alike in England and America. It is a little significant that in all these disclosures of spurious works of art the principal purchasers are American and English. It is a notorious fact that there are in existence more works by the old masters than they ever painted; also, that doubts are thrown on the authenticity of some of them in our national and royal collections. Sometimes photographs of these works are issued, and are therefore accepted as reproductions of the work of the masters whose name they are reputed to bear.

**The Turner Exhibition.**—A few weeks ago we called attention to the fact that a loan exhibition of Turner’s works was to be held at the City Art Gallery, Guildhall. The Exhibition was opened by the Lord Mayor on Monday last week, and will be open to the public free, daily, Sunday afternoons included, for some months. This Exhibition is specially instructive to photographers in more ways than one, and it is the first time that so many works

of this famous artist have been shown side by side in one and the same gallery at the same time, hence the student has the opportunity of seeing and comparing the artist's work at different periods of his life. It is well known that Turner's earlier work was very different from his later productions, and many prefer the former to the latter.

MUCH of Turner's later work was very broadly treated, and in some respects his style has been affected by photographers of the Salonistic type, though Turner, it may be said, did not revel in "dismal swamps," mud flats, and suchlike subjects. He luxuriated in brilliancy and vivid colours, perhaps to a greater extent than many appreciate. There is one point in this show that is especially interesting to photographers, namely, that many of the pictures on view have been engraved by some of our most famous engravers, and the prints are familiar to all. It is therefore instructive to compare the engravings, while the opportunity lasts, with the originals and see how the engraver has translated the brilliant colours of Turner into monochrome, and whether they are in accordance with what has been laid down as the theoretically light values of the various colours. Amongst engravers there has always been a divergence of opinion as to how certain colours and tints should be rendered in monochrome, and not all seem to be in accord with the theory. Photographs of many of the pictures have also been published, and it will be interesting to the photographic student to see how the colours have been translated by photography and compare them with the originals and the engravings from them. Many persons, we know, prefer some of the engravings to the originals. As we have just intimated, this Exhibition is of special interest to photographers, and probably such a complete collection of Turner's works will never be shown again, so that the opportunity of seeing them should not be lost.

#### ON THINGS IN GENERAL.

THE London and Provincial Photographic Association often manages to have papers of practical value on what might yet be termed every-day subjects, the value of the papers being estimated not entirely on their own merits but on that of the discussion that follows. Indeed, they may be often likened to Archbishop Whately's well-known edition of Bacon's *Essays*, in which there is a vast amount of annotation to a small modicum of essay. I was led to this train of thought by a recent paper read at the Association, and the attendant discussion on the different aspects of the question of good *versus* bad lenses. Now, every one knows that one man with artistic feelings could, with a piece of tin with a pinhole for a lens and a cigar-box for camera, produce photographs of a far more interesting and artistic character than another who made use of the very latest things in dear lenses and the highest class of wood-work in cameras. Yet, because the results in the former case were so good, the latter so poor, it would be idle to infer that in a general way the tin pinhole was the lens to be chosen by the comparatively impecunious amateur. So, in regard to Mr. A. T. Harris's arguments against the use of high-class modern lenses in favour of cheap ones of limited capabilities and feeble rapidity, the fact that many "exhibition pictures" have been taken by the latter is no argument in favour of their selection by the amateur. I am happy in remembering many pictures in the older exhibitions that could not possibly have been taken with a "landscape lens," and, when the present craze for very rough surface work has had its day, we may be quite sure that plenty of prints will be shown that are evidently the work of large apertured lenses free from astigmatism. The discussion was pregnant with terse statements—some true and new, some new and not true. I leave it to my readers' unaided perspicuity to say to which category belongs Mr. Everitt's statement that it was "possible to get a picture of a fast-galloping horse in one-five-hundredth of a second in which even the hair of the animal was defined." Many of us will remember Ruskin's saying that in a particular drawing "Turner's pencil did not move over the thousandth of an inch without meaning," and, when accused of extravagant hyperbole, Ruskin made an excellent defence, which is worth any one's while to look up if he can obtain access to

*The Literary Gazette* for November 13, 1858. I should much like to hear Mr. Everitt's defence of the statement that an animal's hair could be defined while the animal moved through a space of about half an inch during the exposure.

Speaking of lenses reminds me of a mild criticism I made in my last letter regarding an extraordinary pronouncement attributed to Mr. Dallmeyer. Now, no one can ever accuse "Free Lance" of writing with a pen tipped with gall. Influenced by a spirit of camaraderie, I took no notice of numerous errors from the same source, which were obvious slips of the pen that had escaped a careless printer's reader; but, when a respected name in optical science was, in effect, held up to ridicule, I felt bound to interpose a word of warning. It would have been far better for the writer to have admitted a pen slip than to have attacked me in the manner he did and landed himself in further error, which he could not put down as clerical. However, notwithstanding all that, I will quote out of the essays aforesaid where Bacon wrote: "It hath been an opinion that the French are wiser than they seem, and the Spaniards seem wiser than they are," and will assure my readers that the writer in question is like Bacon's French, and is wiser than he seems, as shown in his Dallmeyer dicta.

One of the most remarkable discussions that has ever appeared in a photographic journal is that lately appearing on assistants. Heaven forbid that I should speak lightly of the cruel injury and wrong done to assistants by robbing them of their specimens, though, as I have before said, their losses in this way are not infrequently attributable to their own carelessness in regard to distinguishing and marking their work when sent away; but when a man airs his grievance to the effect that he has applied several times for places without success, and sometimes without getting a reply, I am tempted to exclaim, Where has the man been vegetating up to now? In the fierce race for bare existence that characterises the present time, fortunate is the man out of place that has not to wait weary months, if not years, to get in again, unless his capabilities are high, and then, to express the Editor's words by a common apophthegm, "the best is bound to come to the top." Let the complaining assistant interview any large employer of "gentlemanly" labour in the guise of clerkships and ask his experience when he advertises for a clerk at a guinea a week—"1000 applications," he will probably be told. Yet to become an efficient clerk requires years of drudgery before sufficient skill is obtained to be able to get a market for it. How difficult, then, in a time of admitted depression in what may be termed photographic industry, must it be for a really competent man to obtain employment, still more difficult for the man who can do work [such only as could be done by any schoolboy with a few months' practice. It is, unfortunately, too true that the very first principles of business are utterly unknown to unfortunate men of this kind. What is their labour worth? What is any labour worth, efficiency in which can be obtained by a year or two's practice? Not as much as a crossing-sweeper's earnings. If a man is determined to rise in his profession, to become specially skilled in his work (this not to be taken on his own valuation), to study the science and the theory of what he does, he will probably succeed. Every first-class photographer knows that, if he advertises for an assistant, he gets scores of applicants from men of the highest capacity, judged by their own standard, but a few solitary and single applicants of real skill, judged by his own standard. A photographer who can't do anything better than a lad of a couple of years' experience won't get as much as a bricklayer, and, candidly speaking, is not worth it.

I have just spoken of want of knowledge of elementary principles of business matters. Photographers, as a rule, are very deficient in such knowledge. Some of the cleverest photographers I have known have been miserable failures when they have gone into business on their own account simply through lack of business knowledge or training. I believe that, as "poets are born, not made," so it is with business men. Still, training will sufficiently make up for natural inaptitude to enable a good man to run a successful studio. Could there be a better example of this than the wail of the writer under "Business Disputes" in the Correspondents' column for April 7? He buys a business on the strength of the returns for the previous

two years, and, finding his own takings do not amount to half this sum, now wishes to repudiate the last instalments of payment of the purchase money simply on these grounds, although he knows that the seller's old operator has opened an opposition shop close by! Such diminution of returns may afford grounds, of the slightest, for suspicion that the returns shown him may have been falsified. Let him have them examined by an expert if he likes, but before that is done to assume at once that he has been cheated is actually monstrous.

"H. M." last week ends his letter with wise and weighty words. He says, "To an extent unknown in any other science, the knowledge of the many has become the knowledge of the few." Gelatine dry plates owe their existence to a clever amateur. Who will ever forget Bennett's photographic "snap-shot" of the woman emptying a jug of water, which first conclusively proved the possibilities of gelatine emulsion work for rapid exposures? His methods were freely given, but, as "H. M." says, the improvements made by the wholesale producers are now guarded jealously by manufacturers as secrets it would be ruinous to divulge.

When I speak of amateurs I mean amateurs in the true sense of the word, not nondescripts such as the one who recently sued a customer before a County Court Judge for the price of an enlarged photograph he had supplied. Quoth the Judge, "Why do you call yourself an amateur photographer if you are doing that for money?" The nondescript one replies: "I am not in business." "Not if you are making photographs and selling them?" "I mean," says the plaintiff, "that I don't earn my living by it." To which the scathing retort was made by his Honour: "It seems absurd to call yourself an amateur;" and a little later he told the "amateur" that he had been parading as a jay in peacock's feathers. Do these "amateurs" include their amateur earnings in their income-tax returns, I wonder?

## PORTRAITURE.

[A paper read before the Edinburgh Photographic Society.]

THE subject which I deem it my privilege to bring before you to-night is a well-worn one; but, as two people seldom entertain identical ideas on one subject, I may perhaps be able to give some details which my experience in portraiture has enabled me to acquire. Edinburgh has, from the very earliest days of photography, held a prominent position with regard to portraiture, and I need only here mention the well-known name of D. O. Hill, many of whose admirable works can be held up as examples to the present day. In fact, if we come to study the question, I doubt if our up-to-date professional photographer would find that he had made progress adequate in proportion to the facilities which are placed at his disposal. Take, for instance, the infinite variety of textures available in paper, and the wonderful improvement which art and ingenuity have invented in the methods of printing and in the science of optics, and last, but not least, in the marvellously increased speed of the sensitive film. My verdict is, we have not. I can recall some of the meetings of our brethren in the seventies, when all our energies were directed towards the obviating of streaks, oyster-shell markings, and pin-holes resulting from the silver bath; and when we take into consideration that the present photographic generation has been relieved of this, and numerous other difficulties, for the past fifteen or twenty years, it seems that a corresponding amount of study has not been accorded to the art side of photography.

Portraiture, you will grant, is by far the most difficult branch of our art. Take any other object as a subject for the camera, and, with sufficient technical knowledge, the obstacles are by no means insurmountable; but what else in creation can compare with the human countenance for mutability and variety of change? Health, temper, frame of mind, or dress, are but a few of the contending difficulties which meet the professional photographer, for to combine a pleasing portrait with a true likeness must be our end and aim. As our subjects are seldom perfect, it is necessary to keep constantly before our mental vision a distinctly ideal form, so that when deformity presents itself, or even a slight deviation from our idea of perfection in the human form divine, we may be able to discreetly modify the defect by the various means at our disposal, without entirely obliterating any point which may tend to spoil the individuality of our sitter, and so attempt a deceit which is a distinct violation of the rules of true portraiture.

## DIFFERENT POINTS OF THE FACE.

I think that most of us are cognisant how very unmerciful photography at times is apt to be; but, if we can only bring our artistic knowledge to bear upon the difficulty, it is often more easily solved than we should imagine.

Shall we look for a few moments at the different points of the face, remarking, first of all, on the mouth.

This is perhaps the feature, and especially in ladies, which requires the most careful observation, and on no account should the mind of the subject be influenced to a consideration of it, or a total destruction of the natural lines will probably be the result. Much may be learned from a cursory conversation with a sitter, during which an opportunity is gained of observing the delineation of the mouth when in animation or repose. In many instances the youthful female mouth may be treated with the lips apart, but in this case a full illumination of the opening is necessary, as the tendency in photography is to obtain too dense a shadow, thereby destroying the delicate transparency that we admire in nature. Children's mouths are a fascinating study, with their beautiful, soft, mobile lines, full of a sweetness and repose seldom or ever to be found out of childhood. Unfortunately for photographers, however, this ideal expression is not the one most generally appreciated by the loving mother or auntie who may accompany the juvenile sitter, and a grin which distorts the mouth into a grin extending from ear to ear is more likely to meet with their favour. With advancing years the susceptibility of the mouth to change is more apparent than in any other feature. The development of characteristics, the results of certain habits, the circumstances of joy or sorrow, all tend to leave an indelible mark upon this most tell-tale feature, leaving compression of lips, and destroying with lines and twists the delicate mobility of youth. All this calls for our careful consideration in portraiture, and demands our utmost skill in dealing with it. For instance, a twist may often be modified by a judicious pose of the head, and I shall make a reference later on to the treatment of lines.

## THE MOST ATTRACTIVE FEATURE OF THE HUMAN VISAGE.

And now to pass on to the most attractive feature of the human visage, which is indisputably the eye.

Again I must revert to the child. Here we find the eye abnormally large, a fact accounted for by the growth of that organ not being in accordance with other features. Both in children and adults this charming feature cannot receive too much attention, for here you have to deal with the "windows of the soul." All our most interesting subjects have fine eyes. While on this subject, it is useful to remember that a certain latitude is allowed in the higher art of painting with regard to the size of the eye. But this is not a concession that we can apply to the photographic art. There are, however, certain conditions in our practice which tend to an opposite result, unless we are on our guard, among which I may mention the indiscriminate use of light as being the most guilty factor, and it should always be borne in mind that too much light has the effect of dwarfing the eye. Stray lights are also detrimental, and are frequently caused by the mischievous use of white reflectors placed in too close proximity to the sitter. The seat of sweet feminine character is in the outer corner of the eye, and more particularly on the lower lid. Our greatest portrait painters fully recognised the importance of this most telling feature, for, when receiving or parting with their subjects, the eye was always the first and last to attract their attention.

We have now dealt with the two leading points of the face wherein mainly rests the expression, and the treatment of the other features, viz., the nose, chin, and ears, must depend on the judicious point of vantage which can only be selected by the photographer after a study of the contour of his sitter's head. The ugliness of a face may be decidedly modified by choosing either full, three-quarter, or side view, and the calling into requisition of the charm of light and the mystery of shadow, remembering that the naked truth is deceitful.

Comparisons are proverbially odious, and in comparing the works of portrait painters with those of the photographer it has been remarked that the latter only gave "the soot of the flames" (the subject of the criticism was perhaps printed in carbon), the reference being made to the extreme difficulty of securing an intelligent expression by photographic means. We are, however, consoled by the thought that the painter has many advantages which are denied to the photographer; and, if the painter be endowed with mind, he has ample opportunity of calling forth the mind of his model, while a machine cannot evoke a soul. This is supposed by many to be the true relationship of photography to art so far as portraiture is concerned, and so we must be content to

worship afar off, and if we cannot evoke souls it is still permitted to us to exercise the little mind we may have at our disposal towards the consideration of the other portions which go towards making a complete picture, and we will therefore now consider the background.

#### THE BACKGROUND.

With regard to this subject, as showing the importance of the background with relation to the figure, Rubens is reported to have said to the person who recommended to him his son as a pupil sufficiently advanced to be competent to paint his backgrounds, "If he can do that, my friend, he stands in no need of my instruction."

The late Mr. Gleeson White, while editor of the *Studio Magazine*, wrote an article, which appeared some time ago in the *Photogram*, taking as his subject, "The Use of Dark Backgrounds in Photography," and I am proud to say he honoured me by selecting some of my studio work to illustrate his ideas.

But, to return to the practical view taken by the majority of our portrait workers of this all-important subject, it would seem that it is the one point which receives the least attention of any, and I feel sure that, if it were to receive the careful study due to it, portraiture would advance by leaps and bounds, and we should no more have our eyes offended by the incongruous productions which meet our view in the various shop windows.

A young English photographer waited upon me in my studio some time ago, and apologised for troubling me, trusting I should have no objection to him taking a look round. In the course of conversation I asked him if he had any specimens of his work with him, whereupon he produced a packet of cabinet portraits for my inspection. The weak points in them were immediately apparent, all the pictures being taken with a background of an equal grey tint, against which all the ugly lines of the figure were shown up to perfection. I returned his packet of photographs in discreet silence, but, in answer to his earnest solicitation for my opinion on them, I conducted him to my front window, and pointed to a building at the foot of the Mound, where he could spend an hour with great advantage, recommending him at the same time not to trouble as to the light or treatment of the heads, but simply to study the manner in which the figures rested against the backgrounds. I had not the pleasure of another visit from that gentleman, but I heard indirectly of his safe arrival home with his ardour slightly damped. Velasquez, Vandyke, Reynolds, and Raeburn afford the intelligent student ample opportunity for studying what is most desirable to achieve; at the same time I regret to say that we labour at an art which has its limits.

From a photographic point of view, difficulties often present themselves which seem well-nigh insurmountable, for figures often require adjustment to a certain background, which we have neither the power nor time at our disposal to paint according to our idea, and the effect which we have in view must therefore be accomplished in some other way. This may be done by placing our background at different angles to the light, and shading certain portions of the figure. For example, if the outline on the shadow side of the head will not bear emphasis, the tone of the background at that particular part must be equal in depth to the shadow, so that the two blend. This leading principle applies to the whole marginal line of the figure, and it thus follows that we must have a clear conception of which points in a subject to emphasise and which to subdue. This also accounts for the reason why so many eminent portrait painters finish the heads of their models before proceeding with the background, or even deciding on the ultimate arrangement for the pose of the figure, so that in commercial portraiture it is almost impracticable to secure always an absolutely harmonious effect.

#### FASHION AND PHOTOGRAPHY.

The attire of the subject is one of the most important items when considering the background.

If the drapery is graceful and becoming, it will bear greater boldness of treatment, and may with advantage be allowed a place in the picture second to the head.

But one of the photographer's most serious barriers in the way of artistic effect is the constant contending with ugly fashions, the sleeve not infrequently proving a most troublesome point, its shape and size influencing in a large degree the scale of the head. The large full sleeve, which, I regret to say, has just become a thing of the past, was, in my opinion, admirably adapted for the square bust portrait, although it certainly had the disadvantage of emphasising the defects in short stout figures when full-length pictures were required. The present style of sleeve calls for special treatment, and only in exceptional cases is

becoming. The arm usually emerges from a tuft of satin, or other stiff material, about the size of a breakfast roll, and in bust portraits the short piece of arm which appears between the fulness of the sleeve and the lower margin of the picture seldom looks well.

But these and other vagaries of fashion are good tests for the photographer's powers of composition.

#### CHILDREN'S PORTRAITURE.

Children make delightful pictures, their simplicity and serene unconsciousness being qualities which lend themselves readily to the painter's brush or the less pretentious camera; but to do them justice in either painting or photography needs a special study and love of infantine life. Reynolds was a great lover of children, otherwise our eyes could never have feasted on such art-treasures as *Lady Smith and her Children*, and many others.

His child models were, however, invariably well dressed, and here again, as in adults, the photographer is met with a blank wall of opposition. A new stiff or starched dress is a garment usually brought into requisition for the important occasion, when an old, soiled, or flimsy frock would, doubtless, have been the very thing could the unhappy photographer have made his own selection. In the case of very young children, the neck and shoulders should always appear, although there is a danger of making the head abnormally large, unless discrimination is used in allowing the dress to fall below the shoulders, thereby giving the appearance of greater width.

If the usual short frock is used, nothing is prettier for a child than a full-length figure standing alone, especially if taken from a low elevation, which gives the little subject dignity, and shows to advantage the limbs, which are always interesting; but this is, doubtless, the most difficult portrait to secure with any amount of success. The charm of our daily work with children is the constant anticipation of what may next reveal itself.

I will conclude with a few words as to the practice of retouching. As in landscape work, so in portraiture, we get too much detail; but, while not for one moment losing sight of the fact that all the predominant darks in the face are conducive to likeness, yet the excessive details which make their appearance on the intervening spaces can bear modification, as such detail is only troublesome to the eye, and not of service as regards the likeness; but, when the retoucher directs his energies to the wholesale removal of the darks, then the likeness at once begins to suffer. You remember my reference to seat of sweetness in the female eye, and, if the fulness under it is removed, with it goes all the poetry.

WILLIAM CROOKE.

#### OZOTYPE.

SINCE Mr. Manly read his paper on this process before the Royal Photographic Society many experimentalists have given it a trial, with more or less success. Some, however, have found that the image has not been so sharp as the negative, it having a somewhat blurred appearance—much as if the paper had been put upon the wrong side of the negative. Now, it is quite conceivable that, under certain conditions, this may be the case, because the action of the light on the sensitised paper is transmitted to the unsensitised carbon tissue, and this action may extend laterally and thus cause a blurring of the finer details, particularly with a thickly coated paper and a thickly coated pigmented tissue. We have as yet had no time to experiment with the process, so cannot give our personal experience of it. In the results that have come under our notice the ordinary single-transfer paper and carbon tissue have been used, and it is quite possible that the gelatinous coating of one or both papers is too thick for this process, and thus permits of a lateral spreading of the light's action in transmission. If this should be the case, the remedy would seem to be to use a more thinly coated paper for the actual printing, and a tissue containing a large proportion of pigment and a small amount of gelatine, i.e., a highly pigmented tissue. Of course, in every fresh process, difficulties are to be expected at first, and in this instance we do not for a moment imagine that they are insurmountable.

#### WITH QUEEN AND CAMERA AT CIMIEZ.

BEING sent on a journey to "photograph the Queen and her surroundings" is not such an easy matter as may be supposed, especially when she is staying in a foreign land; it is a mission that bristles with many difficulties. The French Government are naturally very anxious for the Queen's safety when she visits the south of France, and the utmost precautions are taken to ensure this. Sentries are duly posted round the

grounds and building of the Hôtel Regina, the patrol makes its rounds, and there are frequent marchings to and fro of the bands with their escorts, which all make extra difficulties and add to the show of military force.

Photographers, however, have not so much to be afraid of the soldiers as of M. Paoli and his large corps of plain-clothes officials, which includes some of the sharpest men from the detective force of Paris. It is their business to be all eyes and ears, and not to be heard, until danger threatens or they think it does. They are in all sorts of disguises, and lounge about as if they didn't care a button what happened next; but just act a little suspiciously, and you will cause these fellows some uneasiness. I am using, amongst other cameras, a  $7\frac{1}{2} \times 5$  (stereoscopic) hand camera, which, with its six double backs and leather case, makes it weigh rather heavy. Where I cannot use a stand camera I use the hand. To set up a stand camera in front of the Queen's private entrance would be madness; so, when I thought no one was looking, I hid my case and slides in the grounds of the Grand Hôtel (next to the Regina), but at a place where I could keep an eye on them and watch if any one touched them. I then walked past the Queen's private entrance and "snapped" it, then went back to put my camera in its case, but it was gone! One of M. Paoli's eagle-eyed friends had—I don't know how—obtained possession of it; but, on proving that I was a harmless Englishman, I got it back.

Before the following incident, I should have mentioned that I had orders to stay one week and get what was possible. First of all I went to the English Consul—one of the politest consuls I have yet met—who told me that he could do nothing for me, but that I was to write to the Queen's Courier—Mr. Dossé—who had in hand all Royal matters. I wrote, and in reply obtained a nicely worded letter, saying that photographing was strictly forbidden in the Royal apartments and in the grounds. The first two days I spent getting what pictures I could, and during that time I noticed many people who were visitors to the hotel (the Queen has the west wing) walking in the garden, and so I thought it possible that I, too, could do the same, even if I went to the extra cost of staying for a day or so at the hotel (I was staying at Nice, about two miles away). A letter, however, to the manager brought a favourable reply, which told me that I might enter the garden any time when the Queen was not therein. This was fortunate, as I was able to add considerably to my stock of pictures, and, moreover, could get an excellent "pitch" when the Queen left the hotel for her afternoon drives.

On the third day I was about the hotel as usual with my camera, when a French detective came up to me and said that I had been about there for three days, and it was time I departed for good. On this occasion I did not understand French, and accordingly shook my head. This rather annoyed him, I think, for he looked round to see if there was any one who could speak English, and, finding none, he took hold of my camera and gave me a sharp push. I still clung to my camera, and by degrees got out of his grasp. I then walked away—straight into the gardens, and up to the Royal balcony. Oh, that man's look, and the noise he made! Within less than a minute there were half-a-dozen detectives and two soldiers running, as for their lives, to the garden entrance. They were coming for me, I knew that, so I sat calmly down and got out my permit from the manager. They arrived, and seized hold of me, and just at that moment an English-speaking detective arrived. I said nothing at the time, but held up my permit. I shall never forget the look on their faces—I felt sorry for them, for they were only doing their duty, but with monkey madness, and not in a quiet, gentle sort of way. Every day after that, I entered the garden and photographed without any objection whatever.

The number of hand cameras about here is enormous. One day I counted thirty when the Queen drove out, but I have only seen two tripods in use—my own and that of a well-known member of the London and Provincial. Photographers here all grumble because Her Majesty wears such deep black veils; it is almost impossible to see her features, let alone to photograph them. Authorities say it is because of the sun and dust, but may it not be as a foil to photographers? The photographs on sale here are as a rule faked. The Queen's face is white compared with the others in the carriage—generally Princess Henry of Battenberg and Princess Victoria—who do not very often wear veils. At the Diamond Jubilee all photographers blessed that sunshade; here is also a sunshade and in addition a thick black veil. Stereoscopic cameras are well in evidence, for this is in France, be it remembered, where stereoscopic work is popular. Stereoscopic views are for sale in nearly all the windows, as also are stereoscopic post cards.

RICHARD PENLAKE.

#### THE PACKING OF P.O.P.

At the London and Provincial Photographic Association, on April 6, Mr. A. Haddon referred to a question discussed three weeks ago touching the packing of some gelatino-chloride paper. Briefly, the facts are these: Some P.O.P. was sealed up in zinc cases, which were soldered with an acid flux, but, on reaching its destination in East Africa, it was found to have gone to different depths of a mahogany colour, which action the makers ascribed to the fumes driven off in soldering with an acid flux. Mr. Haddon did not think that the fault lay with the zinc. He was

reading an article by Professor Burton, writing from Formosa, in which it was stated that English plates as a rule did not reach him in the best of conditions, while plates of German manufacture did. The explanation advanced for this was that each dozen was packed in an hermetically sealed zinc box. According to what was said at the time this matter was being discussed, every one, he thought, came to the conclusion that plates were far more susceptible to alteration from emanation from the zinc than was paper. He did not know for certain what fluid the German maker used for soldering, but imagined that it was hydrochloric acid or zinc chloride, in which case exactly similar fumes would be given off when sealing up either plates or paper. We have a definite statement that no deterioration in the plates followed this course; and, further, that the only plates which reached Mr. Burton in good condition were those which travelled in zinc boxes. To return to the matter of the paper which was returned from Mombasa, and of which he showed two sheets, one much darker in colour than the other, he thought some few experiments which he had conducted might be either of present or future interest. The condition of the paper suggested to him that it would be a useful direction in which to experiment if he took up the task of restoring the paper to its original state, or, at least, making it once more serviceable. He therefore submitted the paper to the action of certain reagents, which would restore the paper to as nearly as possible its original colour. Chloride of copper or acidified potassium bichromate were used, and a piece of the darker of the two papers so treated was now shown in comparison with an unchanged portion. The colour was largely discharged, but paper was left in only a feebly sensitive state. To remedy this and restore sensitiveness, some absorbent of chlorine was required to be added. It would be found that a brushing over of the paper, after bleaching as described, with either acid citrate of silver or nitrite of potash, effected this object. A print on a piece of the least-stained paper showed, notably in the sky, how much the paper was improved by bleaching in the manner described. Mr. Haddon then exposed a piece of paper to daylight until it was as dark as it could go, and bleached it in chloride of copper, followed by bichromic acid, but, strange to relate, this treatment did not restore to the paper its original whiteness. One end he then brushed over with nitrate of potash, and the other end with acid citrate of silver, leaving the central portion untouched. The influence of the chlorine absorbents was plainly visible in the prints, but by daylight the paper, in this case, showed a peculiar violet colour. Mr. Haddon's experiments were of an interesting character, and may prove useful in saving paper which has lost its whiteness in one way or another.

#### [INSECT PHOTOGRAPHY BY ARTIFICIAL LIGHT.

At the London and Provincial Photographic Association, on April 6, Mr. T. E. Freshwater gave a few short notes on a simple method of photographing insects by artificial light, and showed a large number of examples from specimens in his own collection. He used an ordinary camera and tripod stand, with this modification, that a tilting board was introduced between the two, the object being to enable the lens to be pointed downwards at right angles to the usual position for that instrument. The only other apparatus called for was a small glass-topped table, about fifteen inches high, a convenient substitute for which would be found in an inverted stool with a slab of stout glass (preferably plate) laid over the feet. The tripod is placed so that the lens and camera overhang the centre of the glass table. The object to be photographed—butterfly, beetle, moth, &c.—is placed on the glass table, and, if it be of a dark colour, a piece of light-coloured paper is put on the ground below the table, so as to form a contrast and throw the object into relief. The same effect is obtained with a light-coloured object by using a dark background. The image can then be focussed on the ground glass to an approved scale, after which steps may be taken to expose; magnesium ribbon, giving actinic rays approximating to daylight more than anything else applicable, is preferable. It is burned near the lens, away from its field of view, in such a manner that any shadow of the object may be cast to one side, such a shadow in the picture generally being very unsightly. By having the glass table, the shadow would, in most cases, be lost on the background. In lighting the object, care should be taken that one side is not more brightly illuminated than the other, and this may be done by burning the ribbon as high up as possible and as nearly as may be above the object. In photographing a series of insects, where it is important that relative size should be true, they should be all taken with the same extension of camera. The exposure constitutes the crux of the question. Unless properly lit and properly exposed, the negatives will be worthless. If one had time, daylight would be preferable; but many had little daylight to spare for these experiments. About seven inches of ribbon, with a rapid, thickly coated plate, is usually enough to give a good representation for detail, gradation of light and shade, &c., and for the developer pyro soda was commendable. Chloride of paper was perhaps the best for the print, giving as it did a bright image. His own work was done with a Dallmeyer stigmatic lens. Little stopping down was recommended,  $f/11$  serving well as a rule. As regards the use of orthochromatic plates, he was not sure that they were needed, some photographs of butterflies like the Red Admiral and the Painted Lady being rendered well enough with

an ordinary plate. None of the specimens need be taken off their pins. Any reflection may be prevented by blackening the heads, and they may be stuck into a piece of cork on the glass table during operations. Books, manuscripts, &c., are equally well negotiated in the above manner.

### SOME NEW POINTS IN PLATINOTYPE PRINTING.

On Friday, April 7th, the members of the Leeds Photographic Society foregathered at the rooms in the Philosophical Hall, Park-row, Leeds, to hear the Rev. J. Beanland, M.A., lecture on the above interesting subject.

The President (Mr. Godfrey Bingley) having introduced the lecturer, the latter remarked that he might commence his lecture first of all by saying it was not so much new points he specially desired to draw the attention to as to correct wrong impressions in connexion with the working of the paper. At the outset he wished to correct the idea that the process was a difficult one to work. When he commenced the study of photography, on the advice of a professional friend, he started to print with platinotype, and he had stuck to it ever since.

The whole secret of the successful working of the paper was careful attention to details. His advice to them was not to avoid a single detail in connexion with the printing of platinotype paper. Personally, he usually bought a three-sheet tin containing seventy-eight  $5 \times 4$  pieces. Before printing, he took the back of the frames out, and put them inside the fender with the cloth part towards the fire. He used a piece of maintosh at the back and dried it before the fire, and the secret of any little success he had had was by paying strict attention to the details, which were not irksome when they had got into the habit of doing them. If they had a negative that would give a good silver print, they might rely on it as giving a perfect platinotype print. It was probably the easiest of any paper to work. They could do as they liked with it; print from a harsh negative and get a soft result. This could be done in half a dozen ways—one way by shading the picture and reducing harshness; another way by developing with a brush, and the oxalate developer mixed with glycerine on the parts we should call the whitewashed parts, and the solution very much let down to the sooty part. A further way was to turn your print where the extra detail was not of much consequence, using a strong solution at the back of the print, force up every particle of the image, and then turn it round to the front. He had been asked by many platinotype-workers how he accounted for the black salt following the brush when using it, or leaving the paper when put into the developer to develop. His answer was that he had never had that fault with platinotype printed in the shade. It had nothing to do with the water; but, if the paper was printed in bright sunshine, it got hot, and caused the sensitiveness to leave it.

There was another erroneous impression he would like to correct. It was said the paper was more expensive than P.O.P. He had gone into the matter carefully, and found that the cost of printing, toning, and fixing four dozen half-plate P.O.P. prints cost about five shillings, and, after making allowances for failures, they might reckon on getting thirty successful prints; with platinotype, the same number, half-plate size, with chemicals, cost 7s. 6d., and the average number of successful prints might be put at forty-five.

Workers were now using sodium phosphate instead of potassium phosphate, and with the cheaper chemical they got identically the same result. Developing the D salts with potassium or sodium phosphate, you get those lovely cold tones that nothing can touch. If they had any doubt as to the paper being damp before printing, it could be dried before the fire; and put into the developer a little potassium bromide, and the result would be that the moisture would be considerably lessened and the damage minimised to a considerable extent.

The prints could be toned when finished, and there were half a dozen toning baths which could be used—uranium, or any of the ordinary developers; but he recommended Thomas's formula to give a good tone to a platinotype print. One that he specially desired to draw their attention to was platonic chloride—a fifteen-grain tube in fifteen drachms of water; tone and acidify it with any of the chemicals they liked.

In conclusion, he thought he had said sufficient to show them how this paper might be successfully worked.

A formal vote of thanks to the lecturer brought a most interesting meeting to a close.

### THE BUILDING OF A PICTURE.

At a meeting of the Leeds Camera Club, on Wednesday, April 5, Mr. W. E. Tindall, R.B.A., gave a lecture on "The Building of a Picture," illustrated by lantern slides shown upon the screen. The lecturer dealt with the definition of the word "picture," showing that a picture should be something to convey to the mind the impressions of others received from the beauties of Nature. The architecture of early times left large spaces on the walls, and the frescoes that were then painted upon them were to fill up these spaces, and the only difference of to-day is that we now fill our spaces with movable or detachable pictures, whilst theirs were not portable or detachable. The object, then, of a picture should be to show a remembrance of some subject, and pleasing to the eye. For purely artistic purposes, painters undoubtedly drew largely on their

imagination, but there was no greater delusion than that they could sit down and dash off a sketch which might be enlarged and elaborated without trouble. Art is governed by certain rules, and no artist who respects himself can afford to neglect them. It is independent of the subject, as the most ordinary thing, when touched by a genius, is infused with the highest charm, and the artist must be in perfect sympathy with his subject. The lecturer dealt very fully with the importance of unity in composition, harmonious in idea, and dominated by a motive, and said that in their photographic work they should endeavour to get one leading idea to show the keynote of their picture when finished, so that it might not be just so many trees, rocks, or bracken stalks. In the relation of light and shade, it might be taken generally that two-thirds of the picture should be in light, the other third dark; in a varying degree, their highest light in the lightest part, the deepest shadow in the darkest part. It was a mistaken idea to force the highest lights by contrast with the darkest shadow; it destroyed unity, and made the picture spotty. Many other points were dealt with, and a series of slides to illustrate the studies in the building of the picture *Peter the Great*, by Mr. Seymour Lucas, were exhibited, after which he showed slides from the works of the great masters, and pointed out the lessons to be derived from their study.

### KODAK FILM IN SPECTROSCOPIC PHOTOGRAPHY.

SIR NORMAN LOCKYER has lately been experimenting, and very successfully, with flexible film, with the idea of adapting it to spectroscopic photography. The large concave Rowland grating which Sir Norman Lockyer is now using for his solar spectroscopic photographs has 2000 lines to the inch ruled on its surface and is of  $2\frac{1}{2}$  feet radius, giving a spectrum of 30 inches long. The focal plane of this grating is of necessity considerably curved, in fact the plane of accurate definition at the edges of the field is about 0.5 inches in front of the similar plane at the centre. It is therefore impossible to get a sharp photograph of the whole spectrum on a glass plate, in fact not more than 18 to 20 inches of the spectrum can be brought into focus on the same plane. This difficulty is, of course, got over by the use of a flexible film, which can be bent to the curvature of the field.

The Kodak Company have sent us a print of one of Sir Norman's photographs taken with this Rowland concave grating. It is thirty inches long, and shows the arc spectrum of iron with a comparison spectrum of the sun from wave-length 3600 to 5200. Sir Norman Lockyer also hopes that, by using films instead of glass plates at the next solar eclipse, he will be able to obtain a greatly increased number of photographs, owing to the rapidity with which the film can be shifted in the short space of time available for photographic operations. At the last eclipse the photographic work was concentrated on obtaining a series of photographs of the chromosphere both about the time of beginning and end of totality. By careful drill Mr. Fowler and Dr. W. J. S. Lockyer were both able to secure ten photographs at each of these important periods, the time occupied in making each series of ten exposures being twelve seconds. An apparatus for carrying films is also being designed which can be adapted to the spectroscopic cameras at present in use in the laboratory and observatory.

### AT THE CAMERA CLUB.

With Chief Justice Rayner, of Lagos, in the chair, and Mr. Alfred Lloyd on the platform to give an illustrated account of his experiences in Africa, and more especially his dealings with the inhabitants of the Pigmy Forest, the Camera Club was assured of a very crowded room. Mr. Lloyd's adventures were the topic of many newspaper articles a few months ago, and many will remember that, as an *attaché* to the Church Missionary Society, he spent some years in the very heart of Africa, mixing with the tribes and learning their language. But it is another thing to see the explorer in the flesh, and hear him tell of his wonderful adventures, and more interesting still to see projected on the screen the various snap-shots which he had taken with his camera. It cannot be pretended that these were fine examples of photographic art, but they were taken under all kinds of difficulties; the boxes which contained the undeveloped plates were occasionally dropped in rivers, or trodden on by stampeding elephants or buffaloes, and the merest tyro knows that such treatment is not good for embryo negatives. Had it not been that we were made aware of these accidents by flood and field, we should have put Mr. Lloyd among that numerous class of explorers who take with them photographic apparatus with very little knowledge of what to do with it. We are bound to say, too, that Mr. Lloyd makes a mistake in having his slides coloured. A good picture, well coloured or rather tinted, is admissible, but when the slide is a poor one, and the colourist has taken upon himself to paint in details which are wanting—a pair of eyes here and a mouth there—he is apt to produce a rather ludicrous result. This was the case with some of Mr. Lloyd's pictures.

The traveller started on his long journey at Zanzibar, and traversed the great African continent from east to west. He came upon the camps occupied by Mr. Stanley in his famous journey, but generally took new routes, and found himself in districts never before visited by white

men. Stanley had an army of followers, but Mr. Lloyd had with him, during the greater part of his travels, only two dusky companions. It is true that he started from Zanzibar with 500 men, but several deserted and several died from fever, so that, when he arrived at the Victoria Nyanza Lake, twenty-five only remained to him. After this he was able to borrow small escorts from the various villages through which he passed; but, as we have already stated, he eventually found himself with a bodyguard of two.

For two years Mr. Lloyd found his home in one village, where he learned the language and made friends of the natives. Here he had some singular experiences, two of which we may recount. He showed a photograph of some two hundred natives, black as ebony and shining as if they had been French-polished, squatted on the ground, and waiting to see him in the early morning. This was a common experience, for the natives have a firm belief in the efficiency of European medicines, and most of these poor creatures were afflicted with some disease or other. At this rate the stock of medicaments was soon exhausted, and the traveller found himself in a difficulty. The idea occurred to him that very little would satisfy these children of nature, so he hit upon the device of tearing up bits of old newspapers and gumming them on to the sore places. As a result the crowd gradually dispersed, each man having stuck upon his body a bit of *Times* newspaper.

The other experience was of a more delicate nature. A young woman made a daily practice of visiting him, each time bringing with her an offering of fruit. This was most acceptable, but, at the same time, the recipient wondered what it all meant. By questioning some of his "boys," he discovered that the young woman's aim was matrimony, this being the peculiar way in which a bachelor was approached in that part of the world. He got out of the difficulty by quietly hinting to the young lady that whites did not enter into marriage contracts with coloured people, and the matter dropped.

It was after this two years' sojourn that Mr. Lloyd commenced his memorable journey towards the Mountains of the Moon and the Pigmy Forest. During most of the time he had to depend upon his gun for food, waterfowl and monkeys forming the chief part of his diet. Coming to the territory of Uganda, he made the acquaintance of Mwengi, the king of that country, of whom he showed a photograph. This picture was noteworthy because it included, besides the king, a man crouching behind his chair. It seems that this monarch had a suspicion that the camera would bring him some harm, and he therefore caused another man to share the risk, so as to diminish that which threatened his imperial self.

The chief interest of the narrative was centered in that portion which dealt with the Forest of Pigmies, and it was disappointing that no photographs of the interesting little people were forthcoming. This was readily accounted for by the fact that the forest is so thickly planted that the sun's rays never penetrate the foliage, and nothing would induce the pigmies to step out into any open country that was adjacent to it, nor would they keep still for a single moment in order to allow of a time exposure.

Mr. Lloyd evidently did much valuable work on behalf of future explorers, for he gained the confidence of the natives with whom he came in contact, and showed them that white men travelled for other purposes than those of mere conquest and spoliation. It must be regretted that his photographic efforts were not more fortunate, for a series of negatives representing peoples and countries hitherto unknown to civilised humanity would have been invaluable. At the same time, it must be remembered that this intrepid explorer carried his life in his hands, and it is a matter of congratulation that he has returned to his friends unscathed, for he has spent many months in a country inhabited by cannibals and lawless savages, and has encountered besides lions, leopards, crocodiles, and other wild fowl which certainly do not add to the security of existence.

#### YORKSHIRE PHOTOGRAPHIC UNION.

A MEETING of the Committee of Delegates in connexion with the above Union was held at the Grammar School, Bradford, on Thursday evening, April 13, when the voting papers, which had been circulated by Mr. Ezra Clough, the Secretary *pro tem.*, were handed in, and, on a scrutiny of the same, the following gentlemen were elected officers of the Union:—President: Mr. Percy Lund. Vice-Presidents: Mr. Godfrey Bingley (Leeds Photographic Society), Dr. Hollingworth (Hull Photographic Society), and Mr. Rowntree (Scarborough). Business and Recording Secretary: Mr. Ezra Clough. Assistant Secretary: Mr. J. C. Coultas (Leeds). Treasurer: Mr. Jackson (Keighley).

The proceedings throughout were of a most enthusiastic and harmonious character, and in the hands of such a well-known body of officers the success of the Union seems assured.

A sub-Committee, consisting of Messrs. Briggs, Coupland, Clough, and Coultas, were appointed to arrange a date for the annual excursion, which will be held at an early date, probably June 14 next, at Selby. It was also decided that the Secretary print and circulate a list of the available lecturers to the secretaries of the various societies, members of the Union, as soon as possible.

In regard to the criticisms which have been from time to time made as to where the two free lectures, to which all societies who join the Union are entitled, were to come from, it transpired that the Committee have sufficient lectures now at their disposal to successfully carry out this desirable object.

#### NOTES FROM THE WEST OF SCOTLAND.

THE question of the permanency of photographic prints has been somewhat prominently brought forward in Glasgow recently, and several of our leading photographers have been giving the matter their closest attention. In one instance, where the experience of a leading portraitist is concerned, the matter has gone so far as to lead to the exclusion of all printing papers having a gelatine base, permanency being deemed of the first importance in connexion with all the photographs turned out from this studio.

An important prosecution came under the Petroleum Acts recently in one of the Glasgow Police Courts, when the manager of a large engineering company was fined in the modified penalty of 10*l.* for permitting six cylinders of calcium carbide being stored in the company's yard. There would appear to be considerable difficulties in connexion with the introduction of acetylene gas in studios as well as for other commercial purposes, and no doubt, were it not for the stringent rules imposed by local authorities, this beautiful light would be in more general use than it is, especially for photographic purposes. Still, however, it steadily progresses in favour both for the lighting of studios and other commercial purposes, a striking instance of the latter being its adoption by one of the local railway companies for the lighting of their fleet of coast steamers, upon which it has given entire satisfaction.

Long-distance excursions are becoming popular with our local amateur workers. Doubtless, these are prompted by the very moderate week-end railway fares that are now established all over Scotland. A large contingent, taking advantage of such facilities, quite recently made an excursion into Northumberland, making Alnwick their chief centre. The trip is very highly spoken of.

Lantern operators, especially those who understand the benefits derivable from a good pressure of gas being brought to play upon a heavily packed mixing jet, will be glad to learn that an improved form of fine-adjustment valve will soon be placed upon the market. Several of the best operators in cinematographic projection have entirely discarded the use of regulators and taken to fine-adjustment valves, the reason being, no doubt, the unlimited amount of pressure they can command with the latter when used as cylinders.

The decision given by Sheriff Spens in the recent action against the Shettleston Camera Club has given much satisfaction to photographers all around the West of Scotland. Had Sheriff Spens not ruled the action incompetent, the case would most likely have gone before a jury, incurring considerable expense; as it is, even much sympathy is expressed for the Shettleston Camera Club having to pay extra judicial expenses under such uncalled-for circumstances.

#### A FRAUDULENT PHOTOGRAPHER.

At the Rutland Quarter Sessions recently, John Lee Dadford (54), photographer, was indicted for unlawfully and knowingly, by certain false pretences, obtaining the sum of 2*s.* 6*d.* in money from Tom Peckett, at Oakham, on December 9. He was further charged with similarly obtaining the sum of 2*s.* 6*d.* from John McIlvride; and also a like amount from Annie Davis.

Mr. A. W. Tuck prosecuted.

Tom Peckett, butler in the employ of the Right Hon. G. J. Noel, Catmos, said accused came to the house on December 9 last, and asked for permission to photograph the place, which was allowed. He then offered to take witness and his fellow-servants, and they were grouped at the back of the house, where prisoner went through the usual process of photography. He took them twice, but he did not change the slides in the camera at all, but after the second time he looked into the camera, and said it would make a very good picture. He and the others paid prisoner half-a-crown each for a copy of the photograph, but he never received one. He should not have paid the half-crown if he had thought the prisoner had not actually photographed them.

Inspector Wilson said he apprehended the accused at Wood Green Police-station, and, when charged with the offence, he said he had been very ill, and he had lost his wife, which had nearly driven him mad. He added that, if the people proceeded against him, he hoped something would happen to make them wear a band on their arm, the same as him. He said the negatives were at Enfield.

Prisoner went into witness box, and said he took negatives as stated with a proper camera, and plates, and he had them with him, but they were undeveloped. He had been locked up since his arrest, and had therefore not had the opportunity of getting the negatives prepared, or he should have shown that there was no swindle about it. He had sent for them, and had only received them the previous day, but until they were de-

veloped they could not be produced. A statement to the same effect, written by the prisoner, was read.

Mr. Tuck called the attention of the jury to the fact that prisoner, from December 10 to February 17, when he was arrested, had the opportunity of developing these negatives, but he did not choose to do so.

The jury found prisoner guilty, and he also admitted a conviction for misdemeanour at Bristol Assizes, in February 1896.

Mr. Tuck said he had been instructed to call the attention of the Bench to the fact that the police had received a tremendous number of complaints from all over the country against the prisoner about this sort of thing, and the conviction recorded against him was for offences of an exactly similar character.

The Chairman said they had only gone into one of the cases against him, and no doubt the jury had done perfectly right in finding him guilty, and if he persisted in this sort of thing he would probably be sent to penal servitude. He had been in prison six weeks awaiting his trial, and he would now have to go back again for nine calendar months, with hard labour.

## Our Editorial Table.

### THE THORNTON-PICKARD SHUTTER WITH TIME-EXPOSURE VALVE.

Manufactured by the Thornton-Pickard Manufacturing Company, Altrincham.

WE have had placed before us a specimen of the latest make of the famous Thornton-Pickard time and instantaneous shutter. This is in mahogany, and a careful inspection of it shows it to be a beautifully finished piece of photographic cabinet ware which works like a charm. The shutter is fitted with a speed-indicator, showing it to have an exposure range of from one-fifteenth to a ninetieth of a second, and it also allows

of time exposures being given by the adjustment of the lever at the side.

The novel feature of the shutter that is deserving of especial mention is the time-exposure valve, fitted to the pneumatic tube, which permits the photographer to give short-time exposures of  $\frac{1}{15}$ ,  $\frac{1}{20}$ ,  $\frac{1}{30}$ , 1, 2, and 3 seconds. This facility is obtained in the following manner:—

A pneumatic ball screws into an air-escape valve, to which, at the other end, is attached, by a screw connexion, a rubber tube.

A small hole is pierced in the air valve to allow of the air escaping,

and upon the face of the valve a circular revolving disc is screwed to regulate the air escapement. An arrow mark or pointer is engraved on the centre of the valve face, and, to obtain any of the various exposures marked upon the revolving disc, it is only necessary to turn the disc until the number indicating the required speed is opposite the fixed pointer, set the shutter for "time" in the ordinary manner by placing the shutter lever opposite the word "time," then, holding the ball in the palm of the hand, give the ball a decided squeeze, and maintain the pressure until the exposure is completed in precisely the same manner as at present.

Thus, with the practical certainty of obtaining with the new time-exposure valve accurately measured exposures from one-eighth of a second to three seconds, a valuable power is placed in the hands of the photographer, who has hitherto had to give such exposures by pure guess-work. The Thornton-Pickard shutter, thus improved up to date, is the perfection of what such an instrument should be.

### THE GAMBIER-BOLTON CAMERA.

Manufactured by W. Watson & Sons, 313, High Holborn, W.C.

If any one's experience in photographic work should be worth embodiment in the production of a hand-and-stand camera, we need not trouble to look beyond Mr. Gambier Bolton to supply it. He has for years been photographing animals at home and abroad, in circumstances and amid surroundings of peculiar difficulty, and so he may be quite safely depended upon for advice in the choice of a hand camera, which shall be a reliable tool for enabling one to turn out good work, and not the mere toy of the occasional dabbler.

Mr. Bolton puts his advice into the concrete form of a hand-and-stand camera, now being introduced by Messrs. Watson, the points of which may be gathered from the following description:—It consists of a mahogany box, covered with black leather, to be used with one lens. It has rack-and-pinion focussing for lenses of six-and-a-half inches focal length and upwards; a square Thornton-Pickard focal-plane shutter built into the back of the camera, rising motion to the front, and a reversing frame at the back, for either vertically or horizontally shaped negatives; doors divided in half, to open on hinges (to the sides of the camera) by

pressure on a small "push knob" on the front (of the top) of the camera; a loose focussing frame for use when the camera is fixed to a stand. Immediately in front of the shutter, and inside the camera, is a large but light mirror, which reflects the whole of the image thrown on to it by the lens (the right way up) on to a full-sized, square, ground-glass finder on the top of the camera. On this ground glass the object to be taken can be focussed with the greatest accuracy, as round the ground glass is a four-sided dark chamber, which cuts off every ray of light not necessary for focussing purposes. The exposure is made by pressure on a round "push knob" near the back (left side) of the camera, the focussing screw being on the right side and near the front of the camera. This pressure on the "push knob" releases the mirror, which flies up swiftly, and directly it has cleared the top of the plate it discharges the shutter automatically, and the exposure is made. The mirror is then turned down again by the brass handle on the top (right side) of the camera, and "snaps" audibly when it is in its proper position. A dark slide can always be carried in its proper position in the camera, ready for immediate use, and the shutter of the dark slide can be kept drawn out—when the camera is in use—the whole of the back of the camera being encased in a leather cover, which, being hinged at the bottom, falls down when unfastened at the top, and when a plate is being changed. A small square door at the back of this leather cover is used for focussing purposes when the camera is fixed to a stand for "time" exposures, thus doing away with the inconvenient focussing cloth altogether.

An inspection of the camera and a study of the manner in which it is worked persuades us that it is just the thing for the hand-camera worker bent on serious photography. You carry your camera with a plate always ready for exposure, and the full-sized finder image perpetually in view. One simple movement dislodges the reflector from the axis of the lens and releases the shutter, and your exposure is made.

The practical details and minutiae have been well thought out. We can cordially recommend the Gambier-Bolton camera to those requiring a simple, efficient, and workmanlike instrument.

### CATALOGUES RECEIVED.

FROM Mr. Henry F. Purser, of 33, Hatton-garden, E.C., wholesale agent for the lenses of the Rathenower Optische Industrie-Anstalt (late Emil Busch), we have received a supplementary list of new lenses which his Company are introducing to the English market. These include the

following series: A wide-angle aplanat, working at  $f/15$ ; the periplanat,  $f/9$ , giving an angle of  $80^\circ$ , suitable for portraiture and landscapes; cinematograph lenses, working at  $f/4$ ; projection lenses and Universal sets on the casket system. The Buech lenses are both cheap and good, and we have seen many most excellent photographs produced with them.

Taylor, Boxall, & Co., 86, Lewin-road, Streatham, S.W.

MESSRS. TAYLOR, BOXALL, & Co.'s list gives prices of the various kinds of work they undertake, viz., bromide enlargements on paper and opal, carbon enlargements, finishing and painting enlargements, mounting, ivory miniatures, pastels, &c.

MESSRS. TAYLOR, TAYLOR, & HOBSON, of Leicester, send us a copy of their new catalogue of lenses. The volume includes an excellent paper on "The Principles of a Lens Action," and a new form of tables of conjugate foci. In addition to the Cooke portrait lenses, Messrs. Taylor, Taylor, & Hobson now include the smaller Cooke lenses, Series V., which have the same aperture as lenses of the rapid rectilinear type. Reference is also made to a new focussing mount and the Cooke extension lenses.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
24.....	Bradford Photo. Society .....	<i>The Joys and Sorrows of Photography.</i> P. E. Newstead.

29.....	Hackney .....	Excursion: Bostal Heath. Leader, H. W. Dunkley.

### ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 18.—Photo-mechanical Meeting.—The Right Hon. the Earl of Crawford, K.T. (President), in the chair.

#### A "BRACKET" CAMERA STAND.

Mr. E. M. SMITH exhibited a bracket camera stand, intended to replace the tripod when photographing in awkward situations. It could be attached to a window-sill, balustrade, ladder, fence, &c., the camera being affixed to a platform capable of an extension of about four feet by telescopic movement and permitting the direction of the camera upward or downward or at any desired angle.

#### APPARATUS FOR HALF-TONE WORK.

Mr. W. GAMBLE exhibited some of Messrs. Penrose's latest apparatus for use in the photo-mechanical processes. The first was a screen and plate-holder, intended for attachment as a dark slide to any existing camera, for small workers who do not care to go to the expense of a large camera especially for half-tone work. The shutter being of the draw-out type, and a ground-glass screen being provided, the focus could be adjusted with the screen in position; and there was an ingenious rack-work motion for setting the screen distance. Another exhibit was a new prism box possessing great accuracy. The manufacture of prism boxes from thin sheet metal, making the back and sides of one piece and then fixing on the ends, and also by using several separate pieces, had not been found satisfactory, and the present exhibit had therefore been made by making a solid brass casting of the  $90^\circ$  angle of the box, and planing it with great accuracy, so that it was practically as true as a set-square; it was then

a simple matter to slip in the prism and cap the back of the box. It was arranged to screw on the front of the lens, the hood and cap being placed on the front of the box, the result being a very neat, compact, and accurate arrangement. Mr. Gamble said he had recently been able to get prisms which would read on the spectrometer to absolutely  $90^\circ$ , and he could read to half a second.

A new form of arc lamp was also shown, adapted for use on a stand, or by hanging in any desired position or at any angle.

Mr. A. HADDON asked the diameter of the graduated scale by means of which Mr. Gamble could read up to half a second of arc, and how he tested the absolute planeness of the surface of a right-angle prism?

Mr. GAMBLE said his spectrometer had a seven-inch diameter of scale, and he took the reading first by rotating the table, and then by rotating the telescope and taking the mean of the two readings. For testing the flatness of prisms, he had a plane parallel plate of quartz, which, when pressed into contact with the surface of the prism, showed Newton's rings very plainly; if the rings were irregular, and not concentric the prism was not flat, but the evenness of the rings was a fairly good indication of the flatness of the prisms. The quartz plate was five millimetres thick, and it was, of course, necessary that it should be parallel and plane.

The conversation next turned on the subject of the preservation of mirrors, Mr. IGNATZ HERBST saying that he found it necessary to resilver once a fortnight or oftener in London, and once a month in the country.

Mr. W. E. DEBENHAM suggested the practicability of enclosing the mirror in a box, one side of the box being screwed as nearly as possible airtight to the lens, and the other side having a glass flap fitting against a rubber flange, a small tray of chloride of calcium being enclosed. The flap need only be opened during exposure, and the mirror would thus be kept in a dry box.

Mr. GAMBLE thought this a good idea, but the difficulty would be to get the operators to close the flap after use. He thought they would generally leave it open.

#### ELECTRIC TRANSMISSION OF PHOTOGRAPHS.

Mr. AMSTUTZ showed some examples of work done on his electro-artograph engraving machine. He said that some twelve years ago he commenced original research upon the subject of the electric transmission of pictures, and was able at that time to take a relief photograph and transmit it electrically to considerable distances, reproducing it at the receiving station in the shape of an engraving ready for printing purposes. So far as he knew, the first work in this direction was done in 1850 by an Englishman, Mr. Bakewell, who was followed by Casella, whose apparatus was brought into actual use in France and Russia. Casella prepared sketches in outline, by means of an ink consisting of shellac and alcohol, on very thin sheets of tin, so as to make an insulating surface; a small stylus was made to travel over the plate, and when it touched one of the insulating lines the circuit was broken, and when it dropped upon the conducting surface the circuit was complete. This system, however, needed an expert artist of both ends, and the result when received had to be engraved by hand before it was ready for printing. Mr. Amstutz made a carbon print upon celluloid, and fastened it to a drum at the transmitting station, a similar drum being placed at the receiving station; a delicate stylus was arranged to travel over the print, the relief of which caused the stylus to be raised or lowered in varying degrees, and it was connected with a multiplying lever which actuated other mechanism, so that, when the stylus was at the lowest point, the current on the line leading to the receiving machine was strongest, gradually reducing as the needle rose on the higher parts of the picture. At the receiving point the varying strength of the current pulled a V-shaped graver into a coating of wax, celluloid, or gelatine, on the drum, and the picture was thus interpreted in parallel line upon the receiving machine, the engraving so made being ready for immediate mounting and printing, or a stereotype could be made from it. The electrical parts of the system, as it at present stood, were simply those used for ordinary Morse transmission, the length of the dots and dashes being controlled by the lights and shades of the picture. The carbon reliefs shown by Mr. Amstutz, as used for transmission, were inspected with much interest and admiration, but he had no transmitted prints for exhibition, as he did not wish to enter into details as to some features of the receiving apparatus.

#### COMING EVENTS.

April 25, Technical Meeting. A demonstration of the making of glass diaphragms, from "thin" to Newton's "very black" stage, by Mr. T. Bolas, F.I.C., F.C.S. May 9, Ordinary Meeting. "On the Photography of Colours," by Mr. Sawyer Shepherd.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 13.—Mr. R. P. Drage in the chair.

Mr. EDWIN BANKS referred to a formula recently published by Professor W. K. Burton for a combined toning and fixing bath. Coming from such an authority, it would naturally carry considerable weight amongst photographers, for which the speaker was particularly sorry, seeing that any combined bath was necessarily sulphur toning and nothing else, and, if so, why should not sulphur toning be done properly? Mr. Burton's theory, on the face of it, looked plausible enough. His aim was to maintain the neutrality or slight alkalinity of the toning bath, and to this end he added powdered chalk, which remained inert unless the bath showed a tendency to become acid. Mr. Banks thought it was a question whether such a bath would give any deposition of gold at all—if any, it would be very slight, and further stated that one could get all the colours the bath would give by the use of a hypo bath in which there was no gold at all. In the early days, when the sel-d'or bath of hypo and gold was much in use, it was known that pure sel-d'or would not tone; it required something to upset its equilibrium before toning action could follow. In the same way Mr. Banks said he had been curious to ascertain if Mr. Burton's neutralised toning bath gave any action. He took a print and washed it so that all acidity was removed, and found that no action took place when the paper was treated with the neutral.

toning bath; but, where not previously washed, the action was instantaneous, an apparent toning taking place. He asserted that there was no deposit of gold in a combined toning and fixing bath unless there were some free acid present. Sulphur toning, pure and simple, took place, and the addition of gold to such a bath was an utter waste. He had failed to detect any gold in the print passed round. There were many things which, added to hypo baths, produced actions resembling gold toning, but it need hardly be said that it was not necessarily a gold tone because it looked like one. His last advice was that, if people would use combined baths, they should not continue to throw gold down the sink—hypo was cheaper.

Mr. J. E. Hodd brought up a large collection of the newer hand cameras in illustration of the subject before the meeting.

#### MODERN HAND CAMERAS.

No examples of the twin-lens pattern were included, the speaker withholding his patronage therefrom, but the ordinary one-lens camera was represented by a veritable host of English and American workmanship; McKellen's Cathedral camera, changing plates by a peculiar concertina motion; the Adams's Yale, the Monroe, Premo, and Eastman Kodak and Bullet were passed round, and examined with expert attention. Mr. Hodd ventured to assert that never before had the amateur been so well catered for as at this season.

Mr. Freshwater showed Dallmeyer's new hand camera with a very long extension reaching from two to nineteen inches.

Mr. P. Everitt showed a small hybrid hand camera for lantern-slide work. It was composed of parts of well-known instruments, worked at a fixed focal length, a Steinheil orthostigmat being used. There were no finders, the user relying upon the latitude allowed by the quarter-plate in getting his lantern picture, and the proportion of failures in consequence was not more than one or two in the dozen. It was fitted with magazine changing bag, Thornton-Pickard shutter with self-capping blind, and the negatives shown as examples of its work were very creditable indeed.

#### PHOTOGRAPHIC CLUB.

APRIL 12.—Mr. H. Vivian Hyde in the chair.

Mr. Gask, representing Messrs. Beck, Limited, showed his firm's No. 22 Frena camera, quarter-plate size, fitted with single lens. View-finders of the brilliant pattern are provided, but these are such as to give a stationary image, that is to say, an image of one composition, whether looked at from immediately above or to either side. The makers of this camera have introduced a device for making time exposures other than by the button on the camera. It takes the form of an attachment over the lens aperture, with a flap shutter actuated pneumatically. Some difficulty is felt when exposing in the ordinary way in avoiding a jar to the camera, especially when time exposures are concerned; hence this attachment, with which exposures of any duration, down to one-fifth of a second, can be given. Carrying this principle still further, Messrs. Beck also supply a pneumatic attachment, by which the exposing button itself is pressed and the shutter released, for the same purpose of overcoming the jar likely to follow pressure with the finger. It was explained that, with the interleaving cards supplied by the makers, no action is produced upon the film or emulsion, the whole question depending upon the purity of the cardboard employed.

The Chairman showed a few carbon prints produced by Manly's ozotype process. They were his first results, which, doubtless, accounted for the fact that they were not flattering examples of the capabilities of the process, but at the same time they in no way condemned the new method. The pictures chiefly suffered from want of definition, although the original negatives were particularly sharp. One thing noticed, and confirmed by another speaker, was that the support of the carbon tissue was only with difficulty stripped from the transfer paper in the development, unless it were left for very much longer than was required in the original carbon process.

Mr. Philip Everitt showed one of Thorpe's direct-vision spectroscopes, which, instead of being made of three or five prisms, was constructed with a single prism only. It gives a large amount of dispersion in conjunction with a collodion copy of one of Rowland's gratings, the latter being transferred to the surface of the prism itself. The little instrument was sold by Caplatzi for 15s., and was a serviceable and compact piece of apparatus.

**Croydon Camera Club.**—Sir George Newnes, photographer-in-chief—i.e., Mr. Francis T. Beeson—was the attraction provided on Wednesday, 12th inst. His subject,

#### EXPOSURE AND LIGHTING,

was, as may be imagined, when we remember Mr. Beeson is a lecturer on photography at the London Polytechnic, handled with conspicuous ability. Perhaps the most notable point about the lecturer's remarks was made by the exhibition of lantern slides in which photographic prevarication was strikingly illustrated. Thus the first slide showed an ordinary print of a black hat and a white roll of paper; by merely increasing the exposure and altering the lighting, Mr. Beeson rendered the black hat white and the roll of white paper as a black object. So much for truth of tonality. Mr. Beeson's remarks upon lighting in portraiture were specially useful to amateurs, as much of his work is necessarily done under circumstances which most amateurs are accustomed to; that is to say, his portraiture is seldom undertaken in an ordinary photographic studio, but anywhere, and almost everywhere, in the open or in a room. As regards indoor portraiture, Mr. Beeson showed an admirable likeness taken in an office in London, full of both strength and gradation, and not retouched. He then proceeded to explain how the lighting had been arranged in order to get this result. Thus the lower parts of the windows were darkened, a reflector placed to throw light at about right angle to the main source of illumination, and a light screen (butter muslin stretched on a hoop) was interposed between the sitter

and the windows to soften the lighting. Many examples of bad or improper lighting were shown on the screen, the lantern being in charge of Mr. A. E. Isaacs. As regards exposure, a series of results of successively doubling an exposure were shown, and the relative uses and values of various exposure cards and actinometers dwelt upon. The President, in his comments, referred to the unreliable and un-uniform method of speed-marking dry plates in vogue, which rendered an ideally correct exposure most difficult. He asked the lecturer whether, excluding personal impression, any scientific method was known whereby a photographer can, after development, assure himself that an absolutely perfect time of exposure has been given? Mr. Maclean also referred to the still unsatisfactory stop-marking met with in practice. A book just published dealing with modern lenses gives no less than six different systems of diaphragm numbers. Mr. S. H. Wratten fully agreed with the President and the lecturer as regards the unsatisfactory condition of speed-marking. The H. & D. method is probably at present the best, provided that the conditions of development are constant. At the same time it was well to remember that apart from speed variations, due to using different reducers, the above speed-testing apparatus is at times liable to an error of not less than thirty per cent. Mr. Irving read an extract from a book, which asserted that under or over-exposure is indicated by the absence or presence of positive images on front and back of plate. This, however, only refers to pyro developer and to considerable under or over-exposure. In acknowledging the vote of thanks, which was most heartily given, Mr. Beeson said that the unreliability of speed-marking reached its height when a box of plates marked speed 500 was found on exposure to be slow plates, used for photo-mechanical work, with a speed of only ten!

**Hackney Photographic Society.**—April 11, the President (Mr. W. Fenton-Jones) in the chair.—Members were reminded of the Society's excursion to Buckhurst Hill on the 15th, and to Hadley Wood on Thursday, the 20th inst. The last-mentioned was to be the commencement of a series of Thursday afternoon outings which have been arranged for the coming season. Members' work was shown by Messrs. Roope, Hillam, Westcott, and Ellington. Much interest was aroused in the prints Mr. Roope showed, because they were the successful results of some experiments in Mr. Manly's new ozotype process. In the absence of the author, Mr. Rawlings read a paper by Mr. J. Carpenter on

#### STILL-LIFE PHOTOGRAPHY.

In dealing with flower studies, the author said that simplicity of arrangement should be aimed at. Cut flowers should be arranged in a plane and not in a rounded form, because the latter would require the use of a small stop in order to get sharpness all over, and this would prolong exposure too much. Cut flowers drooped rapidly, and it was therefore necessary to shorten exposure as much as possible or signs of movement would be shown on the finished negative. As to choice of material, the commoner flowers were often more satisfactory from a pictorial point of view than the less-known kinds. It would be found that white, cream, pink, and blue-coloured flowers were the best to photograph, reds seldom being rendered well. The author did most of his own work in a lean-to greenhouse with a westerly aspect, the top light being somewhat subdued. The choice of a background was very important; if the pictures were to be in the form of prints, a dark grey background would be suitable; but, if lantern slides were to be made, then a dead black background would be best. For flower and fruit studies isochromatic plates were indispensable. Exposure should be full and development kept well under control, the object being to get thin negatives full of detail. The paper was followed by about sixty lantern slides of Mr. Carpenter's well-known fine flower studies.

**Richmond Camera Club.**—At the meeting on the 10th inst. a competition in lantern-slide making was decided. Two sets of slides had to be made by each competitor, first, a set of three landscape slides from the members' own negatives; and, second, three slides, two from test negatives, and one a copy of the front cover page of *Pearson's Magazine* for February 1899. The President (Mr. Cembrano) was the Judge of the first set, and the members present at the meeting decided the winner of the second set by vote. Nine competitors sent in slides, and the result of the voting on the second set (which was taken first) placed Mr. Gibson as first in the copy of *Pearson's Magazine* cover, Mr. Huddy first in the slide from the thin test negative, *Strand on the Green*, and Mr. Richardson first in the slide from the dense test negative, *Falls of the Lledr*. Mr. Cembrano then proceeded to decide upon the merits of the sets of three slides from members' own negatives, and after they had been passed through the lantern he awarded the first place to Mr. Gibson, who, having also obtained one of the first places in the set of slides from the test negatives, proved to be the best slide-maker and was awarded the bronze medal offered as the prize. The announcement of the result by Mr. Cembrano was received with applause, and the meeting terminated with the exhibition of some interesting slides by Mr. Gibson of natives of India, Ceylon, and the South Sea Islands.

**South London Photographic Society.**—At the Annual Meeting, held at the Club-room, Hanover Hall, April 5, Mr. Charles Oakden, F.R.P.S., presiding, the HON. SECRETARY read his report, showing the Society in a satisfactory position. The PRESIDENT addressed the meeting, and urged the members to exercise originality in their work, deprecating copying, which, he said, could only be justified in beginners, and then to a very small extent. The officers for 1899 were elected as follows:—President: Mr. Charles H. Oakden, F.R.P.S.—Vice-Presidents: Messrs. A. E. Allen, H. Farmer, J. T. French, S. W. Gardner, M. Howell, and W. F. Slater, F.R.P.S.—Committee: Messrs. E. R. Bull, G. Brown, G. F. Dickinson, A. Fellows, W. Howell, W. R. Jarvis, B. Lyon, E. G. Ruckes, and G. J. T. Walford.—Librarian and Curator: Mr. W. C. Boyce.—Lanternist: Mr. A. T. Harris.—Cycling Section: Messrs. H. Esler (Captain) and C. G. Payne (Vice-Captain).—Delegates to R. P. S.: Messrs. Chas. H. Oakden, F.R.P.S., and Frank Goddard.—Hon. Treasurer: Mr. E. A. Whitby.—Hon. Secretary: Mr. F. Goddard, Woodlands, Vanbrugh-hill, Blackheath, S.E.—Hon. Assistant and Excursion Secretary: Mr. S. W. Whiteman.

**Newcastle-on-Tyne and Northern Counties Photographic Association.**—Any illustrated lecture by Mr. J. P. Gibson, of Hexham, is an event of interest to archaeologists, photographers, and to all the artistically inclined. When, however, he leaves Northumberland, the river Tyne, the Roman Wall, and the castles of the Border country to treat of Rome, the occasion appeals to a wide public indeed. Mr. Gibson, about a year ago, visited Rome, and at the last meeting of the Newcastle and Northern Counties Photographic Society, gave what was but a rough rehearsal of a lecture, entitled

#### IN ROME WITH A CAMERA.

Though his stay abroad was a short one, Mr. Gibson contrived to make a very large number of negatives, and in producing lantern slides from these he has been busily engaged for a considerable time. As yet the lecture and the set of slides are in an incomplete state, but Mr. Gibson was able to show about 160 views of the most interesting archaeological and ecclesiastical features of Rome. In describing these the lecturer imparted in his usual homely but none the less erudite fashion an immense amount of information, some of which may have had the effect of disabusing the minds of some of those present of many cherished misconceptions as to Roman history and customs. In concluding, Mr. Gibson urged photographers to travel to Rome, and made it known that it is no longer the malodorous city which it long had the reputation of being. It is, in fact, the second most sanitary capital of Europe, having a lower death-rate than any European capital, with the exception of London. The lecture was given at the Art Gallery, Newcastle, and, though of a semi-private nature, the room was inconveniently crowded by a representative audience, the local art circle being well in evidence.

#### FORTHCOMING EXHIBITION.

1899.  
April 21-May 13 ..... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

### News and Notes.

**PHOTOGRAPHIC CLUB.**—April 26. "Defects and Remedies." By Mr. E. Dockree.

Mr. L. UPCOTT GILL, 170 Strand, W.C., will shortly publish a book on *Home Portraiture*, by Mr. P. R. Salmon.

Mr. F. V. A. LLOYD of 5, South John-street, Liverpool, asks us to note that, on and after April 24, his business as photographic dealer and optician will be carried on at 15, Lord-street, Liverpool.

**THE AUSTIN-EDWARDS MONTHLY FILM NEGATIVE COMPETITION.**—The prize camera for the current month has been awarded to Mr. H. S. Sharp, Heathfield, Bingley, Yorkshire, for his negative, *Interior of Room*.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Technical Meeting, Tuesday, April 25, at 12, Hanover-square, at eight p.m. A Demonstration of the Making of Glass Diaphragms, Thin to Newton's "Very Black" Stage. By Thomas Bolas, F.I.C., F.C.S.

THE names of the prize-winners in the Warwick Monthly Competition for April are:—1st prize, 10*l.*, Mr. C. Speight, 10, The Broadway, Kettering, *The Carpenter's Shop*; 2nd prize, 5*l.*, Mr. W. McLean, 20, Ponsonby-avenue, Belfast, *Embroidering Sheets*; twenty prizes, 1*l.* each, Messrs. A. H. Robinson, H. Wanless, W. G. Wright, H. E. Watkin, J. W. Oddie, J. W. Reoch, J. T. Rutherford, R. S. Park, W. H. Oakley, W. Baldwin, A. Morrison, E. Coath, J. Brookfield, J. Terras, Nichol Elliot, J. Coath, Ralph Robinson, Dr. J. W. Ellis, Miss Constance Bean, and Mrs. Dumas.

**MISPLACED KINDNESS.**—At the West London Police Court on the 13th inst., Francis Herbert Barnes, thirty-four, a photographer's assistant, was charged before Mr. Rose with stealing a camera and other photographic appliances belonging to Frederick Sargeant, a photographer, of 372, Uxbridge-road, Shepherd's Bush. The prosecutor, out of compassion, employed the prisoner, hoping by this means to enable him to regain his lost character, he having forfeited it through dishonesty. No sooner was he so employed than he began robbing the man who had befriended him. He stole the articles and pledged them. Detective-sergeant Brown gave an account of the prisoner's antecedents, and the magistrate sentenced him to six months' hard labour.

### Patent News.

THE following applications for Patents were made between April 4 and April 8, 1899:—

**CAMERAS.**—No. 7101. "Improvements in or relating to Photographic Cameras." G. W. BASK.

**CINEMATOGRAPHY.**—No. 7278. "Improvements in or connected with Instruments for Taking and Displaying Rapidly Changing Pictures." H. HOWSE.

**BOXES, &c.**—No. 7360. "Improvements in Metallic Boxes or Cases, Cameras, Shutters, or other Articles." J. E. THORNTON.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE SANDELL PLATES.

To the Editors.

GENTLEMEN,—The author of the paragraph in your issue of April 14, on "Photography and Eclipses," seems to be ignorant of working with the Multiple Film Plate. Seeing this, I am surprised he should be so dogmatic. Thus: "Now, it is perfectly evident to any practical photographer that no amount of the 'skilful development' referred to will enable the astronomer on one and the same plate to obtain really useful negatives of the whole area of an illuminated object, the intensity of light radiated from which varies at different positions from 1 to 8000."

Now, Sirs, I know that all practical photographers are not familiar with the possibilities of the Multiple plate, but I know also that many are, and a large percentage of these would not support the above dogmatism, seeing work that has already been accomplished by means of the plates. I can point to work of my own specially, negatives of a brilliant sun, with details in the landscape and dark foreground, the disc of the sun being absolutely sharp and free from halation; and again to a negative of a magnesium flash of five seconds' duration, where full details are shown of the flash, the well-defined Argand spirit flame at the base, and details in the deepest shadow, of black draperies of a figure adjacent, although the only reflectors were dead black walls and ceiling. I do not pretend to measure the differences in intensities of the various portions of the objects photographed, but should imagine they would be not much less, and probably more, than the suggested 8000 of the corona and streamers.

I believe it has been admitted that Mrs. Maunder's negative on the Multiple Triple Plate is the best photographic result yet obtained of a solar eclipse; therefore I fail to see the drift or bearing of your contributor's criticism. It seems to me calculated to harm the progress of, at least, solar photography. Although, Sirs, it may seem that I am an interested party, I feel there is a justification for my troubling you to find space for these lines.

Thanking you in anticipation,—I am, yours, &c.,  
Norwood Junction, London, S.E., April 15, 1899.

J. T. SANDELL.

#### THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

To the Editors.

GENTLEMEN,—Mr. Seamell, in reply to my article upon "Vanishing England" in your last issue, calls attention, as its Hon. Secretary, to the existence of the National Photographic Record Association and its objects. Every one must wish it the highest success; but would not the Association find a heartier, fuller life if, in addition to placing records in the British Museum, it would distribute copies at as low a price as possible to its members? "The trail of the serpent is over us all," and we like to have as much as possible for our money. "Pleasant it is to die for one's country," pleasanter still to live for it, but pleasanterest of all to live for oneself as well as one's country. I have, I trust, the orthodox respect for the British Museum; but, frankly, it is the last place that in an infrequent visit to town as a provincial I would care to visit. The life of the street and the sparkle of the theatre and music-hall are so much more attractive. Still, with the leisure of home and the comfort of my own fireside, I could take a high interest in the prints the Record Association handles. As there must be very many more like myself, would there not be an immense widening of interest were it possible to make this diffusion of result practicable?—I am, yours, &c.,

J. REES.

#### THE TANQUERAY FREE PORTRAITS.

To the Editors.

GENTLEMEN,—You have from time to time kept your readers informed of the "carryings on" of Messrs. Tanqueray of free portrait celebrity. From what a friend of mine who has lately been victimised tells me, it appears the free gift business is still carried on from London, but Paris is where the wires are moved from. My friend was not to be had with the frame dodge; then the picture was offered to him for 8*s.* to cover cost of packing and carriage. This he did not rise to; but, when this 8*s.* was reduced to 4*s.*, he foolishly took the bait. The picture came by rail last week, the railway demanding 6*s.* 6*d.*, charges paid in at London, G.N.R., though the parcel was of no weight, and marked (carriage 4*d.*). My friend has now got, at a cost of 10*s.* 6*d.*, a thing not worth 3*s.* 6*d.*. It seems that any one can take a parcel, say of stones or brickbats, to a

railway company and ask for any amount they like to be paid them, which sum the railway company collect at the other end. By this means Messrs. Tanqueray flourish. If my friend had refused to pay the 6s. 6d., the railway company would have lost that sum, less 4d.—I am, yours, &c.,  
Whitby, Yorks, April 17, 1899. F. M. SUTCLIFFE.

### A SOCIETY FOR PHOTOGRAPHIC PRINTERS.

To the EDITORS.

GENTLEMEN,—There are lessons to be learned in all branches of industry, and some of those branches are terribly slow in learning. I don't think there is a slower-moving industrial branch than photographers. Now, I do not mean to infer that photography does not make rapid strides; perhaps, by comparison with other trades, it is in front, but I mean with reference to self-government. I think, however, I ought to write this under apologies after what has been said, but the idea I wish to ventilate is really of such importance to masters and assistants that one may be forgiven for such a breach.

Comparisons, they say, are odious, but this one savours of success. The building trade is somewhat complicated by its many component parts. We have the carpenter, bricklayer, slater, plumber, &c.; and in photography we have the plate-maker, the operator, retoucher, printer, &c.; but in the building trade we get societies of carpenters, plumbers, bricklayers, &c.; and in photography we get—nothing! I ask, with hundreds of others, Why? Well, Sirs, I don't think the reason is far to seek. Photographers are, no doubt, a jealous lot! This is only natural though, because a printer can be a retoucher, a retoucher can be an operator, an operator can be an enlarger, an enlarger can be an artist—no doubt, many are without knowing it—and an artist can be—"Heaven knows what!" Well, Sirs, how many bricklayers are carpenters, or how many plumbers are bricklayers?

Who is to blame for a non-competent assistant? If I were engaging an operator, I should prefer one who gave all his time and study to posing and lighting, and should not expect him to be competent at half-a-dozen different things and to take entire charge during my absence! No wonder we get faulty men; why, it requires a life of study to be a photographic assistant in our days. Take a materials manufactory, where printing, enlarging, developing, mounting, &c., is included (and there are many). Very often a man is "sacked" if he fails to show himself competent when suddenly moved out of one department to another; and it needs no telling how a man would have to stand out if he could not turn his hand to *variety* in many cases. Now, every assistant stands by and says I must look after myself, I can't afford to join societies, and can't afford to have any restrictions placed on me; I must be free to take what wage I please, and go where and when I please; and as to helping others—pooh! I have enough to do to look after myself.

Having somewhat cleared the ground, I would suggest a society, not for photographers' assistants, but for photographic printers, for instance. We don't want a charitable institute, but a means of centering and ventilating grievances of printers, open to those in situations as printers. Let's have a centre where we can forward letters and book particulars, and where a so-called printer can test his own work against his fellow-printer's, where the trade could make inquiries as to the sort of printer they require, where any correspondence from printers respecting their grievances could be inquired into, and then there will be some hopes of a printer remaining a printer, and being an efficient printer; and then, if operators like to follow suit, so much the better.

Again apologising for this trespass,—I am, yours, &c.,

101A, Fulham Palace-road, Hammersmith, W.

F. G. WILLATT.

### A UNION FORMED.

To the EDITORS.

GENTLEMEN,—The occasional outbreaks of dissatisfaction among assistants which find expressions in your columns would be laughable if they were not annoying. What outsider would dream that these malcontents had an opportunity of joining a Trade Protective Association eight years ago, and simply did it to death by their apathy and cowardice? Who would think that the idea was revived three years ago in another shape; that to-day there is a Union of 3500 members anxious to include the unorganized photographic employees of both sexes and of all ages up to fifty years?

It is, as I have said, both ludicrous and irritating to read one man's promise to "help to form a Union," when he could easily find, on reference to an article in your annual for the current year that such a Union is already in existence.

If any of your correspondents or readers want to save themselves the trouble of ten minutes' search, they can get the details by sending a penny stamp to "Arthur Field, National Amalgamated Union, Maidstone." I think I ought to add another word of dissatisfaction here: Not one in ten of the assistants who favour me with a request for information think it necessary to enclose a stamp for reply. As a rule, those who do so are those who finally join. Nine of every ten neither join nor pay for

information. This is characteristic of the vast majority of the "moaners." They raise themselves to the sacrifice of sending a penny screw to the columns of your long-suffering JOURNAL, complaining of their lot and urging that "something should be done." They mean, something done for them by some one else. As to contributing 6d. to 9d. a week regularly to build up provision against sickness, loss of employment, unjust dismissal, &c., it "isn't in them."

I rejoice to say that an increasing number of far-sighted men and women in the photographic trades are becoming members, but they are still a minority. Nevertheless, the cream of our workers is being gradually organized, and we look forward to the day when competent labour exclusively shall enter into relation with fair employers exclusively.

Age on Entry.	Contribution Payable every Four Weeks.	BENEFIT WHEN OUT OF EMPLOYMENT OR DURING SICKNESS.				PAYMENT AT DEATH TO MEMBERS OF		
		First 4 weeks, per week.	Following 4 weeks, per week.	Next 4 weeks, per week.	Following 12 weeks (per week), in sickness only.	2 years and less than 5 years.	5 years and less than 10 years.	10 years and upwards.
MEN.								
18								
and under 30	2 0 0	15 0	0 10 0	0 7 6	0 5 0	4 0 0	6 0 0	10 0 0
30	3 0 0	1 2 6	0 15 0	0 12 6	0 7 6			
and under 40	2 3 0	0 15 0	0 10 0	0 7 6	0 5 0			
40	3 6 1	2 6	0 15 0	0 12 6	0 7 6			
and under 50	2 8 0	0 15 0	0 10 0	0 7 6	0 5 0			
50	4 0 0	1 2 6	0 15 0	0 12 6	0 7 6			
WOMEN.								
18	1 2 0	0 10 0	0 7 6	0 5 0	0 3 0	3 0 0	4 10 0	6 10 0
and under 50	2 0 0	0 15 0	0 12 6	0 8 0	0 4 6			

Half-benefit only will be allowed to members of six months' standing, and full benefit to members of twelve months' standing and upwards. The period of membership shall date from the first day of the month in which the first monthly contribution has been paid.

Maidstone.

I am, yours, &c.,

ARTHUR FIELD.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2A, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 2A, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

F. T. Blackburn, 2 Station-road, Budleigh Salterton, Devon.—Photograph of the Budleigh Salterton town band.

B. Bethel, Shire-road, Douglas, Isle of Man.—Photograph of Central and Queen's Promenades, Douglas, Isle of Man.

O. Burton & J. W. Burton, Haymarket, Leicester.—Six photographs of Tom Firr, late huntsman of the Quorn Hunt.

A. T. Osbourne, 100, Hessel-road, Hull.—Photograph of group of the crew of the steam trawler "Richard Simpson," of Hull.

IN OUR NEXT.—Copyright; Black and White; Portrait Lens; and others.

BROMIDE.—The formulae at pp. 1049-51 of our ALMANAC for 1899 will answer the purpose.

G. M. LILFF.—You have quoted the formula correctly. We have had no experience of it.

A. W. ANDRÉE (Colombo).—We are very much obliged to you for your letter, which we will keep by us in case we have an opportunity of utilising the information it contains.

C. B. (Melton, Woodbridge).—From the appearance of the print, we should say you were over-exposing; but give us some details of your method of working, the paper you use, &c., and we may be able to help you.

INTENSIFYING VARNISHED NEGATIVE.—J. CONWAY writes: "I have a negative which I much prize, but it is too thin to print well. Can it be intensified, as it is varnished with a very hard spirit varnish?"—Yes, if the varnish be removed. Soak the negative in strong methylated spirit for a few hours, and then gently rub it with a tuft of cotton-wool. Then rinse with some more spirit, and, if necessary, soak again. In this way the varnish may be got off. Then the negative may be intensified in the usual way; but that must not be attempted until the whole of the varnish is cleaned off, or staining will result.

**RESTORING DAGUERRETYPES.**—C. B. asks us to give him address of a reliable firm who will restore a Daguerreotype for him; he also wants an idea of the cost; size, 5x4.—In reply: We know of nobody who makes a speciality of restoring Daguerreotypes. Will some reader assist C. B. with the information he seeks?

**A. R. RILEY.**—1, 2, and 3. It is against our rules to pass opinions such as you ask for, but you could get what you require for 1*l.* or 1*l.* 10*s.* We should, however, advise you to purchase an instrument by a recognised maker. You will be the more pleased in the long run. 4. F-8, bright light, very rapid plate,  $\frac{1}{15}$  second, should give you a good result.

**COLESWEGEN.**—The uranium process will yield you full density, and negatives so intensified may be regarded as permanent; but the latter condition will not be brought about unless the negative to be intensified has been perfectly fixed and all traces of hypo washed out of the film. The fading of your mercury-intensified negative is caused by the presence of hypo in the films.

**RESIDUES.**—BEGINNER says: "I have carefully saved the fixing solution of eight dozen quarter-plates, and the washings and fixings of about twelve dozen prints. There are nearly two Winchester quarts altogether. What ought I to get for the silver in them from the refiners?"—Probably there is not sufficient silver in the solutions to pay for the carriage to the refiner, to say nothing of the cost of reducing.

**SUBDUING LIGHT IN STUDIOS.**—S. & Co. As the sun is only troublesome in the studio during three or four months in the summer, we should recommend you to stipple over the glass upon which it shines with starch paste, to which a little whiting has been added. That will subdue the sunlight, and it is easily washed off when no longer required. Another plan is to have thin tracing linen or paper stretched on light wooden frames, which can easily be fixed and removed when so desired.

**MARKINGS ON PRINTS.**—E. B. says: "I would be extremely obliged to you if you would explain the cause of the markings on enclosed photographs. I may say that they are only visible after mounting when dry."—The markings are apparently due to the mounts, as the brown colouring matter easily comes off when moistened with water. Probably the mountant on the prints softened it, and thus it stains the pictures. If you moisten the mounts with saliva, and in a few seconds touch with a white handkerchief, you will see the effect.

**GLASS TO STUDIO.**—GLASS says: "I enclose a sample of glass with which I intend glazing roof of studio which I am about to build. The reason I am having it so thick is that I can have it in much longer pieces than ordinary sheet glass, the joints of which so soon look objectionable when they get dirty between the parts that overlap. Do you think the sample sent suitable, and will it stop more light than ordinary sheet glass?"—The glass, will by reason of its thickness, certainly stop out more light than thinner glass of a similar kind; but, as it is very free from colour, there will not be much difference. It will, however, require very substantial sash bars to carry it on account of its weight.

**PRINTING QUERIES.**—R. A. BREMAN says: "Are prints toned by platinum more permanent than those toned by gold? 2. Is there a better or more up-to-date book on platinum toning than that by Lyonel Clark, published in 1897? 3. Can you tell me of any commercial printing-out paper with the surface of the enclosed print? This is Gravura. 4. Can you tell me of any paper, chemically pure, to be suitable for home salting, with this surface? I believe Rives put one on the market some time ago."—1. We have no reason to think so if the prints are toned with gold. 2. No. 3. Most of the commercial printing-out matt papers have a very similar surface. 4. The Rives photographic paper is supplied by Marion & Co. and other large photographic houses.

**MARKINGS ON PRINTS.**—A. T. HONEY says: "I have been troubled lately with a peculiar marking or stain on prints, similar to the print enclosed. My printer assures me he has tried every means to prevent it, but every few days there are more or less pictures spoiled from the same cause. It is not confined to the dark mounts, as similar marks appear on pictures mounted on plate-sunk mounts. The starch used is Glenfield's special photographic starch. Solio and Ilford paper are affected equally. Can you help me! I am perfectly satisfied it is caused by bad manipulation, but cannot find out where. It has not occurred in the few I have toned from time to time as a test lot."—If our correspondent had not said that the markings occurred on prints on other mounts, and that they did not arrive when he himself tones the prints, we should have said they were due to the mounts, as the colouring matter upon them easily comes off when moistened. If our correspondent, who is on the spot, cannot detect where his printer goes wrong, we certainly cannot by merely looking at a couple of stained prints. We can only suggest closer supervision.

**COPYRIGHT.**—COPYRIGHT says: "Might I be allowed to ask your advice on the following matter: About Christmas time I photographed some hounds at a meet on my own responsibility with spectators looking on. A week or so after, a party in the group, a well-known local man, committed suicide, consequently I disposed of about forty copies since, not giving it a thought about making the picture copyright, which I think I was justified in doing. Now, do you think it will be worth my while to do so now, as there will be no doubt fifty copies more wanted? And, if I was to, what about the copies I have issued? Of course, if I was to see one in an illustrated paper or see one copied by some one else, I could not tell if that was one of the first lot I sold before registration, that is what I should feel greatly obliged if you would assist me in; also, if I copyrighted a half-plate print, well, say, and enlarged it, would the enlarged print stand good as the small original as regards copyright, you will do me this favour?"—If you make an enlarged print and work it up, say, in monochrome, and after making it copyright issue copies, you will be protected as regards them. If you make the original also copyright, you will have protection in future. Copies sold—a special private mark might be put on those.

**STUDIO-BUILDING.**—PERPLEXED says: "I am desirous of placing on ground in rear of a detached villa a structure composed of glass and wood supports or a lean-to from back wall of premises, also a glass skylight approach to studio. Should be thankful for information as to the metropolitan law on the subject."—We can only refer you to the Metropolitan Building Acts, which can be had from the Queen's printers, Eyre & Spottiswoode, Great New-street, E.C., but we are not sure that they extend in their entirety to your district. You will, however, have to submit plans to your local authorities and get them approved of before you commence to build. Better consult the district surveyor first.

**VARIOUS.**—"QUANTUM LIBET" says: "1. We find it impossible to use water colours on the P.O.P., and would be pleased if you would kindly say in the JOURNAL the best and where to be obtained? 2. To produce soft lighting on our sitters, which do you consider the best? Some artists use blue lighted studio, others mineral paper, and others frosted glass (our studio has plain glass). Would tinting with a blue paint answer? We have never experimented in this direction, so would like to have a suggestion or two instead of trying what has proved a failure. 3. Where can we learn when the various photographic exhibitions are to be held, and what date work must be sent in by?"—1. There should be no difficulty in colouring P.O.P. prints with water colours. Where is your trouble? The ordinary water colours are used. 2. Either of the methods mentioned answer well, but some prefer one and others another. Some, on the other hand, prefer the plain glass and the judicious use of the blinds. It depends more upon the man than anything else in getting the best results. 3. Forthcoming exhibitions are always duly announced in the JOURNAL.

**PORTRAITURE IN ORDINARY ROOMS.**—CHARLES PARTINGTON says: "I would like to ask your advice about the attic rooms you will notice in the plan below that I wish to make use of for taking portraits, especially busts. I have rapid rectilinear lenses of eight inches and also eleven inches. I would prefer the eleven inch lens for that purpose. Which room is the best for the purpose? I took one in the second room, but there is too much flat shadow, I think. How should I arrange the sitter? How far should the sitter be away from the window, and how far should the reflector be away from the sitter? In taking the bust in the second room, I took the picture from the No. 1 room through the door. In short, kindly advise me as to the best way of getting good portraits in such rooms as these I have at my disposal."—Good portraits, busts, can be taken with the eleven-inch lens with the sitter placed in the No. 2 room and the camera in the No. 1 room. With a little modification in the lighting, the portrait enclosed would have been good. No definite set rule can be given. The best way is to place the sitter at different distances from the windows, and study the effect of the lighting then. When the best effect is obtained, proceed to soften the shadows by arranging the reflector so that there are no harsh shadows. A very little alteration in the arrangement, as we have just said, and the portrait would have been satisfactory.

**AN ASSISTANT'S DIFFICULTY.**—TORQUAY says: "Can you give me a little advice re the following? I was out of a berth, and, in reply to an advertisement in your JOURNAL, I sent photographs of self and wife, references, &c. It was to take management of a branch, to operate and turn out all my own work. Salary, 1*l.* per week, and fifty per cent. on all takings; room, rent, and rates free. I was told rooms were small, but might be made very comfortable. This, of course, was after I had been informed that my specimens, &c., were satisfactory. Well, after arranging for a twelve months' certainty, I agreed to pack up and go. The distance was over 200 miles, and, having furniture, &c., it cost me altogether about 8*l.* Well, on arriving at my destination, I was (my wife more especially) disgusted with the rooms we were expected to occupy, which consisted of two small attics and a kitchen, without a sink or scullery wherewith to carry on the regular household duties of every-day life. Several alterations and additions were suggested, and, when at length we resolved to try it, we were more than horrified to find the place was swarming with bugs and fleas, the former especially. I need hardly say one night was quite sufficient. I acquainted my employer with this state of affairs, and while in my presence he looked at the thing favourably, and seemed agreeable to pay me an additional 7*s.* 6*d.* per week to live off the premises; but, on account of the interruption of some sitters, no final decision was arrived at, and while engaged in operating the governor disappeared, and must have gone on by tram to headquarters. I wrote him asking for something definite, and received a reply to the effect that, as he had no alternative, if I could not live on the premises, would I send in a month's resignation? He felt convinced, after consulting the landlord, that the articles had been contracted from lodgings, removal of furniture, or something of the kind. Now, I know it was not the first, as the lodgings were spotlessly clean, and we had had our furniture removed before without such a thing happening; and, besides, every bit of material was either packed in boxes, wardrobe, or drawers, all fitting very tightly. I know for a fact they are in the walls and crevices. A friend of ours called in before we slept here, and predicted exactly what came to pass. Besides this, we understand that we are not the first who have been taken in with the rooms, but that wise man neither brought his wife nor his furniture, so only had himself to take back. Possibly he lived nearer than I. My employer tells me the landlord (who keeps a jeweller's shop underneath) will hear of nothing other than the operator himself living on the premises, otherwise I could have let the rooms, though, if not fit for me to live in, it is not fit for any one. We are young beginners, and the loss we have sustained to us is very great. Can you advise us what to do? If so, we shall be extremely obliged."—This seems a hard case, but we surmise there is no legal remedy for it. Our correspondent should have seen for himself if the rooms were suitable for him and his wife to live in before he removed into them or accepted the engagement.

## EX CATHEDRA.

ALTHOUGH the Royal Photographic Society will not for some weeks take possession of its new premises at No. 66, Russell-square, W.C., members no doubt will be interested to know that the building is already practically fit for occupation. We have had an opportunity of viewing the house, which has just been passed out of the decorator's hands, and we do not exaggerate in saying that a more suitable home for the Society could scarcely have been obtained. The large, well-lighted, and lofty rooms of the old mansion are admirably adapted for a meeting room, council chamber, library, offices, and the photographic accommodation it is proposed to provide; and it will be found, we are sure, when the first meeting is held, that the spacious building fulfils in an exceptionally efficient way the requirements of a body such as the Royal Photographic Society, many members of which have for years been looking forward to the time when the Society would have a home of its own. That time has arrived, bringing with it as handsome a fulfilment of the aspiration as could be wished. All that remains to be done is the necessary furnishing, which is occupying attention.

WE are extremely pleased to learn that the action we took a fortnight ago in drawing the attention of members of the Royal Photographic Society to the importance of nominating gentlemen to act as Judges at the next Exhibition has been met by the most encouraging recognition. The nominations that have been sent in number thirty-five for the Pictorial Section and nineteen for the Technical, a total of fifty-four as against five and three last year—in all eight, a number which precluded the necessity for a ballot. This year's balloting paper will be issued, in a few days, with the next number of the Society's *Journal*. It is to be hoped that members will freely exercise their right of ballot, so that the men selected for the office of Judge will feel that they possess something of a mandate. In any case it seems assured that the ridiculous state of things which was brought about by members' apathy or indifference last year will find no repetition this.

\* \* \*

NOT the least remarkable feature about the new studios at No. 51, Baker-street, W., which Mr. Alfred Ellis threw open on Thursday in last week to the inspection of a large and fashionable crowd of people, among whom the "professional" element was very strongly represented, is the rapidity with which the house has been put in order. It is a very few weeks since Mr. Ellis was ousted by the railway company from his former place of business in Upper Baker-street, and in that comparatively short space of time the new house in Baker-street proper has been swept and garnished, redecorated, furnished, and made ready for use. The many guests who attended the popular host's "At Home" last week had the run of the house from basement to roof, and saw not the least of those familiar signs of incompleteness and unpreparedness which are usually very apparent when one is invited to inspect a new installation of any kind that has had to be got ready in a hurry. Mr. Ellis is a man of business to his finger tips, and knows the value of being up to date in all that he undertakes.

\* \* \*

BAKER-STREET has been a great photographic centre these thirty or more years past, and Mr. Ellis's new studios, &c., which occupy the whole of the building, No. 51, constitute a

fine addition to the photographic establishments which already adorn that fashionable thoroughfare. In the basement are large developing and negative-stocking rooms, and a "professional" dressing room, in which the members of an Alhambra ballet might almost be accommodated at one time. Indeed, roominess is a very marked characteristic of the suites of apartments Mr. Ellis has at his command here. The ground floor is occupied by the publication department—a very large branch of Mr. Ellis's business—and thence one finds one's way into a prettily decorated region of lounge-come-reception room at the rear. Gaining the studio upstairs, we perceive that it runs from north to south, catches almost uninterrupted light on both sides, the south, of course, being well under control by means of blinds, &c. The length of the studio is about fifty feet; it is about twenty-two wide, and twenty-three or twenty-four high. Truly a noble place, in which, as the phrase runs, the photographer can do almost anything. The reception room, which adjoins the studio, looks out upon the street. A large part of Mr. Ellis's business lies, as of course every one knows, with stage folk, for whose peculiar requirements every facility is at hand. He has absorbed the business of M. Walery, many of whose negatives are in his possession, prints of them being conspicuously shown.

\* \* \*

We must congratulate Mr. Ellis on the elegance and good taste he has brought to bear in the decoration of his studios, heaviness of furniture and darkness of colour having been avoided. You walk through his spacious rooms with a feeling that your surroundings are light, airy, and graceful. It is a fashion in many quarters to look upon portrait photography as on the decline in the business sense. Evidently Mr. Ellis, to judge him by the bold venture he has just made, is not of this opinion, and he assuredly deserves continued success in his new quarters. It should be said that the walls of his galleries are covered with portraits of famous actors, actresses, and society people, so that one feels one is present among many very old friends when one looks at these excellent specimens. Stageland, in fact, is everywhere in evidence at 61, Baker-street.

\* \* \*

MR. GEORGE W. TOTTEM, F.R.P.S., has recently started in business as a photographic dealer at 6, The Boulevard, Balham, S.W., in the centre of a district thickly populated by photographers, chiefly, of course, amateurs, who have early commenced to show their appreciation of the presence of a photographic dealer in this most easily accessible of the great South-western suburbs. The premises occupied by Mr. Tottem are spacious and elegant, the front shop having a refined and saloon-like character, adorned with a good selection of apparatus and many fine enlargements on Eastman papers. The dark room is a model of neatness and efficiency. Throughout his handsome installation Mr. Tottem shows the possession of a thorough practical acquaintance with photography in most of its branches, a knowledge which is freely placed at the disposal of his clients. It is not every dealer who can point to twenty years' practical experience of photography as a recommendation, or produce first-rate results with the apparatus that he sells; but, in both these respects, Mr. Tottem comes out very strongly, and we therefore wish him the success he deserves in his plucky determination to cater for the needs of the growing numbers of amateur photographers in South-west London.

We frequently have the opportunity of "sitting" for our photograph to professional friends who seek an expression of our opinion on their work. The author of the latest addition to an extensive collection of portraits which owe their origin to this cause is Mr. J. F. Habgood, of The Arcade, Boscombe, at which charming health resort we were fortunate in spending last Easter with a friend. The portrait which Mr. Habgood was kind enough to take of us has been pronounced by those most competent to judge as a striking and characteristic likeness; while, for ourselves, perhaps the most favourable criticism we can pass upon it is that we are very pleased indeed with it. Mr. Habgood has two studios at Boscombe, at which he produces excellent work. He is a clever all-round photographer, and, unlike many of his professional *compères*, has a perfect "studio manner," that is to say, he is quick, certain, and happy in posing and lighting his sitters, whom he easily inspires with confidence. The intelligence and skill Mr. Habgood brings to bear in his photographic work is very great, and should one day win him a place in the front rank of portrait photographers.

\* \* \*

THE many thousands of persons in all parts of the world who follow the yearly progress of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC may be interested in knowing that the volume for 1899 is now out of print, and that our publishers are unable to supply further copies. This result, occurring as it does within about three months of the publication of the volume (the largest in point of size and circulation yet issued), touches record in the history of the ALMANAC, and is a circumstance to which we hope we may point with pardonable pride. It attests, in the most eloquent manner possible, the very high degree of appreciation which is widely felt for THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC.

#### PHOTOGRAPHIC PYROTECHNICS.

WHEN the importance of the subject is considered, it may be held as somewhat singular that the question of actinic lights—pyrotechnics, in fact—has hitherto been treated in such a *dilettante* fashion as this has been. A few experimenters, it is true, have taken it up, most of them for trade purposes, but we are without any serious exposition of the theory of action, and the principles governing the application, of quickly burning compounds as a light source in photographic operations. It is perhaps about thirty years ago when the value of these pyrotechnic mixtures for the purpose was recognised, the outcome being an apparatus for burning them well known at the time, Moule's photogen; burning magnesium wire, and, later, ribbon of the same, displaced the first-used materials, and, coming down to a period comparatively recent, magnesium powder became the popular means of producing actinic light. This, of course, was owing to the so-called instantaneous character of the combustion under the particular circumstances under which it was carried out; hence the term "flash-light." It goes without saying that the cause of this quick popularity lay in the innocuous nature and freedom from smell of the products of combustion. It was not so thoroughly understood as it might have been that the composition of the later kind of pyrotechnic mixtures of "coloured fires," including white, had undergone a radical change. In the older mixture the necessary flame background was formed by the

highly dangerous arsenical compounds, realgar and the like; in the newer mixtures this was replaced by powdered shellac, and, when this, at first secret, method was utilised, coloured fires were profusely used in pantomime and other theatrical effects. But the large volume of smoke, not free from odour, evolved in the combustion rendered them useless in dwelling-houses or in studios unless some elaborate contrivance was devised for carrying off these fumes.

Magnesium powder gave off virtually no smell and the "smoke" passed away fairly quickly, but still there was smoke and enough of it to render even magnesium flashlight virtually impracticable in closed apartments. To simplify the operation of burning the metallic powder and to reduce the smoke, it was used so mixed with various chemicals to supply the necessary oxygen that a return to the older methods was in effect brought about, until an unfortunate spontaneous explosion, with its fatal results, of a quantity of this material brought home to its users its essentially dangerous character. "Chlorate of potash," as also permanganate of the same base, grew in favour, owing to the reduced danger attending their employment, and quite lately the value of nitrate of ammonia has been brought prominently forward. It is stated that, when well dried and finely powdered, it gives, mixed with an equal weight of the metal, a quick combustion and a minimum of smoke. It must be remembered, however, that this salt is deliquescent, and hence care has to be exercised both in powdering and in storing the powder to prevent the absorption of moisture. The composition of the very latest varieties of magnesium mixture was given a few weeks ago in these pages; but, as a recent letter points out, they are patented and, of course, not open to the public generally to manufacture, though the ready-mixed patent compositions are now commercially procurable in convenient packages at reasonable prices.

If it be desired to ask what are the requirements of a powder for photographic light purposes, we may say they are ready combustibility combined with freedom from liability to spontaneous combustion, strongest actinism in the light, and the production of a minimum of fumes or smoke.

The question arises, Is magnesium a necessity in these mixtures, or can it be replaced by any other metal? In reply to such question it may be pointed out that it is now some years ago that aluminium powder was recommended as a substitute and had some vogue at the time of its introduction.

The principle governing the selection of the metal to burn is the production of intense heat together with solid particles of matter suspended, as it were, in the flame to act as light radiators. Intense heat is useless till there are particles of matter to be heated to intense luminosity and so radiate actinic light. A parallel to these points is found in the two types of gas flames now in use. In the old kinds of burner the combustion of the gas caused the deposition of particles of carbon which instantly became, by reason of their heat, luminous; in the newer, the incandescent, the whole of the gas with its contained carbon is burnt with a non-luminous flame; the heat is then conveyed to an ingeniously constructed mantle of network of the rare earths. This becomes so luminous when heated that its brightness far exceeds that of an ordinary gas flame. It has, however, been found that the brilliancy of the light is not purely a function of the temperature, it is dependent also upon the nature of the radiator.

The place where experiment may come in with regard to the composition of an exploding compound is, first, the mode of

obtaining the highest temperature of combustion; and, secondly, selection of the best radiator, whether as an added element of the flash powder or as a product of combustion, and the carrying out of a series of trials of various substances would prove most valuable if done in a systematic manner.

In this connexion it may be noted that a valuable paper bearing on this question was recently contributed to a Continental scientific paper, an electro-chemical journal. In it the writer—M. Goldschmidt—points out the enormously high temperature obtained, reaching to about 3000 C., by the combustion of metallic aluminium in powder under suitable conditions. The object of the experiments in this instance was the obtaining heat rather than light, and he obtained his effect in one instance by igniting a mixture of oxide of iron, sand, and aluminium powder by means of a piece of magnesium ribbon inserted in a pile of the powder and lighted. With the means thus roughly indicated we have the bases of experiments, which, fitly utilised, may be capable of bringing the use of what may be termed pyrotechnic compounds into a practicable and scientific channel.

**Platinotype versus P.O.P.**—At a recent meeting of the Leeds Photographic Society, the Rev. J. Beanland, M.A., gave a lecture on the platinotype process, in the course of which he compared the cost of printing in platinotype with P.O.P. The reverend gentleman said: "There was another erroneous impression he would like to correct. It was said that the paper was more expensive than P.O.P. He had gone into the matter carefully, and found that the cost of printing, toning, and fixing four dozen half-plate P.O.P. prints costs about 5s., and, after making allowances for failures, they might reckon on getting thirty successful prints; with platinotype, the same number, half-plate size, with chemicals, costs 7s. 6d., and the average number of successful prints might be put down at forty-five." Now, this argument (unless the reverend gentleman has been mis-reported) will be not a little amusing from its data. Thirty successful prints from forty-eight sheets of P.O.P.—why not four dozen, with the commercial papers now in the market? Again, with the platinotype process, why not also with the Platinotype Company's paper, a like number of successful prints? Where is the photographer—even the veriest tyro—who does not get more than two dozen and a half good prints out of four dozen pieces of P.O.P.? What would a photographer say to his printers if they had forty per cent. of failures with the prints they made on P.O.P.? If the reverend gentleman had qualified his statement by his own experience of the two processes, one might have appreciated it better. It is noteworthy, however, that Mr. Beanland said, in the early part of his lecture, that, "when he commenced the study of photography on the advice of a professional friend, he started to print with platinotype, and he had stuck to it ever since." Hence it may be assumed he has had but a very limited experience with P.O.P. upon which to found his data with regard to the certainty of its working. It seems, therefore, surprising that he should speak so decidedly on the subject. Possibly, as we have hinted before, the Rev. Mr. Beanland has not been correctly reported.

**An Opportunity.**—Just now photographers have an opportunity of securing photographs of St. Paul's Cathedral such as they have never had before. The block of houses between Paternoster-row and St. Paul's-churchyard has been pulled down, and thus disclose a view of the Cathedral from Cheapside that has never been seen before during the present or the past generation. St. Paul's, like most other cathedrals both at home and abroad, is so surrounded by buildings that it is impossible to see them with advantage, let alone to obtain photographs of them, even when the aid of the widest-angle lenses is invoked; therefore, when an opportunity like this occurs, it should be availed of without delay, as the chance is only temporary, and we know that many pictures have already

been taken. It is true that the ground is not entirely cleared, as part of the corner building still remains, but it is only shop high, and as at present there is no offensive scaffolding up to very seriously mar the foreground, no time should be lost. If the photographs be taken from one or other of the first or second floors on the opposite side of Cheapside, the remains of the demolished buildings will not show very offensively in the pictures. From this point excellent stereoscopic views can be obtained.

WHILE on the subject of St. Paul's we may allude to the discussion that has taken place in the daily press of late, and was prominently brought forward in the House of Lords on Friday last, as to the decorations now going on in the interior under the dome to the order of the Dean and "a Committee of Taste." These coloured stencillings have been described by one writer as being "exactly like the colours of an English lobster salad." Others have characterised the embellishment of Wren's masterpiece with the colours as like an attempt to paint the lily. Whenever anything is done with any of our cathedrals there is generally a great outcry from archaeologists, artists, and others; but repairs are necessary and must be made, even if when, as in the case of the west front of Peterborough Cathedral, a partial rebuilding has to be done. The case is different, however, with "embellishments," particularly when they take the form of Byzantine mosaics in a Renaissance fabric. However, it is satisfactory to learn that the Dean and Committee of Taste have suspended the stencilling work for the time being.

**Vanishing Old London.**—Two more well-known buildings though gruesome ones, are to be pulled down. Newgate Prison and the Old Bailey are to be removed. Neither of them is picturesque, but photographs of them will be exceedingly interesting to future generations, and there is no difficulty in securing them now, and for some little time to come, for we learn that the designs for the new Central Criminal Court, which is to be erected on the site of Newgate, are not yet prepared; still, the latter prison is to be pulled down shortly. Photographic interest is frequently not taken in ancient buildings (though this can scarcely be classed as one, for it was only completed in 1782), till they are in the course of demolition, and they are obscured by hoardings, and "posters," and scaffolding. Newgate, as we have just said, is as yet unobstructed in that way at present, though its removal is close at hand.

**Projected Copyright Act.**—On Tuesday, last week, Lord Monckswell, in the House of Lords, presented a Bill to amend and consolidate the law with regard to literary copyright. At the same time he also presented a Bill to simplify and amend the law relating to artistic copyright, and both the Bills were read a first time. The latter deals, amongst other things, with the copyright in photographs, and, from what we learn, as projected, it is more to the advantage of painters than photographers; the latter, as a body, will do well to watch their interests in the matter. Some artists speak roughly of photography, though they are anxious to sell the copyright in their works to large photographic publishing firms. It would be interesting to learn how many of the works in the Royal Academy Exhibition, which opens next week, have been painted partially, if not wholly, from photographs. Many artists who decry photography utilise it largely to aid them in their work, particularly in portraiture, also in landscapes, though they would be slow to admit it.

**The Metric System.**—Another Bill was brought into the House of Commons last week, and read a first time, to amend the law relating to weights and measures. Sooner or later we shall, doubtless, have the metric system universally adopted in this country; but why should photographers wait, seeing the advantage it gives in compounding photographic formulae, more especially those coming from the Continent? One reason why, as we have heard expressed, is that the metric weights and measures are more costly

than the usual *avoirdupois* and apothecaries' ones. That is really not the case, as there is no difference in the price, with the manufacturers, in the cost of measures by the two systems—graduation for graduation. The price is ruled by the number of the graduations. With regard to the weights, if of Continental manufacture, they are really cheaper wholesale. For example, sets of weights from a centigramme to 300 grammes—roughly ten ounces—are supplied wholesale, in a neatly fitted and polished case, for less than 4s. Why, it may be asked, do not photographic-stock dealers make more of a feature of metric weights and measures?

## JOTTINGS.

THE members of the Royal Photographic Society will not be caught napping this year in regard to the election of Judges for next autumn's Exhibition. There is likely to be an extensive list of nominees, and a more or less keen contest on the ballot. This is quite as it should be. Last year just the required number of Judges was nominated by a total of about as many members, so that there was no election. It would have been all the same if a bootblack had been nominated. It cannot be said that last year's jury gave satisfaction with their awards. Judges seldom, if ever, please all parties, but they usually manage not to fall out among themselves. Last year not only were some of the awards very unsatisfactory, but the people who made them did not hit it one with another. One gentleman who then served writes me that he will not stand again because one of his fellow Judges "bossed the job." There should be no bossing of the job this year if members do their duty, and refuse to elect gentlemen to judge the Exhibition of a Society towards which their sentiments are the reverse of sympathetic.

Mr. Bennetto should pray to be saved from his friends. His process was mentioned in two of the photographic papers last week. Mr. E. J. Wall, who certainly knows what he is writing about when colour photography is his subject, contemptuously dismisses the Bennetto process as "the old, old three-colour process which dates from 1861." On the other hand, a writer in *The Amateur Photographer* says it "is certainly a step in advance and involves a new principle in the arrangement of the camera." For the life of me I fail to see how three-colour photography which relies upon carbon printing with coloured pigments for the finished transparency, can be looked upon as a step in advance. It bears a close resemblance to the backward order of progression. But waiving this by no means immaterial point, let us examine the new principle in the arrangement of the camera—the inclination of a red glass at an angle of 45° to the axis of the lens, and the placing of two other plates with a film between them on the top of the camera.

Berthier, in 1895 (*Manuel de Photochromie Interférentielle*, pp. 52, 53), describes a stereoscopic camera for taking the three negatives at one exposure, and two years later White (*THE BRITISH JOURNAL OF PHOTOGRAPHY*, April 16, 1897) patents a camera for monocular work. Both these cameras allow of the "reduction of the size of the camera to that of an ordinary tourist camera," as claimed for that of the Bennetto, and, as the principle he employs differs only in detail from that adopted by Berthier and White, who take the three images at once, the much-vaunted "step in advance" is, I fear, more imaginary than real. A mere matter of difference in construction, the practical value of which remains to be demonstrated, is not the surest foundation upon which to base the deliberate opinion that the Bennetto colour camera "should open up new paths for amateurs and professionals, and . . . prove the foundation of new commercial enterprise and growth." In the writer's own words this is somewhat "hasty" prophecy, I'm afraid.

One or two other references of this writer also invite correction. It is not, as he says, four or five years since the Bennetto "discovery" was announced. The first reference appeared in this *JOURNAL* for July 31, 1896, not three years ago. Again, "the

official and reliable information" about the process was not, as the writer appears to think, published for the first time last week; it all appears in this JOURNAL for December 2 last, nearly five months ago. Then the writer goes on to say, "There is nothing absurd, unscientific, or impossible, in Mr. Bennetto's device, as has been suggested, and, in holding over our comments until official and reliable information became accessible, we had in mind those hasty criticisms in other quarters which may have damaged the commercial reputation and development of the process, to say nothing of the risk which hasty critics run of being brought unpleasantly to book."

Now, I have read all the criticisms that have been delivered on the process, but I do not remember to have seen it described as "impossible." It is certainly "absurd" if it is put forward as a novelty, for three-colour negative-taking and carbon printing in colours were not discovered at Newquay. As to the process, taking it by its inventor's description, being wrongly termed "unscientific," when the writer I am quoting from drops such highly illuminating terms as "red" glass and "greenish-yellow" films, he will inspire some confidence in his ability to defend the Bennetto process as the philosophical outcome of a study of the Young-Helmholtz colour-vision theory, and the Clerk-Maxwell theory of colour sensation, which are the essential roots and foundations of all "scientific" three-colour work. The writer's benevolent solicitude for the commercial development of the process, coupled with his denunciation of hasty criticisms, is funny—very funny.

If the Bennetto three-colour camera and carbon process were entirely new, they might merit the eulogy passed upon them. But they are only new in unessential details—and there's the rub. Of course, you can make very pretty transparencies by superposing coloured pigments in gelatine; indeed, I'm told Mr. Ives worked such a process years ago, only to abandon it. Mr. Ives is a sound, conscientious, and scientific experimentalist, who has abandoned many a process which did not answer the requirements of colour theory. The Bennetto process is certainly colour photography of a kind, but it is not photography in natural colours, or in the colours of nature, such as men like Lord Rayleigh, Captain Abney, Professor Joly, Professor Lippmann, Wiener, Zenker, and the other great theorists would define it. Not by any means for the first time do I say that, so far, Mr. Bennetto has done nothing whatever to satisfy us that he is really in possession of that "jewel" of colour photography he has more than once referred to. And, the mysterious jewel apart, bichromate printing in three colours does not entitle Mr. Bennetto to claim, as he did last January, that he has "solved the problem of colour photography." Not yet, Mr. Bennetto; not yet, if you please!

To "Touchstone": The Salon epitaph is still in MS. But I am tempted to put it in type, for, after a recent whip-round of thirty shillings a head, which the noble Links had to impose upon themselves to make up a deficit, matters Salonic must be getting in a bad way. The next thing we may hear of is the Ring going, hat in hand, to the Photographers' Benevolent Association for a "sub." The P. B. A. has 300*l.* in hand which it does not know what to do with. I shall be pleased to support the Ring's application for assistance; and, to the same end, I will, if desired, raffle the MS. of that epitaph amongst members of affiliated societies at a shilling a head! Meanwhile, my dear Touchstone, you will be glad to know that the R. P. S. is moving into a New Palace of Delight in Russell-square. It is quite a baronial mansion, with a ceiling by Angelica Kaufmann, and other attractions. And all this and more may be had for the inadequate sum of one guinea per annum!

It is refreshing to turn from the untenable claims of *soi-disant* discoverers of photography in natural colours to the extremely interesting paper on the real subject by Professor Wood, of Wisconsin University, which was published in these pages on

April 14. By the beautiful device of superposing a photograph of a diffraction-grating on a glass positive, Professor Wood secures a transparency which reveals natural colours by transmitted light. No more elegant and simple method of obtaining results in colour has yet been published, and it is to be hoped that Professor Wood's work will be taken up and repeated by others. In the way of easily multiplying copies, it seems to have possibilities not possessed by any other method. While on the subject of colour, I should like to draw attention to the fact that the *Optician* is publishing a translation of Wiener's paper on "Colour Photography by Means of Body Colours and Mechanical Colour Adaptation in Nature," a deeply interesting contribution to the philosophy of colour photography which the student should possess.

Specimen thieves, whose wicked ways have recently formed the topic of many complaining communications to this JOURNAL, should make a note of a case mentioned in *Ex Cathedra* for February 17 last (p. 98). A firm was sued for the wrongful detention of specimens, and the plaintiff obtained damages to the pleasant little tune of 75*l.* Operators are frequently very foolish in unnecessarily parting with specimens, or sending them so carelessly packed that there is no possibility of returning them; but cases of real and deliberate detention do occur, so that, where all the facts are known, the precedent I have just quoted may be very effectively played off against an offending party.

COSMOS.

#### FOREIGN NEWS AND NOTES.

**Fat in Gelatine**—Dr. E. Vogel refers to this question in the *Photographische Mittheilungen*, and recommends the use of ammonia to obviate the difficulties brought about by the presence of grease. The collotyper, to his regret, is familiar with the small pits due to greasiness of the gelatine. These produce black spots in printing. It has been recommended to keep the gelatine some time in a fluid state to allow the fatty particles to rise to the surface, and then to draw off the gelatine from below. This is a doubtful remedy, as it only removes the coarser fatty particles, whilst the finer remain distributed like an emulsion in the gelatine. The best means by which the fat may be removed is to treat the gelatine with ammonia, which converts the grease to soap. The gelatine should be dissolved, two per cent. of ammonia added, and the vessel should then be stood for ten minutes in boiling water and frequently stirred. To prevent rapid evaporation of the ammonia, cover the vessel with a sheet of glass, allow the solution to cool down to 50° C., and then add the bichromate. As the gelatine is softened by the addition of ammonia, it is preferable to start with a harder gelatine. Chrome alum should not be added, as it would be decomposed by the ammonia. Gelatino-bromide plates prepared with ammonia show less tendency to pit than those made by the boiling processes, for the reason above stated. In the boiling processes the gelatine might be treated with ammonia to remove the grease, and then neutralised, or rendered slightly acid, with nitric or glacial acetic acid.

**Transferring Process Negatives.**—The *Photographische Chronik*, in replying to an inquiry, discusses the question, Why process negatives tear and strip more readily than line negatives. The tearing may depend upon the larger number of acid and alkaline baths which are used in process work, and, combined with copious washing, they may loosen the film. But the principal factor is the deterioration of the elasticity and flexibility of the film by the more copious and compact deposit of metal in the process of intensification as compared with line negatives. This is very evident if a line negative, intensified with pyro and silver, is compared with a process negative intensified with lead or bromide of copper. A good collodion will stand much, but many collodions used for process work are far more porous than those used for line work. Tearing of the film in stripping is best avoided by adding acetic acid to the bath, and using a thin, flexible paper, which has not been over-sized, as temporary support. But, when the transfer has been successfully accomplished, how is it that process negatives strip from the glass support more readily than line negatives? This is due to the heavier deposit of metal in the process of intensification. It often imparts a perceptible relief to the image. The film is then coated with rubber solution and plain collodion, but no fusion with the collodion of the negative occurs. After the negative has been reversed it only

adheres to the glass by the dots formed by the screen, whilst in the case of the line negative considerable areas adhere. This is proved by the fact that only the high lights, in the process negative, detach themselves from the glass.

**Parallelism in Copying.**—Herr Gerstenbrandt, of Gratz, recommends the following method: Set up the camera in front of the plan, or map, to be copied, and adjust it with a spirit level. Fix a compass to a square block of wood, bring one of the edges in contact with the object to be copied, and note the exact position of the compass. Then apply the same edge of the block to the focussing screen, and turn the camera on the screw, so that the needle of the compass assumes the same position as before.

**Bismarck's Photograph.**—The photographers, Wilcke and Priester, who photographed the late Prince Bismarck, have been sentenced to imprisonment for six and three months each, respectively, for illegally entering the room in which the body of the late Prince lay. The keeper, Spörcke, who assisted them to enter by the window, has also been condemned to five months' imprisonment. We do not think any sympathy will be felt for the perpetrators of this outrage on the feelings of the relatives of the deceased statesman.

**Peroxide of Hydrogen and Photographic Reliefs.**—The *Photographisches Wochenblatt* draws attention to a paper read by Dr. Andresen before one of the Berlin photographic societies. One volume of peroxide, in concentrated aqueous solution, evolves, when boiled, 475 volumes of oxygen. It is therefore an oxidiser. But, in consequence of the peculiar condition in which half of the oxygen exists in combination with oxygen in the opposite condition, it may also be used as a reducer. For instance, peroxide of hydrogen reduces silver oxide to silver by affinity of the oxygen of the silver oxide for the excess of oxygen in the peroxide of hydrogen. But,

since diamine,  $\begin{array}{c} \text{NH}_2 \\ | \\ \text{NH}_2 \end{array}$ , and hydroxylamine,  $\begin{array}{c} \text{NH}_2 \\ | \\ \text{OH} \end{array}$ , are developers, it also seems

probable that peroxide of hydrogen  $\begin{array}{c} \text{OH} \\ | \\ \text{OH} \end{array}$  is also a developer. This

is actually the case if the peroxide of hydrogen is used in alkaline solution, by which means the silver bromide is predisposed to form silver oxide. Peroxide of hydrogen acts differently in acid solution. In this case the metallic silver is converted to silver oxide, and is dissolved by the acid. It therefore becomes a reducer. But it also dissolves the gelatine that incases the particles of silver, and a negative relief of transparent gelatine is thus obtained, in which the highest lights form the deepest depressions. This may be important in photo-mechanical work, and a patent has been applied for.

**The Action of Light at Low Temperatures.**—Messrs. Lumière gave an account in the *Bulletin de la Société Française* of some experiments made for the purpose of ascertaining if the action of light on the silver haloids is physical or chemical. As it is generally admitted that chemical action is slower at low temperatures, a gelatino-bromide plate was plunged in liquid air. Part of it was allowed to emerge, and was exposed to light. It was found that short exposures did not produce any appreciable effect. The portion of the plate immersed in liquid air was reduced in temperature to  $-191^\circ \text{C}$ . Light action could be obtained by long exposure, and extra-rapid plates were found to require 50 to 400 times normal exposure at  $-191^\circ \text{C}$ . Light action was further reduced at the surface of the liquid where evaporation produced a still lower temperature. It was also observed that the same phenomena were produced when the plate was not in actual contact with liquid air, and that the latter absorbed chemical rays but very slightly. The plates did not suffer deterioration by exposure to liquid air, and regained their sensitiveness at the ordinary temperature. It was found that the latent image could be exposed to  $-190^\circ \text{C}$ . without impairing capacity for development when the normal temperature was restored. Refrigeration was, therefore, the sole cause of the want of sensitiveness, which tends to prove that the latent image is the result of chemical decomposition. Other light-sensitive materials, such as citrate of silver paper, bichromated mucilages, &c., also remained unaffected by light at about  $-200^\circ$ . Although chemical action is no longer manifested under these conditions, it is not the case with all phenomena produced by light, such as phosphorescence. Sealed tubes of barium, strontium, calcium, and zinc sulphate were heated until

every trace of residual phosphorescence was removed. These tubes were plunged in liquid air in the dark, and, when reduced to a temperature of  $-191^\circ \text{C}$ ., they were exposed to sunlight, electric light, and X rays. Upon withdrawing the tubes in the dark, they became luminous as the temperature rose. It may therefore be concluded that light is active and is stored up at  $-191^\circ \text{C}$ ., but its manifestation is suspended until sufficient heat is restored.

#### THE FUNDAMENTAL PRINCIPLES OF PHOTOCHROMY.

IN a paper on "The Application of the Diffraction-grating to Photochromy,"\* I have briefly sketched the fundamental principles of heliochromy upon which a proper classification depends. I shall now enter more fully into the matter.

The word "indirect" applied to a photochromatic process is obviously very vague, and leads to confusion between such optical processes as those of Ives and Joly, and chemical processes such as one of Graby's methods referred to in the former paper. The real distinction between the two principles, that one depends on the accepted theory of colour vision while the other does not, does not convey a precise notion to any one who is not tolerably well acquainted with the subject of colour vision and the origin and development of photochromatic methods.†

It is, perhaps, natural for such a person to attempt to discriminate between the two fundamental methods by noticing that the known composite processes depend upon colour screens for their effect, while the direct processes do not. It is, however, conceivable that a direct process—one that does not depend upon any particular theory of colour vision—should make use of screens to produce the effect of colour.

If a slit be illuminated and photographed by a model "prismatic camera," the image on the sensitive plate would consist of one or more bands according as the slit was illuminated with monochromatic light or not; in fact, the same kind of effect would be obtained as that shown on the corona photographs obtained by Sir Norman Lockyer with his prismatic camera. It is easy to imagine that a positive from this banded negative, when backed with a screen coloured and graduated like a spectrum and viewed through the prism, could be so illuminated that the colours should be recombined and the eye should see the slit in its natural colour. Of course, it is extremely doubtful whether such a process could be of any practical use, as obviously the object must be very narrow.

In my former paper Captain Abney was mentioned as dividing processes into "indirect" and "direct." I find, however, that he apparently prefers the divisions "colour photography" and "photography in natural colours," respectively.‡

"It may be said that any feasible theory of colour vision lends itself to the success of colour photography, whilst it requires no theory to take a photograph in natural colours."

The distinction between "colour photography" and "photography in natural colours" as terms is somewhat subtle, but Abney's definition undoubtedly distinguishes what are, perhaps, most correctly called the "composite" and "direct" processes in their fundamental points; but:

"Evidently these (Lippmann's) photographs do not fall under my definition of what is photography in natural colours."

"Photography in natural colours, according to my definition, is photography in pigments."

Abney here makes a restriction which is not even implicitly contained in his first definition; but, accepting both definition and restriction, Lippmann's process, although it is a direct way of producing photographs in natural colours, is not "photography in natural colours." This would be a contradiction of terms if "photography in natural colours" were not simply a name of a class of process to which Lippmann's method does not, according to Captain Abney, belong. Obviously almost any other word would have answered this purpose, and would have been less misleading.

The classification, then, according to Abney, in terms which, I think, are less misleading, is as follows:—

1. Composite processes (which depend on some theory of colour vision).
2. Direct pigment processes (colours due to absorption).

\* THE BRITISH JOURNAL OF PHOTOGRAPHY, April 14, p. 232.

† En passant, it may be remarked that this shows the hopelessness of attempting to expose the subject of heliochromy in the way that is unfortunately almost always done in the case of other sciences (mathematics, notwithstanding the fact that its development is very like that of a physical science, has been the worst treated in this respect), that is, starting from "definitions."

‡ See for example, Abney "The Scientific Requirements of Colour Photography," being the sixth Robert Boyle Lecture delivered before the Oxford University Junior Scientific Club, on June 1, 1897.—*Journal of the Chemical Society*, June 1897, 23 pages. (Henry Frowde). The quotations are from pages 1, 22, and 21.

3. Direct processes of which the colours are due to other causes, such as interference.

The notable point in Abney's classification is the separation of 2 from 3. Bequerel's results were certainly due partly to interference, and that any direct pigment process does not depend on "position of particles" as influenced by wave-length, apart from other properties of light of different colours, is *a priori* so extremely improbable that such a view cannot be accepted without the very strongest evidence. The evidence is at present by no means very strong, and wholly experimental; there has been no serious attempt to raise it to the theoretical state; in other words, to give a rational explanation of it. On the other hand, the Lippmann, or rather the Zenker-Rayleigh, theory affords a theory which is easily conceivable and is capable of mathematical treatment.

PHILIP E. BERTRAND JOURDAIN.

#### NEW MODE OF CHLORO-PLATINITE OF POTASSIUM MANUFACTURE.

The *Chemical News* has an extract in full from the Bulletin of the French Chemical Society of a paper by M. Vèzes upon the production of this salt, so important in the platinotype process. M. Vèzes' process is considered by the author to be much superior to methods hitherto employed. Chloro-platinate, made in the usual manner, is suspended in a quantity of water insufficient to dissolve it even when warm (1 litre per 100 grammes of chloro-platinate, for example; there would be no inconvenience in even reducing this quantity of water). We add one molecule of neutral oxalate of potassium for each molecule of the salt (say, 37 grammes of crystallised oxalate  $\text{CO}_2\text{K}_2\text{CO}_3\text{K} + \text{H}_2\text{O}$  per 100 grammes of chloro-platinate), and heat to boiling. The oxalate dissolves and reacts on the dissolved part of the chloro-platinate; it gives off carbonic acid gas, and the solution, at first a deep yellow, becomes red. The chloro-platinate then gradually dissolves, passing to the state of chloro-platinite, and finally, after the lapse of several hours, the whole is dissolved; the deep red liquid, on cooling, deposits perfectly pure crystals of chloro-platinite. The weight of the crystals thus obtained by the single operation naturally depends on the more or less concentrated condition of the liquid during ebullition; with a convenient concentration it may be more than eighty per cent. of the theoretical weight of the chloro-platinate employed. By the addition of alcohol to the mother liquor it is easy to precipitate almost the whole of the remainder of the salt. To sum up, the preparation of chloro-platinite of potassium may be easily effected by the direct reduction of the platinite salt, held in suspension by boiling water, by means of an equivalent quantity of neutral oxalate of potassium.

#### SOLUTIONS OF ALKALINE CHROMATES.

Now that the carbon process is coming so very prominently forward in connexion with ozotype, Mariotype, and other more or less "up-to-date" methods, it may not perhaps be amiss to call attention to a circumstance that is to a very large extent overlooked by occasional workers whom it most materially affects, if not perhaps also by those who are more regularly engaged in its working. We allude to the fact that solutions of the alkaline chromates, more particularly the bichromates in the pure state, *i.e.*, in the absence of organic matter, are practically, if not absolutely, insensitive to light, whereas the presence of a comparatively minute proportion of any of the usual organic constituents of paper or tissue renders them not only slowly sensitive to light, but also liable to spontaneous reduction in the dark. This means in the first place, of course, that whereas a sensitising solution that is fresh will keep indefinitely, after it has once been used, it begins to deteriorate rapidly, losing the bright, clear, orange tint, and gradually acquiring the smoky brown shade that tells of decomposition; hence, in the first place, a solution once used should never be poured back or mixed with fresh "stock."

It is not only that this partly deteriorated solution is robbed of some of its latent energy, but it actually acquires new properties not dissimilar from those of old sensitised tissue as compared with fresh. The same changes that occur in the tissue itself go on in the same manner, but perhaps more rapidly, in the solution, and, if the latter be of the semi-discoloured description, its effects in sensitising will be tantamount to the production "right off the reel" of a tissue three or four days old. This fact has long been known and utilised for the purpose of obtaining soft prints without the trouble of waiting for the tissue to mature, and many special additions, such as soap, sugar, glycerine, alcohol, and other

substances have been recommended to be made to the sensitising solution with that object in view. But, though the fact may be utilised for practical purposes, it is just as well to keep it clearly in mind, otherwise its possible advantages may be secured when they take anything but a beneficial form.

The different substances exercise widely different effects, though more in degree than in character. A soft gelatine will dissolve more freely in the sensitising solution in warm weather than a hard, and may naturally therefore be expected to lead to more rapid decomposition. Glycerine, sugar, and soap, all familiar constituents of "tissue" as met with in commerce, all have their individual action, while a very small proportion of alcohol will, in a short time—sometimes only a few minutes—completely rob the solution of all sensitising action by the entire reduction of the chromic salt. Bearing these facts in view, the old plan of sensitising and resensitising in the same bath would seem to be the very worst possible to adopt, and nothing short of freely brushing or sponging on to the tissue itself and removal of the surplus by squeezing would appear to offer satisfactory results.

#### COMBINED TONING AND FIXING.

At the London and Provincial Photographic Association, on April 20, the question of Mr. E. Banks' criticisms of Professor Burton's recently published formula for combined toning and fixing again came up, some idea having taken root that the same was a reflection upon the permanence of the combined gold bath and upon gold toning.

Mr. Banks made it clear, however, that this was not his intention. The matter of permanence was a relative question, and he would certainly not assert for a moment that any form of silver print was permanent. His advice amounted to this, that, seeing that gold was wasted in a combined bath, it would be more economical to omit it altogether. Hypo, in the presence of lead and many other substances, would tone the print to any colour desired, with no diminution in permanence, compared with gold-toned prints.

Mr. R. P. Drage avowed a sympathetic regard for the combined bath. He had used it as far back as the time of the introduction of Aristotype paper, and had prints toned in such manner by formulae not materially different from those of the present time, which did not, by signs of deterioration, encourage him to regard doubtfully the value of the combined bath. He was also loth to look upon gold, the photographer's old friend, as an unnecessary substance in toning operations.

The Chairman instanced prints on Alpha paper, and said that he did not find that hypo would tone them alone. The addition of gold, however, at once set up a toning action. He had prints of this sort, nine years old, but no change had occurred in them.

Mr. W. Thomas believed that a large share of the trouble which arose with prints made by the combined bath was to be traced to the fact that the prints were often imperfectly fixed. As soon as the toning was apparently done the print was removed from the bath, when perhaps it was far from fixed. He instanced the case of a picture which was required in a hurry for illustrative purposes and had to be printed off without loss of time. This was done, the print stuck in a combined bath until fairly well fixed, washed for half a minute under the tap, dried, and mounted. Contrary, however, to what he imagined would be the fact, this print, when seen some time after, was better than many which had had the maximum of attention devoted to them.

The Chairman agreed, saying that the same applied to plates as well as papers, and speaking of imperfect fixing as one of the greatest evils to be contended against.

Mr. Thomas showed a couple of negatives afflicted in a peculiar manner. He was using a hand camera blessed with a shutter working far too quickly, and this, combined with the further fact that he was exposing on a very dull day, resulted in some plates which he knew were much under-exposed. He took rodinal (one in sixty) and left the two plates shown standing upright in a tank for ten hours (all night). In the morning he found them affected with an appreciable silver deposit and reversal in the shadows.

The Chairman recommended friction with turpentine or spirit as sure to remove the deposit. It was something like what occurred with a developing solution in an over-alkaline condition.

Mr. Thomas said it was interesting to observe that, despite the long time of development, there was no sign of granularity, or of uneven action or stain.

Mr. Lewis Madland showed some slides of Stockholm, visited in 1885, and gave a few interesting particulars of his stay in the Swedish capital, which somewhat resembles Venice in its position on many islands, being indeed called the Venice of the North.

Mr. Freshwater showed a Lumière colour transparency, made on the multiple-stained-film principle. Some jewels in one of the pictures were wonderfully well rendered and attracted special attention.

Mr. H. O. Rapson contributed some early slides of Gloucester Cathedral, St. Paul's, the Houses of Parliament, and other places, and, with the other exhibitors, was accorded a hearty vote of thanks.

\* See this JOURNAL, p. 232.

## PHOTOGRAPHY AND THE FUTURE OF ILLUSTRATED JOURNALISM.

COMMENTING upon an article by Mr. C. K. Shorter on Illustrated Journalism, which appears in the April *Contemporary*, the *Pall Mall Gazette*, asks: "What is to be the future of illustrated journalism in England? Is Mr. Clement Shorter wise in predicting that the earlier years of next century will see an illustrated *Times*? Is it true that the future of the black-and-white artist who devotes himself to the 'news block' is 'absolutely assured'?" These questions are of greater moment to the art student to-day than possibly the public imagines.

"Judging him strictly on his record," proceeds our contemporary, "Mr. Shorter has been himself—perhaps of necessity—an upholder of the photograph as against the artist in illustrated journalism. He does not believe that there is any 'overwhelming popularity attached to the pen-and-ink drawing, however intrinsically artistic.' He has more than a lurking sympathy for the 'accomplished journalist,' who prefers a photograph of a house to the most finished drawing by an artist of repute, though why he should confine himself to 'a house,' and not include also a horse, or a dog, or a man, will pass the comprehension of most people who have given a moment's study to the point. It is clear, therefore, that, if the future is to see a conflict between art and photography, Mr. Shorter, who is responsible for the art conduct of one of the great illustrated papers, is prepared to range himself on the side of photography.

"The question, then, for the journalistic artist to consider is, How far can the camera supplant him, and where exactly lies the dividing line between the things which the camera can, and cannot, do for the illustrated paper. Were the point decided on artistic grounds alone, the camera would be ruled out of court, for photography never was art and never will be art—is, indeed, getting further away from the artistic basis with every new 'fake' that is invented. But the public loves the snapshot and never questions its accuracy. Many people who are comparatively sane on other subjects have been known to prefer it to the work of the artist. It is, therefore, useless, from a business point of view, to fight the camera on its own ground. Fortunately, that ground is more restricted than Mr. Shorter seems to imagine. The photographs of the late Spanish-American War and of the operations in the Soudan, for example, have proved conclusively that the camera is no good at all on the field of battle. It minimises the enemy, which is a fatal error unknown to the old artist-correspondent, who never failed to cumber the foreground with the bodies of the foe! But, worst of all, it absolutely ignores personal valour, or depicts it in so tame a light that the spectator is left stone cold. In the matter of general news it is no better. Photographs of the late fire at the Windsor Hotel, New York, show us an empty street with a puff of smoke on the house-tops, and one or two firemen standing placidly on a ladder, for all the world as though they were being photographed. For action of any kind the camera is impossible, not alone because it lies, but also because it can never be used at the critical moment. It is only in the presentation of inanimate things that it can be of solid use, and, alas! its inanimation already rests heavily upon the English illustrated newspapers. In the old time one found the news of the day transfigured by the bright intelligence of the artist, quick to seize the essentials only; to-day one finds the pages black with unintelligent photographs, each a mere accumulation of irrelevant and dead-alive details, hopelessly out of proportion to the facts which they would chronicle. Let the photograph be kept in its place as the recorder of interiors—even of buildings; let it by all means give us pretty faces, largely doctored by the man behind the screen; and let it, if it will, depict for us all the other things which do not depend upon living impulses or accuracy of detail. But beyond these limits the artist will remain supreme, and the public will learn to respect him and call for him more and more as art knowledge spreads, and as the appreciation of art becomes a real influence and not merely a fashion, as it is at the moment."

## AN "IMPROVED" GELATINE EMULSION.

HERE MAX PETZOLD, of Chemnitz, proposes the addition to gelatine emulsions of developing substances, so that after the exposure of the plate all that is necessary to produce the image is the application of an alkaline solution. We give Herr Petzold's ideas in his own words, but we have little or no faith in their practicability:—

"If reducing substances be added to a bromide or chloride of silver emulsion ready for running or coating, the emulsion is decomposed on drying, in consequence of the energetic tendency to oxidation of the developing substance.

"In order to avoid this, the simultaneous addition of sulphite of soda is proposed, but this is a failure owing to its also being exposed under certain circumstances to very energetic oxidation, that is to say, it is very easily decomposed, because sulphite of soda in and of itself has an alkaline reaction whilst the reduction chemicals are only oxidised in this (alkaline) solution. If this easy oxidation of sulphite of soda could be avoided, the oxidation of the developing substance in the emulsion could also be avoided. This is easily attained if, in place of sulphite of soda, bisulphite be employed, which is only slightly constant and decomposes into sulphite and sulphurous acid. The sulphurous acid thereby released prevents in

*statu nascendi* the oxidation of the resultant sulphite and also of the developing substance, whilst, on the other hand, the silver salt is guarded against reduction in the emulsion. These appearances are also assisted by the acid reaction.

"The same result is attained with the use of acids in the presence of or without sulphite of soda instead of bisulphite. The sulphite of soda is then converted into a soda salt of the actual acid employed, whilst sulphurous acid is released.

"The process which forms the object of the present invention allows of sensitive dry plates and papers being produced, the emulsions of which contain developing substances and for the development of which only alkaline solutions are necessary.

"The following is an example of one means of carrying out this invention. 300 grammes of developing substance, such for instance as hydroquinone, pyrogallol acid, eikonogen, para-amidophenol, glycin, metol, or other suitable reducing substances employed for photography, are added to 10 litres of emulsion ready for use, the said reducing substance being in turn treated up to twenty per cent. of its weight with an acid sulphite or with sulphite of soda and organic acids which are thoroughly well stirred, poured out and allowed to dry."

## THE MAKING OF MIRRORS.

MIRRORS were formerly produced only by covering one side of the glass sheet with a coat of tin amalgam. Such mirrors are still being manufactured, the coating mixture consisting of from 20 to 25 per cent. of mercury. The old process, however, is now being largely replaced by silvering. The mercury process is highly injurious to the health of the operatives, as the working rooms quickly fill up with poisonous vapours. The silvering method, therefore, has become a blessing to the mirror-makers. It is true that silver mirrors, owing to the thinness of the metallic coat, are not as lasting as the old mercury mirrors, and their sensitiveness to air containing hydrogen sulphide is also somewhat awkward, but for protection from the latter the metal coat is covered with varnish, and, besides, they can be produced cheaper than mercury mirrors, and there is a smaller loss of light. The loss of light with mercury mirrors amounts to 33 per cent., while with silvered mirrors a loss of only 7 per cent. is suffered. For the better qualities of silvered mirrors, glass as colourless as possible, either plate or blown, but well levelled, is used. The light is reflected from the metal surface, that is, from the reverse side of the glass. Should the silver shade slightly into yellow, this shade can be neutralised by using slightly bluish glass.

Silvering and gilding of glass is based on the reduction of the dissolved metals by organic substance. The reduction of a silver-bearing solution by the action of an organic substance can be demonstrated on a small scale if a solution of nitrate of silver in distilled water is heated to boiling and mixed with a solution consisting of one part of grape sugar and eight parts of distilled water. The mixture instantly becomes dim, and in a short time the silver is precipitated in the form of a fine powder on the bottom of the vessel, which, if of glass, is covered with a yellowish-white coat of metallic lustre. The beauty of the metallic covering depends upon the careful preparation of the solutions. In a general way a solution of nitrate of silver containing an alkaline reducing agent is poured on the glass sheets, which, after standing in the cold for a short time, is covered with a firmly adhering coat of silver. As reducing agents there are used pure grape, starch, or milk sugar, and caustic soda or potash, sometimes tartaric acid and ammonia. By pouring the solution on the glass, however, air is often entrained, causing blemishes in the coat. To obviate this, the following process is recommended by *Neueste Erfindungen und Erfahrungen*: The sheet of glass to be silvered is placed in a box made of glass or porcelain, and somewhat larger than the glass sheet, the opposite edges of the sheet resting on two cross bars of glass or porcelain. The side of the sheet that is to be silvered is turned downward. Then the silvering solution is poured into the box until its surface just reaches the lower surface of the glass sheet which has previously been cleansed with a dilute potash solution and rinsed with distilled water. The silver is soon precipitated on the glass. The longer the contact, the thicker the coat. The sheet is then taken out of the bath, the coated surface rinsed with distilled water, dried at ordinary temperature, and finally coated with varnish.

For gilding, three solutions are required, one being metallic gold in aqua regia (1 part of pure nitric acid to 3 parts of pure muriatic acid), the other consisting of caustic soda in distilled water, and the third being the reducing solution composed of starch sugar, dissolved in distilled water, alcohol, and aldehyde. The process employed for gilding is otherwise the same as for silvering.

## THE JOLY PROCESS: FURTHER IMPROVEMENTS.

DR. JOLY has made some further improvements in his process of colour photography, which he describes in the Patent specification:—

"In my Patent, No. 14,161, 1894, I describe a process of colour photography in which the image is subdivided into minute linear areas overlaid by similar areas in certain transparent colours. My present invention relates to a mode of obliterating the linear nature of the image or rendering this linear character less conspicuous.

"To this end I superimpose upon the system of linear image overlaid by linear colours a minute linear or other pattern in a transparent medium, such as glass, gelatine, celluloid, &c., this pattern being in relief and depression in the transparent medium and not consisting of opaque or clear areas. Thus, in the case in which this transparent pattern in relief is linear I arrange that the lines of this pattern shall cross the lines of the image obliquely or otherwise. The effect is to break up the linear image and still preserve its full transparency or almost so. This result is due to the refraction of the rays passing through the transparent pattern.

"The transparent pattern may be borne or impressed on the reverse side of the transparent plate carrying the colours, or it may be borne or impressed on the reverse side of the plate carrying the positive photographic image, or upon a separate transparent plate, which may be affixed to the finished picture or attached to a stand upon which such picture is viewed, or placed in the carrier of a projecting lantern.

"In order to produce such transparent linear patterns in relief I may proceed as follows: If it is desired to impress the pattern on gelatine, the glass or celluloid support is coated with bichromatised gelatine and then exposed to light beneath a screen having the required pattern in opaque and clear, whether a linear or other pattern. Thus, a Levy screen may be used. After exposure, the shaded parts are removed by solution in the usual manner. The required pattern now remains. If it is desired to produce the pattern in glass, the glass support, treated as above, is further treated with aqueous solution of hydrofluoric acid for a short time and then scrubbed to finally remove the gelatine. The pattern now appears on the glass.

"The pattern may be produced in other ways, as by casting the transparent material in a mould having the required pattern in relief; by coating with a greasy varnish, removing this in a linear pattern by aid of a graver or comb, and then etching with acid or otherwise.

"The transparent pattern acts best when raised or depressed in forms which in cross section are lens-shaped or rounded. In the mode of procedure described above for producing the pattern by etching on glass, this result is brought about by the graduated action of the acid through the gelatine. To this end, also, alight separation of the Levy screen and the gelatine when printing may in some cases be advisable."

The following are Dr. Joly's claims:—

1. The combination of a minute transparent pattern, linear or other, in relief and depression in a transparent medium, with a linear image in colours, so as to refract the lines of the coloured image, and thereby reduce or annul the linear appearance of the latter.

2. The combination of a minute pattern, linear or other, in relief or depression, on a transparent medium with a transparent linear image in colours, and either carried on the reverse of the screen bearing the colours, or on the reverse of the positive image, or on a separate plate affixed over the picture or temporarily applicable thereto.

3. The combination of a transparent plate, having a minute pattern raised or depressed on its surface, with a stand for viewing transparent photographs, or with a carrier for projecting the same by the aid of a lantern.

#### PLATES FOR PHOTO-MECHANICAL PRINTING.

The invention for the purpose is thus described by the author, Mr. Alfred Henley:—

"I take a sheet of lead, most conveniently, perhaps, of as pure a quality as may be reasonably possible or can be readily gotten, and therefrom I make a plate of the desired size and shape, preferably very thin (say about from  $\frac{1}{16}$  to  $\frac{1}{8}$  inch in thickness, and the surface thereof can preferably be made in any ordinary and appropriate manner as smooth and plane as may be practically possible or can easily be effected. This plate is placed in a suitable bath, wherein soda has been dissolved in water in about the proportion of 1 ounce soda to 1 gallon water, which bath is, by any convenient means and appliances, heated up to the boiling point, and is kept at such temperature (or thereabouts) while the plate is immersed therein for the space of about half an hour. The plate, by any customary means, is then caused or allowed to dry, when it is thoroughly washed with liquid ammonia, of a strength of about '880, and is again caused or allowed to dry, and then can conveniently be warmed, as is customary.

"The plate then, in any ordinary manner, is coated with the sensitive film, which can, when desired, be made as is usual in this class of photographic work, but the film that I especially and preferably use is composed of the following ingredients, namely, gelatine, bichromate of potash, and water, in about the following proportions, that is to say—1 ounce gelatine and 180 grammes bichromate of potash to 8 ounces of water, which are duly mixed and treated as is customary, and then applied on and to the plate in such quantity and to such thickness as may in each particular case be desired. Then the plate so coated is dried in any ordinary drying oven or other appropriate apparatus at a temperature of about 80° F.

"This sensitive plate can be exposed to light under any ordinary photographic negative as is customary, and during and after such exposure can be treated in manner as is an ordinary colotype or other similar plate and with similar appliances and substances, as may be

desired or necessary and may be customary, until it is ready for the next stage of its treatment.

"This stage consists, as is customarily the practice, in treating the surface with an 'etching solution,' but the 'etching solution' that I use is composed of the following ingredients, namely, liquid ammonia of a strength of about '880, glycerine and water in about the following proportions, that is to say,  $\frac{1}{2}$  ounce ammonia and 6 ounces glycerine to 4 ounces water. This 'etching solution' may be applied to, and used with and on, the surface of the plate in any ordinary manner, where, and how, and when, and to what extent may be necessary or expedient in each particular plate as is customary in this art.

"The face of this plate so prepared can then be treated with transfer ink in any ordinary manner, whether by rolling such ink thereon, or otherwise, when transfers can be taken therefrom in manner as is customary, and as may be convenient and suitable in and for each particular plate, and such transfers can be used in the ordinary manner in and for their required and customary purpose.

"The consequence of making and treating the plate in manner aforesaid, and of and with the particular materials hereinbefore mentioned, is that a 'grain' or a 'texture,' or the like, is produced on and in the film, which therefore has a surface very different from the ordinary surface on the ordinary plate; and it is this 'grain,' or the like, which, contrary to the usual procedure, allows a transfer to be taken from this plate, and then to be placed and used with acceptance directly on the stone or other surface for printing purposes as is desired.

"The particular 'grain' or 'texture,' or the like, on and in any particular film can be varied by varying the temperature at which the plate carrying the same is dried. If such temperature is lowered below the 80° F. aforesaid, by, say, about 5°, or even 10°, then the 'grain,' or the like, will be proportionately larger, coarser, or more open; while, if such temperature is raised above the 80° F. aforesaid by, say, about 5°, or perhaps even 10°, then the 'grain,' or the like, will be proportionately smaller, finer, or closer."

#### RECENT IMPROVEMENTS IN PHOTOGRAPHIC LENSES.

HERR E. LEITZ.

A DOUBLE lens has been used, in which the crown glass has stronger refractive power than its attendant flint glass, the crown glass is biconvex and the flint glass biconcave. This double lens enables a high astigmatic correction to be made, and this has been recognised and led to a further form of lens, in which astigmatic, spherical, and chromatic correction has been so made in each of the triple lenses that either of the latter can be used alone as a photographic objective.

Experiments have shown that the spherical correction was so far behind with regard to the importance of the astigmatic correction that objectives in which the rays falling in an axial plane were brought into conjunction could only be used over about one-third of the theoretical opening. This disadvantage in the lighting power of the objective is attributable to the

fault of astigmatic correction, and a subsequent computation of the rays which do not fall in an axial plane has confirmed this proposition.

The influence of these unaxial rays, which increase with the enlargement of the opening of the objective, pointed the way to the construction of an objective in which the number of the astigmatic correction members exceeded that of the spherical correction members.

Such an objective is illustrated in the annexed drawing:—A and B are two biconvex lenses turned, respectively, towards the object and towards the image. The objective as a whole consists of two unsymmetrical members, of which that marked I, towards the object, consists of three parts, namely, a biconvex lens, a, a biconcave lens, c, and a meniscus, DE. The other member, marked II, turned towards the image, is a dual comb-

bination, and consists of the biconvex lens, *a*, towards the image, and the less refractive biconcave lens, *w*.

The two biconvex lenses,  $L^1$ ,  $L^5$ , which are more refractive than the following biconcave flint lenses,  $L^2$ ,  $L^4$ , give the astigmatic correction. The curve,  $n^3$ , gives the spherical correction as in the cemented curve of an applanatic lens. The inner member is a meniscus of crown glass of less refractive than that of the flint glass lens cemented to it.

As this radius is the only means of correction of spherical distortion, neither the triple nor the dual combination can be used alone, but the combination of the two must be looked upon as a single system.

As an example of an objective with the above-described properties, a system of focal length 240 mm. and an opening of  $f/8$  would have the following measurements:—

$n^1$ 44.3 mm.	$n^5$ 39.0 mm.
$n^2$ 70.7 "	$n^6$ 85.0 "
$n^3$ 17.1 "	$n^7$ 43.0 "
$n^4$ 45.1 "	$d^4$ 2.5 "
$d^1$ 7.1 "	$d^5$ 10.0 "
$d^2$ 2.0 "	$\Delta$ 13.7 "
$d^3$ 4.8 "	
$L^1 = L^5$ $n b$ 1.6112	
$n f$ 1.6187	
$L^2$ $n d$ 1.5514	
$n f$ 1.5587	
$L^3$ $n d$ 1.4967	
$n f$ 1.5020	
$L^4$ $n d$ 1.5366	
$n f$ 1.5444	

The claim is for a photographic objective corrected for spherical, stigmatic, and chromatic errors consisting of two unsymmetrical combinations (*i* and *u*), each having on the outside a biconvex lens (*A* and *B*) and inside thereof a biconcave lens (*C* and *E*) of smaller refractive index, and on the inner side of the combination forming the member (*i*) nearer the object a meniscus (*D*).

## RECENT IMPROVEMENTS IN PHOTOGRAPHIC LENSES

MESSRS. GOERZ & VAN HOUGH.

THE patentees point out that photographic objectives have been previously constructed consisting of three lenses, in which spherical and stigmatic distortions are corrected by each two lenses following one another, and cemented together, containing a dividing plane giving a light dispersion and one for light concentration.

Figs. 1 and 2 show the arrangement of such objectives in axial section. In both objectives a lens of medium refraction is enclosed between a lens of smaller and one of greater refracting power. In the form of fig. 1 the enclosed lens has a negative, the enclosing lenses a positive focal distance; in the form of fig. 2 the enclosed lens has a positive and the two others a negative focal distance.

In both cases, by the light-dispersing cemented plane, *z*, means is given for compensation of the spherical deviation, and, by the light-concentrating plane, *s*, means for correcting stigmatic deviation.

The operative opening, which can be given to systems of this kind, and thereby the illuminating power of the objective, is dependent upon the size of the difference between the refractive indices of the kinds of

glass meeting at the cement places, because, the smaller these differences, the deeper curves the cemented planes must have to compensate for the before-mentioned faults; but the curvature of these curves must not surpass a certain admissible amount, otherwise the distinctness of the picture received by the objective would be destroyed. The refracting indices of those kinds of glass which can be used for such objectives lie within the values 1.51 and 1.61, and hence the middle glass has a refractive index between these limits; the differences of the refractive indices can, on the average, therefore not exceed 0.05.

In order to have a greater illuminating power, without augmenting the number of the lenses, and while preserving the distinctness of the

picture and the correction of all faults, they do not use, as in the above-mentioned objectives, a light-dispersing cement plane, but this correction is attained by the lenses at the place, *z*, receiving, not the same, but different, radii of curvature, so that the curve of the negative lens is greater than that of the positive lens, and so that between both now distanced lenses an air space of the form of a positive meniscus is formed. In consequence of this arrangement, it is no longer required that, for correcting spherical deviation, the negative lens should have greater refractive index than the positive one, or, what is the same, that the enclosed lens should be made of a glass of a medium refraction, but one can, in this case, make the middle lens, when it is a biconcave negative one (fig. 3), of very low refracting glass, or, if it is

(fig. 4) a biconcave positive lens, of a glass as strongly refractive as possible. The direct consequence of this is that in both cases, at the light-concentrating cement plane, *s*, two species of glass of very great difference of refractive index meet together, and that consequently this plane compensates for stigmatic deviation, with notably less curvature than was formerly possible.

An advantage of this new arrangement of the lenses, which is not less important than the augmented light power and distinctness of the picture is, that with it, it is also possible to meet the so-called requirement of sine in every single system to the fullest extent, that is to say, it is possible to take also into account the distinctness of the picture obtained by the single system itself of oblique falling pencils of rays, while using the full objective opening, by the possibility of annulling the coma in a certain direction of the chief ray, which was not possible with cemented three-lens systems, in which other faults have been completely compensated.

The numbers inscribed on the drawings give the coefficients of the kind of glass used for the respective lenses. The cemented plane, *s*, concentrates the light; the plane, *z*, disperses the rays.

It is clear, without further explanation, that one can put together two of the described lens systems, and can use them as a compound objective.

The claims are:—

1. A three-lens system for photographic purposes, formed by a cemented meniscus of two lenses, one biconcave lens of lower and one biconvex lens of higher refraction, in conjunction with

(a) Either a meniscus of positive focal distance put in front;  
(b) Or a meniscus of negative focal distance put behind,  
wherein the surfaces, lying one opposite one another, have such curvatures that between the single and the cemented meniscus an air space in the form of a positive meniscus is formed.

2. A compound or double objective formed of two-lens systems as in Claim 1.

## PICTORIAL STEREOSCOPIC CARDS.

HEER OTTO HYMMEN has devised means for utilising stereoscopic photographs in the following manner:—

1. On correspondence cards or the like of all kinds serving the same objects as the well-known picture post cards, but more completely in so far as they allow the object of the representation to appear not as a surface picture, but, by the help of a stereoscope, as corporeal and plastic images.

2. On cards or strips for reproducing instantaneous exposures, following one another in rapid succession, of moving objects with the object of producing spacious living pictures by the combination of the stereoscope and the kinoscope, cinematograph and other like apparatus.

3. On cards or strips for teaching by sight within the domain of natural sciences, architecture, technology, industry, manufactures and the like. It is not desired to cover cards with stereoscopic figures for the study of stereometry, spherical trigonometry, displayed geometry and crystallography, as such as are already known.

4. On cards or strips for reproducing patterns or samples, machines, and manufactures for replacing the original patterns or samples more particularly where the weight of the article or its heavy composite mould or form hardly admits of or entirely prevents the sending or transportation of the original pattern or the making of a drawing.

The cards or strips with stereoscopic representations may consist of cardboard, paper, celluloid, or any other suitable material, and, of course, such cards or strips may be bound or fastened together to form books, albums, rolls, series or the like.

Correspondence cards, letter paper, and the like, which have hitherto only been provided with simple (flat) views or pictures (such as illustrations of the locality from which the correspondence is dispatched) are by this invention provided with two related views of the same subject forming a stereoscopic pair. A postal card, letter, or the like, having such a stereoscopic pair imprinted as a heading or at some other suitable part, thus becomes of greater interest to the person receiving it, as by placing it in an ordinary stereoscope a plastic or relief view may be had which is much superior to the usual flat simple views.

In the application of the invention to the reproduction of instantaneous exposures with a stereoscopic effect, Herr Hymmen arranges two sets of a series of pictures one on each of two endless or continuous strips, the related pictures of each set forming stereoscopic pair, when appearing side by side as shown in fig. 18, in which the views on the band, A, form stereoscopic pairs with those on the band, A'. Stereoscopic sight-holes are provided as shown, and the bands may be put in motion by any of the known mechanisms usual in kinetoscopes or cinematographs. Spacious animated pictures may thus be produced.

The strips of views in stereoscopic pairs may similarly be applied to a zoetrope or round panorama, as shown in figs. 15, 16, and 17, instead of the ordinary single or flat views. In the arrangement shown in fig. 17,

in which the strips are arranged one over the other, it is necessary to provide a suitable arrangement of mirrors to one of the sight-holes so as to make the strip, A, appear to the sight on the same level as the strip, A'. In figs. 15 and 16, the pairs are arranged side by side on a single strip.

In the application of the invention to teaching by sight, and also for reproducing views of patterns, samples, machines, and manufactures, and the like, double pictures forming stereoscopic pairs are provided in place of the usual simple (flat) pictures. These stereoscopic pairs may be mounted or arranged in a variety of ways. For instance, they may be mounted side by side in position for viewing in the stereoscope as shown in fig. 14, or each picture of a pair may be mounted separately as in figs. 1 and 13, and a suitable frame be provided whereby the two related pictures, A A', may be held together when required. This loose arrangement of each picture of a pair allows of the single pictures being utilised as ordinary single or flat views when not actually in use in the stereoscope. By this means the inartistic effect of two similar pictures being exposed to view side by side on a single mount may be avoided when the views are out of the stereoscope. Fig. 11 shows such a frame with separate pictures, A A', forming a stereoscopic pair on the backs of which are other pictures forming another pair. By reversing one picture, say A', when not in use in the stereoscope, one picture only for each pair (i. e., A, A') will be exposed (fig. 12), thus avoiding the inartistic effect of repetition as before stated. Fig. 3 shows the related pictures of a pair connected with a hinge movement for the same purpose.

Where a series of stereoscopic pictures are required, they may be arranged in strips which may be either flat or made to fold. Figs. 4 and 5 each show a folding strip, but with the related pictures of each pair

arranged in series in fig. 4 and in parallel in fig. 9. Two separate folding strips may, however, be used for the pictures of each pair as in fig. 10, the "lefts" being on one strip and the "rights" on the other strip. Fig. 8 shows another arrangement in which two strips are hinged together so as to be adapted to show the pictures separately or in pairs, and fig. 2 a similar arrangement on two separate flats. Fig. 6 shows a folding arrangement in which the related pictures of stereoscopic pairs are separated to avoid the inartistic effect before pointed out, but allowing of any pair being brought together when required for use with the stereoscope.

Where the pictures are bound up in book form the related pictures of a pair may be placed, the "left" on page 2 and the "right" on page 5, as shown in fig. 5, the intermediate leaf, that is pages 3 and 4, being utilised for descriptive matter and acting also as a partition wall for the stereoscope, or the one picture only of each pair may be bound up in the book, and the related pictures to complete the stereoscopic pairs be provided in the form of a supplement to the book as shown in fig. 7.

#### AT THE CAMERA CLUB.

MONDAY last week was a kind of Open Night at the Club, in the sense that there was no fixed lecture or settled programme. Members were invited to exhibit and explain any novelties which might have come under their notice, or which they themselves might have evolved from their inner consciousness. Such evenings are, as a rule, by no means barren of results, and many a useful thing has on these occasions made its first bow to the photographic public. One hopeful sign there was in the circumstance that Mr. Inwards occupied the chair, for this gentleman has the happy knack of seeing the merits of a thing at a glance, and can explain its advantages with clearness and precision. He first called upon Mr. Teale to show a new form of camera which that member of the Club had recently constructed.

The novel feature of this camera is that it requires no focussing glass or screen, this duty being performed by a view-finder coupled with a mirror. The mirror works upon a pivot, and is so adjusted that when the view is correctly focussed half of the image is seen in the view-finder and the other half in the mirror. We hope to have the opportunity of publishing a sketch of the apparatus later on, without which it is impossible to describe it in a more detailed manner.

Dr. Lindsay Johnson was next requested to exhibit an apparatus which he had constructed to test the speed of shutters. He reminded his hearers that he had previously distinguished himself by the invention of many things of no use to anybody, but he trusted that the contrivance which he now showed would not come under the same category. Shutters were most deceitful things, and he found that most of them professed to move about ten times quicker than they actually did. When you see one which is estimated to work at  $\frac{1}{1000}$  second, it is best to disregard it, and meditate upon the story of Ananias and Sapphira his wife.

The apparatus in question takes the form of a small box, in which, by a clockwork movement, a disc pierced by four equidistant holes revolves against a fixed disc pierced with many more holes at stated intervals. By holding the apparatus up to the light, and interposing the shutter to be tested between it and the eye, at the same time regulating the speed of the revolving disc to, say, one turn per second, it is possible, by noting the number of holes visible at the moment of releasing the shutter to calculate its rate very accurately. Dr. Johnson concluded his demonstration by presenting the apparatus to the Club, for the use of the members, a statement which immediately evoked a hearty vote of thanks.

It may be noted that the Camera Club has among its members many who devote themselves to mechanical pursuits, and some of these gentlemen were now called upon to show specimens of their ingenuity. As these exhibits were not photographic in their nature, we cannot consider them here; but we may make an exception in the case of several new patterns of drawing-pens, shown by the Chairman, for a photographer often finds this form of pen necessary in his work. These pens showed much ingenuity in overcoming faults inherent to the ordinary instrument.

Mr. Lyon showed a very ingenious form of instrument for drawing a parabola, which he had previously exhibited at the Royal Society. Mr. Inwards stated that he had made one of somewhat similar design, and that he had subsequently found that he had been anticipated by a Dutchman who lived about three centuries ago, and had published a drawing of the contrivance in a Latin work of that date.

That such an apparatus, old as it was, was wanted in our English workshops might be judged from the circumstance that all our warships, big and little, required parabolic reflectors for their searchlights, and he had ascertained that these were made at Nuremberg at a cost of 100l. a piece, because they could not be manufactured in this country.

Dr. Johnson detailed a curious discovery which he had made in his examination of the eyes of different animals in the Zoological Gardens, and that was that, without exception, the cornea of the eye of mammals exhibited a parabolic curve, and was not spherical. By pressing a plastic substance on the eye, subsequently making a plaster cast from the mould thus formed, and cutting the cast in half, he was able to ascertain this fact. It may be mentioned that Dr. Johnson has on former occasions explained to the Club the various optical devices by which he is able to distract the attention of the fiercest animals whilst examining their eyes

—methods which would possibly never occur to a less able and resourceful operator.

On Thursday, the 20th ult., Chief-Justice Ryner of Lagos gave a picturesque description of this little-known colony of ours on the West Coast of Africa, especially interesting because it is one of our most recent acquisitions, British possession of it dating only from the year 1861. The lecturer has had ten years' experience of the country and its people, and was able to give a very clear account of the place. Moreover, his photographs, taken under great difficulties, were singularly good and evoked much applause. As the lecture was not of photographic interest, we do not give any detailed account of it; but it is interesting to note that the lecturer, like so many other photographers who have worked in tropical regions, complains sadly of his plates frilling. He tried all kinds of remedies, and finally gave the matter up as a thing which could not be cured, and must therefore be endured. "It cannot be helped," he said, "many films bearing what you think will turn out to be fine negatives float entirely off the plate." Alum, before and after fixing, seemed to afford the best check. Some plates frilled more badly than others, but none were free from the fault. His developer was pyro potash.

On the following Monday Mr. T. C. Hepworth gave a lecture and demonstration, his subject being the new apparatus called the Biokam, for taking and exhibiting animated photographs. As this instrument has already been described in our columns, it will not be necessary to enter into any details of its construction; but we may mention that Mr. Hepworth adopted a plan for showing the audience the construction and working of the instrument which might often be adopted by lecturers with advantage to themselves and their hearers. He showed a series of lantern pictures which exhibited every movement and phase of the new instrument. If a button had to be pressed here, or a catch raised there, a picture was shown with a finger doing the work. This was, of course, far better than the usual plan of holding up at the lecture table an article far too small for any one to see perfectly, or handing round the machine for individual examination.

Thanks to these lantern pictures, the Biokam was thoroughly understood by the audience by the time the demonstration of its projecting powers took place. About one dozen films were thrown on the screen by means of an electric lantern, the magnification being no less than 100 diameters. In spite of this strain the details of the pictures came up well, and there was plenty of illumination. It was pointed out that the pictures must be regarded as experimental ones, for it was impossible to attain perfection at the first attempts, and of late the weather had militated against first-class photography.

A very interesting discussion followed with regard to the pioneer efforts to produce action upon a lantern screen—a discussion in which Lord Crawford, Mr. Stroh, Mr. Bros, Mr. Gambier Bolton, and others took part. All agreed that the instrument which had been shown was most ingenious in construction, and was wonderfully compact considering the many purposes it was designed to fulfil. Mr. Humphrey occupied the chair, and conducted the proceedings with his usual tact and kindliness.

#### EXHIBITION OF THE WEST SURREY PHOTOGRAPHIC SOCIETY.

THE West Surrey Photographic Society held its Eleventh Annual Exhibition of members' work on the Wednesday, Thursday, Friday and Saturday, of last week at the Railway Hotel, Battersea-rose, S.W.

The Society has changed its quarters since the last Exhibition, but has been fortunate enough to secure a meeting room which answers admirably as an exhibition gallery. The number of photographs at this year's Exhibition was perhaps a little smaller than usual, but the average quality had not fallen off. We missed the work of the late President (Mr. G. H. James), but his influence was plainly shown in many of the exhibits, and naturally the gum-bichromate process was strongly in evidence, E. Pointon and S. W. Wensum in particular being exponents of this method of printing. The Judges were Colonel J. Gale and Mr. J. Taylerson, and they were empowered to make one award in each of the three classes. The award was withheld in the Portrait and Figure Class, but we could not help thinking that a little figure study by Mr. A. W. Curtis must have entirely escaped their notice. It was certainly one of the best things in the Exhibition. In the landscape class, the awards were made to Messrs. H. P. Hoad and W. H. Wilshe, and in the Class for Seascapes to Mr. T. E. Meadowcroft. In addition to the exhibitors whose names have already been mentioned considerable work was shown by the President (Mr. J. T. Price) and by Messrs. J. Bulbeck, G. Bottle, and C. Shead.

One of the most interesting features of the Exhibition was a collection of studies of fruit and vegetables, the result of one of the Society's competitions, the principal examples being by Messrs. E. W. Burch, A. W. Curtis, E. Pointon, and W. H. Wilshe. Of the collection we can speak in unqualified praise. Such subjects are not very frequently treated by photography, and in hitting upon such a novelty in the way of subjects for competition an opportunity has been given to prove that many of the prosaic articles of every day life lend themselves to pictorial effect when suitably dealt with.

## Our Editorial Table.

### "CALCIUM" PAPER.

L. Trapp & Co., 29, Budge-row, E.C.

MESSRS. TRAPP are placing on the market a new collodio-chloride paper, "Calcium," which is issued with both glossy and matt surfaces. Rapidity of printing, freedom from curling, excellence of tone, and permanence of results are amongst the characteristics claimed for the new paper, with which we have been very pleased. Full instructions for the use of a variety of toning baths are issued with the paper, of which many Continental photographers speak highly. As we have many times before pointed out, owing to the chemical inertness of the vehicle a collodion paper has particular claims to the notice of the photographer. In physical respects we find this one to behave admirably.

### THE CADETT ORTHOCHROMATIC LIGHT-FILTER.

MESSRS. CADETT & NEALL are issuing the following notes on the use of their orthochromatic light-filter: These light-filters are adjusted for the rapid series of the spectrum plates, and will render all colour luminosities correctly, with a small margin of error. Each light-filter is carefully tested by Mr. Cadett with the latest improved form of Captain Abney's colour sensimeter. The filters are of no use for any other orthochromatic plate than the Rapid Spectrum series. The best and most easily arranged position for the filter is immediately behind the lens in the camera, care being taken to exclude all reflected light between the filter and the lens. The filter can, however, be placed in any suitable position. Care should be taken to avoid leaving the filter in direct sunshine or long-continued daylight; when not in use, it should be kept in its case. The surfaces being optically worked, the filter should be treated as a lens, and every care taken to avoid scratches.

The colour luminosities are rendered as they appear to the eye, in the quality of the light by which the subject is photographed. By special order, the filters can be paired for stereoscopic negatives.

The following developers are recommended for use with the spectrum plates:—

#### No. 1.

##### PYRO-SODA DEVELOPER.

##### Stock Solution.

Pyrogallie acid.....	1 ounce.
Potassium metabisulphite ...	30 grains.
Distilled or soft water to make altogether .....	9 ounces fl. and 55 minims.

Every 10 minims of stock pyro solution contains 1 grain of pyrogallie acid.

A.—Stock solution .....	8 ounces fl.
Distilled or soft water to make altogether ...	20 "

B.—Sodium carbonate cryst. (washing soda, select translucent pieces) .....	350 grains.
Sodium sulphite cryst. ....	700 "
Distilled water to make altogether .....	20 ounces fl.

Equal parts of A and B to make developer.

#### No. 2.

##### METOL DEVELOPER.

##### One Solution Only.

Distilled or soft water .....	80 ounces fl.
Metol .....	1 ounce av.
Sodium sulphite (pure recryst.) .....	5 ounces.
Sodium carbonate (cryst.) (washing soda, select translucent pieces) .....	6½ ounces.
Or instead anhydrous sodium carbonate .....	2½ "

##### HYDROQUINONE DEVELOPER.

A.—Hydroquinone .....	120 grains.
Sodium sulphite (recryst.) .....	250 "
Potassium metabisulphite .....	8 "
Distilled or soft water to make altogether ...	20 ounces fl.

B.—Sodium carbonate (cryst.) (washing soda, select translucent pieces .....	2½ ounces av.
or	
Sodium carbonate anhydrous.....	360 grains.
Distilled or soft water to make altogether ...	20 ounces fl.

Equal quantities of A and B to make developer.

##### FIXING BATH.

Hypo .....	1 pound.
Water .....	1 quart.

## FERROUS OXALATE DEVELOPER.

A.—Neutral oxalate of potash .....	1 part.
Distilled water .....	4 parts.
B.—Protosulphate of iron .....	1 part.
Citric acid .....	1½ "
Distilled water .....	3 parts.
C.—Potassium bromide .....	1 part.
Distilled water .....	3 parts.

For use, take A, 100 parts; B, 25 parts; C, 10 parts.

## CATALOGUES RECEIVED.

FROM MESSRS. HARRINGTON BROTHERS, 4, Oliver's-yard, City-road, E.C., we have received their April price-list of chemicals used in photography.

MR. JAMES D. GRIFFIN, of Floodgate-street, Birmingham, sends us his catalogue of photographic and microscopic glass. This is a useful list of twenty pages devoted to lantern and camera glass; positive glass; opalines, backs and boxes; vignetting glasses; plate-glass cutting shapes; matt-surface opals; ruby, orange, and other coloured glass; dark-room lamps; microscopical thin glass (in squares and circles); glass slides in sheet, crown, and patent plate, also with cavities in centre, &c.

We have also received "Results of Meteorological and Magnetical Observations in 1898 at Stonyhurst College Observatory," by the Rev. W. Sidgreaves, S.J., F.R.A.S.; "On the Reflection of Cathode Rays," by Mr. A. A. Campbell Swinton (a paper read at the Royal Society on February 9); *La Photographie Anisée*, by Boleslas Matuszewski, published at 8, Rue Campagne-Première, Paris; the *American X-Ray Journal* for March; "The Colour Principle of Trichromatic Printing," a lecture by C. G. Zander, read at a meeting of the Institute of Printers and Kindred Trades of the British Empire on April 19; *Principles et Pratique d'Art en Photographie*, by Frederic Dillaye (Paris: Gauthier-Villars).

## News and Notes.

THE Oxford Camera Club has commenced the issue of printed proceedings to be published three times a year.

PHOTOGRAPHIC CLUB.—May 3. Demonstration of the Weiss Flashlight Apparatus, by Mr. Reinhold Thiele.

THE Earl of Crawford will preside at the Annual Dinner of the Camera Club, to be held at the Club House, Charing Cross-road, W.C., on Thursday evening next, May 4.

PARIS EXHIBITION, 1900, AND PATENTS.—Interested parties may see at the London Chamber of Commerce the full text of the law regarding the protection to be granted to patents, &c., which may be exposed (in a technical sense), at the Paris Exhibition of 1900.

THE management of the Canterbury Music Hall send us a half-tone picture of the members of the company now appearing at that popular place of entertainment. There are forty-five portraits, and a key block is supplied. The original photograph was taken by Mr. E. Sharp.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—The next meeting of this Society will be held on Monday, May 1, when Mr. F. O. Bynoe will deliver his popular lecture, "Camera and the Wheel." Tickets of admission can be had of the Hon. Secretary, Mr. Alfred T. Ward, Cripple-gate Institute, Golden-lane, E.C.

MESSRS. MAWSON & SWAN, of Soho-square, London, and Moseley-street, Newcastle-on-Tyne, announce a competition open to all users of their dry plates and films. One hundred and twenty pounds are offered in sixty prizes, and there is no entrance fee. Prospectuses giving full particulars may be obtained of the firm at either of the addresses named.

THE Holland Fine Art Gallery, which is being established in London at 235A, Regent street, W., with the object of introducing the art of the Netherlands more fully to the British public, will open shortly with an Exhibition of paintings by famous masters, including examples by J. Bosboom, Israëls, Manve, Mesdag, M. Maris, Nuhuys, W. Maris, J. Maris, Poggenbeek, and others.

A NEW use has been found for the motor cab. A woman having broken her leg in the street, a motor cab and a doctor were telephoned for, and arrived simultaneously. The doctor brought an X-ray apparatus, and the cab brought the battery. The two being combined, an excellent skiagram of the lesion was obtained, and suitable first aid rendered. The battery was then disconnected from the Röntgen tube, and by its means the cab took the woman to the hospital.

THE members of the Edinburgh Photographic Society had their first outing for the season on Monday, 17th inst., under the leadership of Mr. A. Eddington, F.J.I. The places visited being Selkirk, Newark Castle, Bowhill, and Oakwood Tower. The weather conditions were all that the most fastidious photographer could desire. In the evening the members dined together at the Selkirk Hotel. On the motion of the Librarian (Mr. J. Anderson) a hearty vote of thanks was accorded the lender for his excellent services, the Librarian mentioning at the same time that this had been one of the most successful outings ever held by the Society.

AT Exeter on Tuesday was opened a very attractive exhibition of photography, under the auspices of the Exeter Camera Club. The Exhibition remained open until Friday. The arrangements were admirably carried out by the Hon. Secretary, Mr. C. R. M. Clapp, assisted by the Committee of the Club. It was entirely a loan collection—no medals or other prizes being offered—and comprised 163 frames. Of these, twenty-one were lent by the Glasgow and West of Scotland Association, ten by the South London Society and fifty by the Birmingham Society, whilst the Exeter Camera Club showed seventy-five. The Exhibition, as it stood, was somewhat smaller than its predecessor last year, but was generally considered to be an advance artistically, the contributions of local members showing marked improvement.

EXHIBITION AT ROTHERHAM.—The Tenth Annual Exhibition of the Rotherham Photographic Society was held in the Drill Hall, Rotherham, on Thursday, Friday, and Saturday, April 20, 21, and 22. The opening ceremony was performed by Major C. J. Stoddart, J.P., in the presence of a fairly large company. Dr. Baldwin (the President) occupied the chair. The Members' Work and Loan Collection were most effectively displayed, bays having been arranged and special lighting facilities provided. Compared with previous years, the standard, from the Society's point of view, was well maintained. Twenty-one members sent exhibits, and, although largely topographical, with a leaning towards architecture, there were, nevertheless, some very effective subjects. Careful technique was noticeable, but some of the landscapes suffered through lack of suitable clouds. It should be mentioned that many of the examples were, doubtless, intended for the Photographic Survey collection. The contributors in the Members' Section were Miss Crossley, Messrs. G. B. Brook, J. Caseldine, J. Clark, J. C. Cox, W. J. Dawson, Wm. Firth, W. E. Garsed, B. Godfrey, A. R. Habershon, H. C. Hemmingway (Hon. Secretary), R. H. Law, J. Leadbeater (Vice-President), A. S. L. th (Hon. Treasurer), W. Mason, G. T. M. Rackstraw, J. Turner (Vice-President), P. G. Turner, J. W. Stamp, C. H. Sutton, and F. A. Winstanley. Mr. Leadbeater's series of reproductions of old engravings were exceedingly interesting. The Loan Collection included the Royal Photographic Society's series, and examples by the Autotype Company, London; Mr. Worsley Benison, Chesham; Mr. T. A. Scott, Derby; and Mr. T. G. Hibbert, Sheffield. The trade firms giving their aid were Messrs. R. & J. Beck, Limited, Cadett & Neall, Elliott & Sons, J. J. Griffin, Limited, Kodak Limited, Marion & Co., Paget Prize Plate Company, and Wellington & Ward. Each evening there were lantern shows, the members' slides being supplemented by the series of the Royal Photographic Society. The Eastwood Orchestral Band played choice selections, and there was enjoyable vocal music contributed by friends. On Saturday evening the Rotherham Borough Prize Band gave their services. Generous support was forthcoming from the public, and the Sheffield societies sent a fair representation. Several sales of members' work took place, and the money thus received will be handed over to the Treasurer of the Rotherham Hospital.

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
1.....	Bradford Photo. Society ....	{ With Cycle and Camera in Lakeland. G. Thistlethwaite.
1.....	Camera Club .....	Opening of Members' Exhibition.
1.....	Cripple-gate Photo. Society .....	Camera and the Wheel. F. O. Bynoe.
1.....	Putney .....	Annual General Meeting.
1.....	South London .....	Prize Slides, 1898.
2.....	Ashton-under-Lyne.....	Demonstration on Developing.
2.....	Camera Club .....	Lantern-slide Evening: Lullus' Night.
2.....	Hackney .....	{ Some Simple Optical Experiments. Rev. F. C. Lambert.
2.....	Isle of Thanet .....	{ Demonstration: Plant and Flower Structure—How Best to Prepare as Lantern Slides. G. Dowker, V.P.

5.....	Croydon Microscopical .....	Conversational Meeting.
6.....	Croydon Camera Club .....	{ Excursion: Beddington. Leader, W. H. Rogers.
6.....	Hackney .....	{ Excursion: Chislehurst. Leader, S. C. Stean.

## ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 25.—Technical Meeting.—The Right Hon. the Earl of Crawford, K.T. (President), in the chair.

## SPECTROSCOPIC PHOTOGRAPHY.

THE HON. SECRETARY (Colonel Waterhouse) showed a print, sent by the Kodak Company, from a negative taken by Sir Norman Lockyer, of the arc spectrum of iron, with a comparison spectrum of the sun from wave-length 3600 to wave-length 5200. He read a memorandum, from which it appeared that Sir Norman had lately been experimenting with flexible film, with the idea of adapting it to spectroscopic photography. The large concave Rowland grating which he used had 20,000 lines to the inch, and was of 21½ feet radius, giving a spectrum of 30 inches in length; the focal plane of this grating being of necessity considerably curved, it was impossible to get a sharp photograph of the whole spectrum on a glass plate, but he had got over this difficulty by the use of the Company's flexible film bent to the

curvature of the field. The print shown was said to be the longest solar spectrum ever photographed at a single operation, being 30 inches long. Sir Norman Lockyer hoped, by using films at the next solar eclipse, to be able to obtain a greatly increased number of photographs, owing to the rapidity with which the film could be shifted in the short space of time available for photographic operations. It was stated that an apparatus for carrying films was in course of completion, which could be adapted to the spectroscopic cameras at present in use in the laboratory and observatory.

The PRESIDENT said he had never worked with a Rowland grating, but he had used a plane grating of about 23,000 lines to the inch and obtained a spectrum of about the same length as that shown; the focal plane, however, being by no means flat, he was compelled to use his glass plates in short sections so as to take chords of the arc. He believed that Dr. Copeland, the former director of his observatory, and now Astronomer Royal for Scotland, had for some time past utilised films for work of this description, and that therefore the use of flexible film in this direction was not absolutely new, but the photograph now exhibited was a remarkably fine one.

#### LIGHTNING.

Mr. J. Sterry submitted a photograph, presented to the Society by Mr. Wing, of a compound lightning flash. Mr. Glew, in a recent paper, had said that he had never seen a lightning flash consisting of more than three components, but this photograph by Mr. Wing had been examined by Mr. Glew, who found that it contained three distinct flashes—one single flash, one with two components, and one with either six or seven components.

#### GLASS DIAPHRAGMS.

Mr. T. Bolas, F.I.C., F.C.S., gave an exceedingly able and interesting demonstration of "The Making of Glass Diaphragms, Thin to Newton's 'Very Black' Stage," in the course of which he manipulated the blow-pipe and glass tubes with such dexterity as to draw from the President the remark that he deserved to be known as a "fairy-fingered Bolas." He pointed out that the thin glass of the bursting bulb must necessarily be much wanting in flatness, and that in its thinner forms, as he showed by experiment, it was a mere irregular fringe; moreover, it was seldom thinner than to give Newton's third order of colours (from about twelve to twenty millionths of an inch for flint glass). He then demonstrated the fact that approximately flat diaphragms of any thinness up to that giving Newton's blacks (from about one millionth of an inch to one three-millionth for flint glass), could be prepared by preparing a glass bulb, with a thin diaphragm across it, and two necks, one on each side of the diaphragm. This bulb being expanded by equal air pressure on both sides, the diaphragm could be slowly stretched to any required extent while kept hot by the surrounding mass of glass. The diaphragms thus made were approximately flat, and it was suggested that, being mounted in air-tight and convenient setting, they might lend themselves to many applications in demonstrative physics, especially in relation to phase reversal as affecting the theory of the Lippmann heliochromy, and also as to the greater limit in estimates of molecular magnitude. The thicker diaphragms, silvered, would form delicate manometric mirrors for photographic registration, while the thinner might form molecular filters of an altogether new class. The skill with which Mr. Bolas carried out his delicate demonstration was much appreciated by the meeting, and his ultimate success in attaining the "very black" stage was warmly applauded.

An informal discussion followed.

#### THE HALOID SILVER COMPOUNDS.

COLONEL WATERHOUSE exhibited some specimens of silver chloride, bromide, and iodide, produced by dry double decomposition through pounding in a mortar. When recently making some experiments on the lines of Carey Lea's observations on the effect of mechanical pressure or friction on the silver haloids, the idea struck him that it might be possible to form these haloid compounds mechanically by pounding silver nitrate and the alkaline halogens in a mortar, and, finding that Becquerel had stated that the iodide of lead could be formed in this way, he had tried the experiment with the three haloid salts of silver referred to, using mixtures of silver nitrate with common salt and potassium iodide and bromide. He also showed some silver chloride which had been darkened by continued pounding in a glass mortar, and stated that, although this specimen was not very dark, he had succeeded in getting a strong reddish chocolate colour on the sides of the mortar and the end of the pestle. Colonel Waterhouse read a note in which he gave details of his experiments, and referred to the observations of Carey Lea and Becquerel upon the subject.

#### COMING EVENTS.

May 9, Ordinary Meeting. "Photography of Colours," by Mr. Sanger Shepherd. May 16, Photo-mechanical Meeting, subject to be announced. May 23, Technical Meeting, "Korea," Mrs. Isabella Bishop.

#### PHOTOGRAPHIC CLUB.

APRIL 19.—Mr. H. Snowden Ward in the chair.

Mr. F. H. EVANS gave a lantern lecture on "Gloucester Cathedral," illustrated with a collection of slides, the excellent character of which almost exhausted the powers to praise of a large and appreciative audience. Mr. Evans prefaced his exhibition with some well-chosen words on the several types of architecture to be found in this and other English cathedrals, and then proceeded with such a systematic representation of the beautiful features comprised within the walls of Gloucester Cathedral that, spacious as it is in fact, in fancy one conjured up an edifice of far greater proportions. Particular interest attached to the display on account of the impending visit of the Photographic Convention to Gloucester early in July, when Mr. W. Crooke, of Edinburgh, presides, and the Mayor will open the proceedings for which the Guildhall has been courteously granted.

Mr. BRIDGE, the Hon. Secretary of the P.C.U.K., in moving a vote of thanks to Mr. Evans, referred to the slides as a specimen of what was to be found in and around the Convention's next meeting place, and, though he rather thought that

Mr. Evans had left little unphotographed, yet, from what he knew of the untiring energy of Conventioneers—they suffered very greatly from this species of disease—he had little doubt that they would not return without something new as the result of their endeavours.

**Croydon Microscopical and Natural History Club (Photographic Section).**—On Friday evening last Mr. GEORGE SCAMMELL came down to Croydon in order to lay before the members of this Club the work proposed to be carried out by the National Photographic Record Association. It was suggested that a number of centres should be formed, and societies working around such centres should take up the work, and thus avoid as far as possible the duplication of result. A map was shown, indicating how this was to be done. Everything ought to be done by scale, and Mr. Scammell showed a printed scale marked in yards and metres with their subdivisions, which could be included in the photograph. A mount, too, was shown, to take four quarter-plate or two half-plate prints, cut out and sunk to protect the prints, which could be obtained for half-a-crown a dozen. The prints themselves must be absolutely permanent, obviously, and therefore only carbon or platinum prints would be accepted, bromide or P.O.P. being excluded. It is needless to say that Mr. Scammell handled his subject in a most pleasing and lucid manner, the pity being that the weather was as bad as bad could be, and prevented the attendance which would otherwise have been present and which the subject deserved. Some seventy slides followed, showing the class of work which has so far been accomplished. At the conclusion, the CHAIRMAN (Mr. W. Merton Holmes) proposed a cordial vote of thanks, which was carried enthusiastically.

**Lewisham Camera Club.**—April 18, Mr. M. Stodart opened a discussion on

#### LENSES.

describing the defects inherent in the older types, but which were entirely absent in modern lenses, owing to the invention of Jena glass, the method of manufacturing which he described. As a result of the discussion it seemed to be the opinion amongst the majority of the members that, except for rapid work, no distinct advantage was derived from the use of the newer lenses, as they required stopping down in order to obtain depth of focus, and the production of a sharp image over a considerable angle was not always essential in landscape work.

**North Middlesex Photographic Society.**—April 17, Instruction Meeting, Mr. E. R. Mattocks in the chair.—Mr. Child Bayley showed a couple of lantern slides, which he had exposed twenty or thirty times the correct time, and fixed and then developed with Wellington's sulphocyanide intensifier. They were as clear and dense as one could wish, and of good colour. Mr. H. W. BENNETT, F.R.P.S., gave a lecture on

#### DEVELOPERS AND THEIR MODIFICATION.

In his preliminary remarks he said that it was false that amidol and other newer developers allowed curtailment of exposure, and instanced two examples in which the exposure had been very short; one was developed with amidol and the other with pyro and ammonia. The result was in favour, if any, of the pyro-developed one. He gave a formula for a standard pyro developer, that is, for correct exposures: 1. Pyro, 1 ounce; nitric acid, 10 minims; water, to 9½ ounces. 2. Pyro, 1 ounce; metabisulphite of potash, 1 ounce; water, to 9½ ounces. 3. Pyro, 1 ounce; sulphite of soda, 4 ounces; citric acid, ¼ ounce; water, to 9½ ounces, made up with distilled water and filtered. The one he generally used was No. 2. To make up for use take pyro, 30 minims of ten per cent. solution as above; ammonium bromide, 15 minims; ammonia, 30 minims (also ten per cent. solutions); make up to 2 ounces with water. If No. 2 pyro is used, take 40 minims ammonia, as the metabisulphite is strongly acid. The temperature of the developer should be about 65° F. If it is much colder, development is prolonged, and a vigorous negative is impossible. The time of development for most plates was from four to seven minutes. He showed three negatives developed for three, six, and twelve minutes with this developer, the same exposure to each. The one developed for six minutes was of the best printing density. It was inexpedient to curtail the time of development if a softer result was desired, as the shadow detail suffered. The developer may be diluted to 8 ounces instead of 2, as in the standard. He showed two examples, one with the standard developer and the other the diluted; in the latter the gradations were in a smaller compass. The time of development was prolonged to fifteen minutes instead of six. Fresh developer should be used for each plate, whatever its composition. He gave two formulae for modifying development: 1. Pyro, 30 minims; ammonium bromide, 5 minims; ammonia, 50 minims. 2. Pyro, 30 minims; ammonium bromide, 40 minims; ammonia, 30 minims, each in 2 ounces of water. He showed examples, normally exposed, treated with these modifications; the time of development with No. 1 was two and a half minutes, with No. 2 twenty minutes. In using an excess of ammonia, as in No. 1, the surface of the plate often showed iridescent markings; these could be quite got rid of by immersing for a few moments in a weak solution of Howard Farmer's reducer. The lecturer then treated of amidol, and gave three formulae: 1. Amidol, 2 grains; sodium sulphite, 10 grains; potassium bromide, 1 grain; water, 2 ounces. 2. Amidol, 2 grains; sodium sulphite, 20 grains; potassium bromide, 1 grain; water, 2 ounces. 3. Amidol, 2 grains; sodium sulphite, 40 grains; potassium bromide, 3 grains; water, 2 ounces. He showed examples of normal exposures developed in these solutions. No. 3 most nearly approached standard pyro developer in the result. They were all developed in six or seven minutes. A plate given two-fifths normal exposure was developed in a solution of pyro, ¾ grains; ammonium bromide, ¾ grain; ammonia, 1½ minims; to water, 2 ounces; and developed for twenty-five minutes. Also one three times normal exposure in a solution of pyro, 3 grains; bromide, 4 grains; ammonia, 3 grains; to water, 2 ounces. The results were shown, and were good, printable negatives, but not up to normal exposure of standard developer. The lecturer said that a practical application of the foregoing was to treat subjects having harsh contrasts with a developer suited to under-exposure, and subjects lacking in con-

trast with one suited to over-exposure. Mr. MacINTOSH, in moving a vote of thanks to Mr. Bennett for his very lucid and practical lecture, queried the advisability of filtering the pyro solution in view of its easily oxidisable nature.

**Preston Scientific Society (Photographic Section),** April 19, Annual General Meeting.—Mr. J. H. Yonge was re-elected Chairman, and M. A. W. Cooper Hon. Secretary. Messrs. G. D. Marsden, G. C. Isles, W. Phillips, Hy. P. Burton, W. Crossdale, and Dr. Sellars were elected as Committee.

**Glasgow Photographic Association.**—At the Fifth General Meeting of the session, held within the Philosophical Society's rooms, Glasgow, Mr. J. Craig Annan (Vice-President) in the chair, Messrs. A. Herbert Brown, George S. Nicol, Charles Raeburn, and John H. Tenby were elected members. The meeting approved of the resolution of the Council to join the other local societies in approaching the executive of the 1901 Exhibition, with a view to obtaining for visitors the privilege of using hand cameras in the grounds of the Exhibition. In the course of the CHAIRMAN'S "Notes on the Journals," amongst others, the subjects of "Sacred Art and the Camera," "The Use of Artificial Light combined with Daylight," "Flower Photography," and "Zone-plate Telescopes and Cameras" were noticed and discussed. Mr. Thomas Manly's new process of "Ozotype with Carbon Tissues" was explained, and the Chairman exhibited results of his experiments in the process. Mr. FRED. MACKENZIE described and demonstrated a new method of exposing plates in the camera, by which, with one specially designed dark slide of the usual dimensions, and paper or other envelopes, plates can be exposed and changed in daylight. Mr. WILLIE ANDERSON gave a demonstration of a new method of vignetting, and exhibited and explained his apparatus. Several very successful prints were made, developed, and exhibited. Mr. A. LINDSAY MILLER favourably criticised the new processes, and moved a vote of thanks to Messrs. Annan, Mackenzie, and Anderson.

### FORTHCOMING EXHIBITION.

1899.

April 28-May 13 ..... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

## Patent News.

THE following applications for Patents were made between April 10 and April 15, 1899:—

**ADJUSTABLE FOCUSSEING SCREEN AND DARK SLIDE.**—No. 7535. "Focussing Screen and Dark Slide, with Carriages for taking up the varying dimensions of Photographic Plates and Fastening Shutters." W. HARRISON.

**DEVELOPING TRAYS.**—No. 7611. "Improvements in Photographic Developing Trays." A. B. SHEPPARD and J. P. LEECH.

**STEREOSCOPE.**—No. 7655. "Improvements in Automatic Apparatus for Successively Presenting to View Photographic Pictures or Slide in Stereoscopes, Optical Lanterns, and the like." L. J. E. COLARDEAU and J. RICHARD.

**PLATE CARRIERS.**—No. 7751. "Improvements in and relating to Means for Carrying and Exposing in the Camera Photographic Dry Plates or Films." F. MACKENZIE and G. WISHART.

**CINEMATOGRAPH CAMERAS.**—No. 7881. "Improvements in or relating to Cinematograph Cameras." H. G. SAGROVE and J. HALL-WRIGHT.

**SHUTTERS.**—No. 7970. "Improvements in or relating to Photographic Shutters." Complete specification. W. O. STANLEY.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### ANOTHER SECRET PROCESS.

To the EDITORS.

GENTLEMEN.—A man has recently called on me, and other photographers in the district, offering for sale a secret (?) process for the production of bas-relief in portraiture, &c., and showing specimens said to be produced by his process, which appeared exactly similar to those produced by the Tarber method. The man offered to impart a knowledge of his process for two guineas, and said he could explain all that was necessary in ten minutes. He subsequently reduced his fee, as a special favour, to one guinea; and, in the case of another photographer near here, to half a guinea. He claimed to have instructed Messrs. Gunn & Stuart (Richmond), besides Hills & Saunders, Mayall, and a goodly selection of well-known firms, and said that the work they showed in bas-relief was produced by his method. Some of his statements were contradictory, and his claim to know all the good photographers in Brighton (which statement I was able to test) proved incorrect. We did

not transact any business with him, and I thought it desirable to write you on the matter to strengthen any information you may already have. You may make any use of this letter, and retain the circular at your discretion.—I am, yours, &c.,

East Molesey, April 25, 1899.

JOHN G. WILLIAMS.

P.S.—The man wrote his town address on back of circular in pencil, but could not supply us with his card, or other printed matter.

[In our ALMANAC for 1898 will be found several processes of bas-relief photography. It is very old, and was known and exploited many years ago.—EDS.]

### THE TANQUERAY PORTRAIT SCHEME.

To the EDITORS.

GENTLEMEN.—There are many unpleasant things that business men come across that it is not always wise to give vent to through the public press, and I am not sure if so much attention given to the "Tanqueray free portraits" does not give the two Americans running that show a good advertisement. Still, on the whole, I think with you, gentlemen, that more light should be thrown upon this subject, hence this letter. I have had recently two of these so-called portraits brought to me to re-work, and hear of a third coming, and quite a dozen customers have referred to the matter during the past six weeks; it is therefore evident that this neighbourhood has been widely circularised.

During several trips to Paris in the past few years I have had a good opportunity of watching Tanqueray's progress. I have seen both his old and small establishment in the Rue des Italiens, and also his present large premises in the Rue de St. Pétersbourg, and there is every evidence that he has made a lot of money out of his scheme. I have before me one of his portraits, and on careful examination I should judge it to be made by the American solar process, there is no trace of gelatine on surface of paper, it looks like an eighty-five gramme Steinbach paper salted, and sensitised with nitrate of silver.

These prints in America are sold to the trade (and they are largely used over there) for five cents each (2½d.), the actual cost to Tanqueray would be about 1½d. The thin mount would cost ¾d. and the air-brush artist would not get more than 9d. or 10d. for his work in an American portrait house. The only postage stamp a portrait recently brought to me was one of fifty centimes, so that the eight francs or eight shillings (most usual) paid for "mailing" leaves Tanqueray a profit of over four hundred per cent. The formula by which this paper is sensitised was offered me by an American for three hundred pounds, another one over here, some four years ago asked five hundred pounds for it, it did not cost me anything.

Enclosed I send you a circular and testimonials from Tanqueray in the Rue de St. Pétersbourg, Paris, also one from his brother-in-law, Schneider, around the corner, in the Rue de Constantinople.

Sometimes this individual has acted as Directeur in place of Tanqueray at the other address, but you will notice that both Schneider and Tanqueray, carrying on distinct businesses in different streets, use the same testimonials, as if addressed to each house individually. It would be interesting also if the public were acquainted with Tanqueray's doings in America and Canada, but I have written for only about what is within my own knowledge.—I am, yours, &c.,

FRANK A. VENNING.

Crayon Limited, 49, Brecknock-road, London, N., April 19, 1899.

### PHOTOGRAPHY AT FUNERALS.

To the EDITORS.

GENTLEMEN.—To my mind, I think there is nothing so utterly obnoxious, as for any one "shopping" on such an occasion; surely the poignant sorrow of the true mourners might be respected, if not the feelings of the general public! But talk about consideration for others, I was completely non-plussed, when some thirty years ago, while taking a photograph of a country church, the clergyman suggested my taking a "photograph of a funeral that was just about to take place—with himself officiating in his white surplice"—and, mind you, not a junior clergyman by any means; suffice it to say, young enthusiast as I was, I nevertheless declined! I hope my brother photographers will exercise a little of the same consideration, and never again be charged with so despicable an act as to attempt to make capital out of such painful circumstances, but—

"DO AS YOU WOULD BE DONE BY."

### A SOCIETY FOR PHOTOGRAPHIC PRINTERS.

To the EDITORS.

GENTLEMEN.—I was much interested in the letter of Mr. F. G. Willatt on the above topic, and fully agree with his desire to more accurately classify the various photographic assistants. I would point out, however, that our trade is a mere infant when compared with carpentry, plumbing, and bricklaying, and, consequently, the distinctions between its various members have not yet reached so definite and fixed a boundary as those between the members of the building trade. Such a clear line of duties as now falls to the carpenter and plumber has only been attained by

years of experience, aided largely by trade-union action. The result is an effect of trade unionism, and a similar condition will prevail in photography so soon as assistants become trade unionists. The difference is merely that between the organized and unorganized.

The want of knowledge concerning trade unionism displayed by the average assistant is well put by Mr. Willatt. "I must be free to take what wage I please," says the assistant, assuming wrongly that trade unionism destroys such a liberty. The trade unionist is much less heroic; he considers wages from a businesslike point of view. In plain language, he tells the "free and independent" that, if 25s. is the general rate of wages for operators, artists, retouchers, printers, the only liberty he enjoys is to accept 20s. or 15s., he not being in a position to do otherwise, since the employer has money and the "free and independent" is penniless. This being so, a trade union undertakes to supply cash, every member paying money down to receive money value in return—a purely commercial transaction for services rendered, the result being that a trade unionist is not compelled to accept 20s. or 15s., but can demand 25s., the full market value of his labour. There are trade unionists to-day who, by the payment of sixpence, or even less weekly, keep up their wages 2s., 3s., 5s., or even 10s. or 11. a week, and with increasing organization the rate of wages will continually rise.

With Mr. Willatt's suggestion that photographic printers should form a union I do not agree. The spirit of the times is entirely against such a course of action. "Fewer unions and more union" is now the motto of the labour world, and every trade-union leader is striving to federate or amalgamate the smaller unions. The last engineers' strike has entirely changed the trade-union outlook, and in the future trade unionism must deal with men by the 100,000 if it is to cope with federated capitalists. The proper policy, in my opinion, is for photographic assistants to join the National Amalgamated Union, particulars of which were given in the JOURNAL of last week.—I am, yours, &c.

JOHN A. RANDALL.

April 21, 1899.

## PINHOLE PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—There has been quite a fuss made of late about photographs being taken by means of a box with a little pinhole. I should like to state that this is no new invention, as I have had such a box in my possession for years, and have only to-day exposed a quarter-plate with splendid results, the negative being perfectly sharp and fully exposed.—I am, yours, &c.,

G. FROST.

West-end Studio, Alton, Hants, April 21, 1899.

[Quite so: pinhole photography is not a "new invention." Indeed the principle of passing an image through a minute aperture may at least be traced back to Sir Isaac Newton.—EDS.]

## IN REPLY TO "FREE LANCE."

To the EDITORS.

GENTLEMEN,—Will "Free Lance" show that a point moving half an inch in  $\frac{1}{100}$  second, must necessarily be represented by a line? Will he also show that every part of a horse in gallop moves at uniform velocity?—I am, yours, &c.,

P. EVERITT.

London, April 22, 1899.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

O. BURTON and J. W. BURTON, Haymarket, Leicester.—Three photographs of Tom Frost.

T. M. BARBOUR, 1, Briarley-street, Bury, Lancs.—Photograph of group of the Bury Football Team with the Lancashire cup.

A. B. LEZARD, Sunningdale, Boxley, Kent.—Photograph of ss. "Stella," with Elizabeth Castle, Jersey, in background.

WILLIAMS & Co., The Studio, Castle-street, Maesteg, Glam.—Photograph of Dr. W. H. Thomas, J.P., M.D., M.R.C.S., L.R.C.P., Maesteg, Glamorganshire.

RECEIVED.—METOL; J. H. C.; F. BROWN; C. GORHAM; R. PRYOR; H. J. HILLHOUSE; and others. In our next.

R. A. FREEMAN.—The paper is not now obtainable commercially.

A. WINTER.—We should not expect to find any loss of definition through the cause assigned.

S.—If your order comes from H.M. Office of Works, we believe it covers Hampton Court Park.

J. B. (Plymouth).—The negatives are your property, and you cannot be compelled to part with them.

W. T. W. S. (Uppingham).—We are very much obliged to you for your letter and enclosure. It is a very painful case; but we prefer to withhold from publication.

CALIFORNIAN.—We do not give recommendations of the nature of that asked for. Better look through the advertisements in our ALMANAC and study the details of the various matter therein given.

RESTORING DAGUERRETYPES.—Messrs. G. and J. Hall, of 9, Westgate, Wakefield write: "If 'C. B.' will send Daguerreotype to us with 2s. 6d., we will either restore it or, if too far gone, return the money less postage."

COPYRIGHT.—1. Yes; the respective assignments would embrace the total length of the term of copyright. 2. In both originals and reproductions. 3. Yes. 4. No; but they may have copyright in photographs of the pictures. 5. Not to America.

THE TELESCOPIC.—G. NAG says: "I have read with great interest your articles about Szczepanik's Telescoposcope in the THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1899. As I am desirous of possessing one of these marvellous instruments, I shall trouble you to let me know where a telescoposcope can be had, and at what price?"—In reply: The instrument referred to is not on the market, and we doubt if it is likely to be yet a while.

CRYSTOLEUM.—B. & S. say: "Can you kindly inform us of any method whereby ordinary gelatine-surfaced paper can be rendered transparent for crystoleum work?"—The only means we can suggest are those used for albumen prints, such as wax, castor oil, paraffin wax, &c. It is a little doubtful if any of them will render the prints so transparent as they would albumen ones by reason of the baryta coating with which the paper itself is coated.

PREVENTING UNMOUNTED PRINTS CURLING.—G. DAVIES says: "Can you inform me of a method to prevent unmounted silver prints curling when dry? I notice that views, &c., published abroad show no tendency to do so. Can you oblige me with the reason?"—The prints referred to are usually kept flat while drying—i.e., drying between blotting-boards under pressure, and then heavily rolling on a steel plate. If the prints are squeezed on talced glass, and allowed to dry on that, they will have little tendency to curl afterwards.

UNDER-TIMED NEGATIVES.—R. BEST sends a couple of negatives as a sample of what he took on a recent Continental trip, and says he has "about a gross more plates to develop, but they have all had about the same exposure. With what have been developed pyro ammonia was used and the development much forced, which has caused staining."—The plates are much under-exposed. We should recommend the metol-hydroquinone developer, as given in the ALMANAC, to be tried, using it somewhat diluted, and with plenty of patience.

COPYRIGHT.—Z. Z. Z. says: "I have to-day had brought me a 12×10 to reduce to half-plate. It has not so much as the name of the photographer on it, but I find in your issue of to-day that it is registered. The members of the band have paid for a 12×10 copy each; some of them wish me to produce a half-plate size to send to their friends, agreeing to take a certain number. Can I do it?"—In reply: No; not if the person registering the photograph was not paid for it. The copyright is his. We have had no previous query from you.

WORKING UP PLATINOTYPES.—BLACK AND WHITE says: "Could you advise me the best way of touching up platinotypes—what materials to use, &c.? Are there any handbooks published on the subject?"—Only the ordinary water colours, such as are used for other photographs, are necessary, such as Indian ink or ivory black modified with a little blue. There is no work specially devoted to working up platinotypes published. They are treated just the same as any other kind of photograph, and the paper is better to work upon than most others.

DRYING PRINTS. ACTINOMETER.—ACTINOMETER says: "Could you kindly reply to the following questions? 1. A few days ago I dried some prints (P.O.P.) with methylated spirit, and there did not seem to be any harm resulting, but perhaps some bad effect may show itself afterwards; so, does it injure prints of any sort to be dried with methylated spirit? 2. I am thinking about getting an actinometer, but I believe the actinometer has to be exposed for a much longer time than the plate; and, as a plate sometimes requires an exposure of a quarter of an hour in interiors, it seems to me that the actinometer would have to be exposed for a very long time indeed, some hours perhaps."—1. If good methylated spirit be used, no harm will result, but we should advise it to be free from the mineral spirit. 2. Directions are supplied with the different actinometers to meet such cases as those referred to. Get prospectuses of them from those who supply them.

LENS QUERY.—PORTRAIT LENS says: "Would you kindly say if you know Janin, Paris, lens-maker? I have an offer of a portrait lens, five inches diameter; it has a rack for focussing and another rack to separate the back and front lenses near and distant; is it the same principle as Dallmeyer has on his B lenses? Would it, do you think, be useful for large heads? It has no stops. What I really do not understand is the second rack for separating lenses. Thanking you in anticipation."—In reply: The lens is a very old one, as that form is not made now. The object of separating the lenses is to alter the equivalent focus and, at the same time, to an extent flatten the field, but only at the expense of astigmatism. It will, we expect, be found to work at its best with the components in their normal position. The lens is not constructed on the same principle, for diffusing of focus, as the Dallmeyer patent lenses. If the lens be of long focus, we should say it would probably do for large heads.

## EX CATHEDRÂ.

THE ballot paper for the election of Judges to act at the next Exhibition of the Royal Photographic Society has just been issued. It contains the names of twenty-five gentlemen who are standing for the Pictorial Section, and nine for the Technical. Here is a complete list of candidates with the number of nominations they have received. Pictorial Section: B. Alferi (1), J. Craig Annan (5), Harold Baker (15), H. Walker Barnett (1), F. P. Cembrano (1), R. W. Craigie (1), W. Croke (1), Dr. P. H. Emerson (13), T. Fall (1), L. Fildes, R.A. (1), Colonel Gale (13), J. H. Gear (4), A. Horsley Hinton (14), J. A. Hodges (3), F. Hollyer (5), Charles Job (1), B. W. Leader, R.A. (3), Sir J. D. Linton (3), H. P. Robinson (6), J. A. Sinclair (4), G. A. Storey, A.R.A. (4), W. Thomas (2), G. E. Thompson (1), J. B. B. Wellington (15), W. L. Wyllie, A.R.A. (12).

IN the Technical and Scientific Sections the gentlemen nominated are: Captain Abney (17), T. Bolas (13), J. Bulbeck (1), Chapman Jones (18), J. W. Swan (1), J. J. Vesey (1), L. Warnerke (1), Colonel Waterhouse (1), Sir H. T. Wood (1).

In recent years no such list of nominees, containing, as this does, the names of some of the most prominent photographers of the time, has been issued by the Society, and for bringing about such a gratifying result we have the satisfaction of knowing that the prime cause at work was the attention we directed to the matter three weeks ago. We shall have more to say on the subject in future issues.

\* \* \*

It may be as well to remind members of the Society that the ballot paper is contained in the April number of the *Journal* which was issued on Wednesday. Special attention is directed to the condition that the ballot papers must be sealed in a plain envelope bearing no inscription whatever, and that the envelope in its turn must be enclosed and sealed in one which must bear upon its outside the words, "Ballot paper," and the signature of the member voting, and must be addressed to the Secretary, Royal Photographic Society, 12, Hanover-square, London, W., and posted to reach that address on or before Wednesday, May 31, at noon. Any ballot paper arriving after the time and date named or in a manner not conforming to the above regulations will be disqualified. Care should be taken that the ballot paper when returned bears not more than five names for the Pictorial Section and three names for the Technical and Scientific Sections.

\* \* \*

READERS OF THE BRITISH JOURNAL OF PHOTOGRAPHY all the world over will, we are sure, learn with regret of the very dangerous illness of Mr. W. B. Bolton. For many months past he has been bravely fighting the battle against the most terrible of all diseases by which a human being can be attacked—cancer—and at the present moment he lies prostrate and helpless. A wish for Mr. Bolton's recovery will rise in the minds of thousands who read these lines. His is a name that has been written across the pages of photographic history in indelible ink. It is nearly thirty-five years since the publication of the collodion emulsion process associated with the names of Sayce and Bolton. For the greater part of that long space of time Bolton's writings have had a conspicuous place in THE BRITISH JOURNAL OF PHOTOGRAPHY, of which, during the years 1879–1885, he was the Editor-in-Chief,

in which capacity his work oftentimes was of the most brilliant kind.

\* \* \*

IN the early eighties, the pages of THE BRITISH JOURNAL OF PHOTOGRAPHY were most eagerly scanned for what they contained relative to the details of the then comparatively new gelatine dry-plate process, with which, as an experimentalist, Bolton's name was perhaps more intimately associated than any other. It is hardly an exaggeration to say that the industry of gelatine dry-plate manufacture owes more to the experimental efforts of Bolton on the subject of the correct principles of emulsification than to any other man. But, indeed, there is scarcely a branch of photographic chemistry of which Bolton has failed to say something luminous, informative, and suggestive. Fortune has showered great gifts on many less deserving than Bolton, upon whose very grave illness we ourselves, who have seen the best that is in him for twenty years past, can only think with the greatest pain.

\* \* \*

THE Invitation Pictorial Section of the International Photographic Exhibition, comprising about a hundred photographs sent by forty or more British exhibitors, has, we learn, excited the very greatest interest and admiration among the Italian photographers who have seen the display. A debt of gratitude is owing to Mr. Henry E. Davis for having been instrumental in organizing the section, which has taught Italian photographers that British pictorial photography has reached a stage of beauty and variety of expression far higher than what has been attained by photographers elsewhere. In particular, we are given to understand, Italian admiration has been excited by the mastery over the various printing processes shown by British photographers.

\* \* \*

BESIDES holding its Annual Dinner on Thursday in this week, the members of the Camera Club entertained their lady friends with a lantern-slide evening on Wednesday last. The annual exhibition of members' work is now on view in the Club-room. Of its kind it is, perhaps, as good an exhibition as the room has seen. Mr. W. Crooke sends a charming full-length study of a little boy, and the refined and delicate art of Mr. H. Walter Barnett is shown in four portraits, one of which, with its conscientiously studied effects of lighting and pose, it is difficult to imagine was produced by photography. Contributions come from Mr. George Davison, Mr. Henry Stevens, and other able workers, and altogether the Exhibition is a pretty and pleasant one. Two of the most conspicuously hung portraits are, however, excellent examples of what to avoid in vignetting, and deserve to be seen on that account.

\* \* \*

WE hear upon the best authority of the discovery of a new transparent substance which is claimed to possess properties suiting it for the manufacture of photographic films and other articles. The new substance is named Flexoid. It is textureless, flexible, does not expand, contract, or buckle when wet, is not acted upon by the ordinary photographic developing and other solutions, but lies perfectly flat and limp during these processes, and dries without curling. Flexoid is applicable to most of the purposes to which celluloid, xylonite, and similar compounds have hitherto been used. It can be moulded,

pressed, turned, or otherwise treated. It is stated to be free from gun-cotton, camphor, gelatine, or collodion. It cannot ignite spontaneously in the lantern, and hence should solve the long-desired solution of a fireproof film for cinematographs.

\* \* \*

THERE will be no Paris Photographic Salon this year. The galleries in which the Photo-Club de Paris have hitherto held the Exhibition are not available this summer, and efforts to find suitable premises elsewhere have been unsuccessful. In these circumstances the Committee of the Club notify that the next Exhibition of the Paris Salon will not be held until the year 1901, the great Exposition of 1900, of course, blocking the way of an Exhibition next year. We are not confident of the survival of the "photographic Salon" idea for three years without the stimulating fillip of an exhibition, and this both at home and abroad. However, the news we have given will be interesting to English exhibitors, who will know that they need not trouble to prepare anything for the Paris Salon for a couple of years.

\* \* \*

THE Assistant Secretary of the Royal Photographic Society asks us to remind the members of the Society that the next sitting of the Fellowship Admissions Committee will be held on Monday, May 8, and that all applications for consideration at that meeting should be in his hands by that date.

\* \* \*

MAY-DAY brought us from the office of the *Art Journal*, 26, Ivy-lane, E.C., the familiar annual, *Pictures of 1899*, which consists of reproductions of many of the pictures hung at the Royal Academy and other exhibitions. The volume should be found useful for reference by those interested in the year's art, and many a photographer might find it advantageous to purchase it for the purpose of informing himself of some of the latest phases of painting and sculpture. It is noteworthy that this year our splendid contemporary, the *Art Journal*, completes the fiftieth year of its existence. A special Jubilee reissue of the publication in twelve monthly parts is announced.

\* \* \*

FOR the Gleeson-White Fund, to which we made reference a fortnight ago, Mr. H. Walter Barnett sends us a cheque for 17. 1s. We shall be happy to receive further contributions to the fund and forward them to the proper quarter.

\* \* \*

WITH reference to our last week's remarks on the imminent removal of the Royal Photographic Society to its new premises at No. 66, Russell-square, a happy suggestion has been made to us that the occasion should be signalised by some little inaugural function in the nature of a housewarming. For the first time in its history, it takes possession of a worthy and permanent home, and it is felt that an event of such interest and importance deserves a little celebratory notice. It is put to us that if the President, Lord Crawford, and the Council were "at home" one evening to the general body of members, a large number of them would be present for the purpose of viewing the new premises. Possibly music and light refreshments could be provided, and the occasion thus be made a pleasant little function. These suggestions may be worth the notice of the Council.

## THE PROJECTED COPYRIGHT ACT.

IN the House of Lords, on Friday last, the new Copyright (Artistic) Bill, to which we made allusion in our previous issue, was read a second time, and then referred to a Select Committee. Lord Monckswell, its promoter, in moving its second reading, referred to some of the differences between the proposed Act and the present one, and made a point of the fact that it had the warmest support of the Royal Academy. It will be remembered that a new Copyright Bill was introduced in the Lords last session, but it came to nothing; so indeed had several others that had been projected in previous years. Strong comments have from time to time been made that these Bills have all been framed more in the interests of painters than in those of photographers, and therefore the latter should watch their particular interests in the matter.

As the new Bill has now been printed and issued, it will be well to point out its most salient features as affecting photography, and compare them with those existing in the present Act. The Bill is entitled, "An Act to simplify and amend the Law relating to Copyright in Artistic Works," and, if it passes, is to take effect on the first day of 1900. In the Bill a distinction is made between works of fine art and photographs. This may possibly wound the *amour propre* of some of the "Salonistic" school, though it must be admitted that recent exhibitions have failed to establish a claim to photography being a fine art in the true sense of the term. However, we do not imagine that the majority of professional photographers will care very much about this distinction in the Bill; what most concerns them on this point is the duration of the copyright in their works.

In the Act of 1862—the existing Act—photographs and paintings are dealt with alike. In both cases the copyright endures for the life of the author, and for seven years after his death. In the proposed Act copyright is dealt with in three classes. The first is "works of fine art," which comprise paintings, drawings, engravings, sculpture, and other artistic works; the second, photographs; and the third, casts from nature. In the first class the copyright is for the life of the artist and for thirty years after his death. Here is a decided prolongation of the copyright. In classes 2 and 3 it is for a period of thirty years from the first day of the month of registration. This seems a little vague when taken with subsequent clauses. The duration in these classes may be a longer or a shorter term than at present, according to the life of the author. If he dies shortly after the production of the work, it would be longer; but, if he died thirty or more years after, it would, of course, be shorter. Any how, it is to be for the definite period of thirty years, neither more nor less. We opine that the value of copyright in the majority of photographs is not very great after the lapse of thirty years, though it is different with paintings.

Registration, it seems, is not necessary by the author, the copyright being his sole property; but registration is compulsory where the copyright is assigned to another, and the assignment must be in writing. The registration in this case must be effected within six months of the assignment, or the copyright becomes null and void. An important point in the present Act is that the copyright is vested in the author, and it was decided, in the celebrated case of *Nottage v. Jackson*, that the author was the one who actually took the photograph, even though he were an *employee*. In the new Bill it is provided that, when any person employs another for a valuable

consideration to make any photograph, or assists in making one, the copyright is to belong to the employer as if he were the author of the photograph.

In the case of portraits taken for a valuable consideration—though what is a valuable consideration is not specially defined—the copyright is still vested in the author, but he is not entitled to make any copy thereof, or sell, distribute, let on hire, or exhibit such work without the consent in writing of the owner of such portrait. The owner is to have all the rights of an owner of copyright to prevent infringements and to obtain the seizure of copies dealt with; and it will not be necessary, in order to enforce such rights, that the portrait be registered.

With regard to infringements, the infringers will be liable to an action for an injunction to restrain and for damages, and an account of all copies sold, as at present. The penalties will, however, be heavier than now. At present it is limited to ten pounds for each copy, but, according to the new Bill, it is to be twenty pounds and twice the sum for which each copy was sold, and, in addition to this, the taxed costs as between solicitor and client; also all the negatives, plates, &c., are to be forfeited and destroyed, as at present. Any court of summary jurisdiction is to have the power to grant warrants to search any house, shop, or place—on sufficient ground for it being shown—and make seizure of any infringements if found; also any constable will be empowered to seize, on a request in writing from the owner of the copyright or his agent, any pirated works in the possession of hawkers. For fraudulently affixing any person's name to a work of fine art or photograph, who did not produce it, with the intention to defraud, the punishment is to be very severe—imprisonment not exceeding six months, and forfeiture to the person aggrieved a sum not exceeding one hundred pounds. In the supplementary conditions and definitions of the Bill, the expression, "photograph" is to include negatives or positives and any copies made therefrom.

The expression of copy is important and well defined, and we here quote it in full. "The expression 'copy' shall, subject to the provisions of this Act, mean any representation or reproduction of a work, or any part thereof, or the design thereof, in the same or any other form, and in any material and any size, and shall include a reproduction of a picture by a sculpture, or a sculpture by any other work of art, and a representation of a picture or sculpture by a living picture." In the memorandum to the Bill the case of *Hanfstaeigl v. the Empire Palace* is specially cited. Had this Bill been law a few years ago, thousands of pounds would have been saved in litigating this case.

In the above we have simply referred to the more important points of the proposed Act as it stands as affecting photography, and withhold any criticism upon it for the present. The Bill may, of course, be very materially altered, amended, and modified before it passes into law, if it does do so. As we have said, the Bill is printed, and may be had at the Queen's printers—Eyre and Spottiswoode's—for the small sum of 2½d., and those interested in the subject will do well to get it.

**On Varying Qualities of Limes.**—The well-known varieties of effects brought about by the use of different kinds of limes for the oxyhydrogen light in lantern work seem capable of being increased by the addition of another important variety. M. Henri Gautier described the thermal effects obtainable by limes prepared in the electric furnace. Naturally the extent to which the

electric action was permitted could be varied or arrested to any extent, and so possibly a valuable new lantern adjunct produced. Working with the furnace at its best, M. Gautier obtained pieces that were so slowly acted upon by water that their specific gravity could be taken in that liquid.

**New Actinic Photometer.**—At the same meeting of the Paris Academy of Sciences to which M. Gautier described his lime experiments M. Charles Henri gave an account of his new instrument, entitled as above. Its action is founded upon the luminosity of phosphorescent zinc sulphide and the intensity or nature of the exciting sources of light.

**Diffraction of Rontgen Rays.**—Up to a recent date it has been generally held that the X rays could not be, and had not been, diffracted; but Professor Haga, in the name of himself and Dr. C. H. Wind, has shown that diffraction can be produced, as in the following method. The Crookes tube was placed behind a slit 1 cm. high and 14 microns wide; at 75 cm. from the latter was placed the diffraction slit, which gradually diminished in width from 17 to about 2 microns. The dry plate was placed at a distance of 75 cm. from the diffraction slit. The plates were exposed for times varying from 100 to 200 hours. The image of the slit, at first narrower, gradually and unmistakably became broader. From the width of this slit, corresponding to the broadening and the character of the latter, an estimation of the wave-length of the rays can be made. The experimenters found the rays to consist of from 0.1 to 2½ Angström units comprising four octaves.

**The Use of Kites.**—We have several times referred to the position attained of late in the science of kite-flying and its possible adaptability to photographic purposes, and our attention has been again called to the matter by observing in a scientific contemporary a query as to the proper mode of constructing such a kite and the suitable gauge of the pianoforte wire to be used as the "string," the purpose of the inquirer being to send up the kite with a camera attached. Bulletin No. 3 of the Blue Hill Observatory gives an excellent *résumé* of the kind of work done during the last two years. An early record was Mr. D. Archibald's, he in this country having sent up, to a height of 1500 feet, a kite with anemometer attached. Mr. W. Eddy a couple of years later invented a kite which ascended 2000 feet, until at last, in America, the last two years' efforts have culminated in the attainment of a height of 10,000 feet for a kite with self-acting meteorological instruments attached. Last February, they topped the record at 12,507 feet. Kites are cheaper than balloons, and the instruments can be better actuated from them than from the latter. It would therefore appear that there now only needs the advent of a suitable camera with self-exposing apparatus for the photographic method to become an actual success.

**Permanency of Aluminium.**—An opinion prevails that aluminium is not put to the uses it might be in photography, and certainly the advantages it offers, by reason of its extraordinary lightness, are so very great, that it is small wonder, especially as it now is obtainable at such a cheap rate, that opportunities should be sought for further utilising it. One great supposed drawback is its alleged want of permanency. We have been credibly informed that cases are frequent in which it has been known, when exposed to the atmosphere, to "shell away," and we have the record of the French Commission, who examined this question with considerable pains; they gave an adverse verdict. But two points militating against the acceptance of the verdict must be borne in mind. First, the metal is now procurable in a far purer form than at the time the Commission sat, so high, as M. Moissan recently pointed out, at a sitting of the Paris Academy, as 97.8 per cent. against a mean percentage 93.4, which was its record about five years ago. Again, referring to the quick disintegration of drinking vessels used in Madagascar, M.

Moissan points out that this may have been expedited by the utensils having been mounted in iron, and so a galvanic action having been set up; and this, as every one knows, is fatal to metals like aluminium. With regard to the use of this metal for developing dishes and the like, account would have to be taken of its behaviour to chemicals. Thus, concentrated nitric acid will not act upon it; but, contrariwise, it is readily dissolved by hydrochloric acid. It is also readily acted upon by solutions of caustic potash or soda, though not to the same extent as with hydrochloric acid.

### SPEED SCALES.

THERE is a very good opening for a series of articles on the speed scales now in use. I have computed the enclosed comparative table, which is as near as I can get it from the data before me; but such data are not always of a satisfactory nature. The following is a quotation from the *Instructions for the Use of Hurter & Driffield's Actinograph*:—

"The Speed Scale.—The speed of the plates as marked on this scale has no relation to the arbitrary and unreliable speeds generally spoken of, but is based upon scientific principles and upon clearly defined units. We define the speed of a plate as that exposure, expressed in seconds, which, with one actinograph degree of light, will produce a theoretically perfect negative of an ordinary landscape, the light reaching the plate being equal to that reflected by the objects. The marking of packets of plates with their actinograph speed will be a very great boon to photographers, if only because the exposures the plates will require will be exactly proportional to the speed indicated."

The above appears to be very clear and rational, and I understand from it that if a packet of plates marked 10 required one second exposure, another marked 20 required two seconds, and so in proportion; but all this is expressed by the example which is given thus:—

"If, for example, a photographer has worked successfully with some plates of which the actinograph speed was 10, and the next packet he procures is marked 20, he will at once know that the latter requires just half the exposure of the former, because twice as rapid."

EXPOSURE TABLE.

Proportionate length of Exposure.	Hurter & Driffield's Notation.	Watkins' P Number.	Wynne's Meter.
6	166.66	250	f.115
7	143	214	f.106
8	123	188	f.99
9	111.11	166.66	f.94
10	100	150	f.89
20	50	75	f.63
30	33.33	50	f.51
40	25	37.5	f.45
50	20	30.0	f.40
60	16.66	25.0	f.36
70	14.3	21.4	f.34
80	12.5	18.8	f.32
90	11.11	16.66	f.30
100	10	15.00	f.28

This is difficulty No. 1. The scale used in the Watkins meter is clear, and the column of proportionate exposure is calculated to correspond with it.

Returning to the Hurter & Driffield meter, I find, from Mr. Watkins' Relative Speed List, that some firms mark their plates with H. & D. speed numbers, but that the speeds denoted by the same number vary according to the make as 1 to 1½ and 2½ (approximately). This difference, I understand, is due to the developer used in testing the speed. In compiling the table I have taken the value of the H. & D. meters at two-thirds of the Watkins' plate-numbers. The last column is calculated from the H. & D. column in accordance with the data given in Mr. Wynne's List of Plate Speeds.

Ought not this matter to be taken in hand by the Royal Photographic Society, and a uniform system of testing and marking recommended? My own view is that the numbering should be in direct (not reverse) proportion to the exposure required. This has been done in the case of apertures.

CHARLES LOUIS HETT.

## AMMONIUM PERSULPHATE—ITS PROPERTIES AND USES.\*

8. BESIDES a neutral solution, Namias also tested a solution of ammonium persulphate, made alkaline by the addition of ammonia, and found that such a solution acted only very slowly as a reducer, and required an hour and more in order to obtain the same effect which is given by the neutral solution. If a solution of persulphate made alkaline by the addition of ammonia is mixed with a solution of silver nitrate, there will be no precipitate even after a long time, and even after some hours the mixture remains as clear as water. Nevertheless, the alkaline mixture exerts a reducing action on the image which is quite equal to the plain solution, but it requires a longer time.

Whilst the phenomena stated above prove that the explanation given by Lumière and Seyewitz is untenable, they lead to the conclusion that the inferior reducing action on the surface of the image-bearing film (namely, the deposition of the subsulphate of silver) is not the only and the principal action; what the latter is, is at present unknown.

9. Besides the use of ammonium persulphate as a reducer, there are other applications in photography which are not less important.

In the first place it is undoubtedly the best method to reduce yellow stain in negatives, and it is considerably more effective than thiocarbamide, which is so often recommended for this purpose.†

Ammonium persulphate acts quickly on the freshly made and also on the old negatives. Either a one per cent. or, at the most, a two per cent. solution should be allowed to act, and this takes from five to fifteen minutes; the negatives should then be placed at once in a five per cent. solution of sodium sulphite and then washed. The persulphate destroys and removes the substance which forms the yellow stain, and converts any silver in the yellow fog into silver sulphate.

Persistent yellow fog or yellow spots in the negative, caused by the fixing, require a prolonged action of the persulphate, and even if in a weaker solution a reduction of the image will take place. If a solution made alkaline with ammonia be used, there is no reduction during the time necessary to remove the fog.

10. Ammonium persulphate may also be used for the reduction of negatives which have been intensified with mercury, cyanide, which has hitherto been recommended for this purpose, being unsafe. Negatives which have been blackened with sulphite are specially suitable for this purpose. In this case the image consists partly of metallic mercury, which is converted into sulphate according to the following equation:—

12. The property of the persulphate of dissolving the silver of the image may be used for making positives direct in the camera or may be used for the preparation of duplicate negatives with advantage.‡ The negatives, which should be fully exposed, should be treated with a developer with plenty of bromide till the image is plainly visible on the back. It should then be washed and immersed before fixation in a five per cent. solution of persulphate and left till the image has entirely disappeared, which will be in about twenty minutes.

It is advisable to mix the persulphate with some alum solution in order to counteract the solvent action of the former on the gelatine, and for the same reason also the strength of the persulphate should not exceed five per cent.

The film after this contains only the silver bromide not reduced by the developer which corresponds to a positive image. After washing, the plate should be exposed to diffused light for from twenty to thirty seconds and then blackened in the developer. For this second reduction the ordinary negative developer is hardly energetic enough, and therefore Namias adds to every 1000 parts of the ordinary hydroquinone developer at least 10 parts of caustic soda. This method for the production of positives is much simpler than all that have been hitherto recommended; it can, however, give failures as well as those if not properly worked. In order to obtain clean images, the development must, as has already been mentioned, in the high lights be carried on right to the glass.

On the ground of the notable action of the persulphate on the silver image, it was feasible to assume that it would not be without influence on the latent image; and, as a matter of fact, Namias has been able to confirm that an exposed image after a five minutes' treatment with a two per cent. solution of persulphate has entirely lost the power of being

developed. A shorter time of action only weakens the image, so that it is quite possible that use of this property might be made to reduce the action of over-exposure. The few experiments which have been made however, do not allow a definite conclusion on this point.

13. The property of the persulphate of converting the chromous oxide into chromic acid enables one to use it for the development of over-printed bichromated gelatine films in which the ordinary means are of no use. For this purpose a five per cent. solution mixed with one per cent. of sulphuric acid should be allowed to act for half an hour or longer, and then development effected with lukewarm water. The persulphate, in the presence of the sulphuric acid, oxidises and partly dissolves the insoluble chrome gelatine or albumen, so that the same will dissolve more readily in lukewarm water.

Namias believes that ammonium persulphate could also be used for the restoration of spoilt pigment paper, but no results have been made.

14. A very important application of the power of the persulphate to dissolve metals may be made. It has already been mentioned that persulphate will dissolve zinc, converting it into sulphate without the evolution of hydrogen. Experiments have proved that persulphate gives far more even results when used for etching zinc for half-tone work than any acid, and that its action is very like that of ferric chloride.

It was found, however, that there was still a small evolution of gas when the persulphate acted on zinc, even when the solution was made alkaline with ammonia. This latter fact appears to exclude the assumption that the gas that is set free is merely hydrogen caused by the action of the sulphuric acid, which is formed by the spontaneous decomposition of the persulphate, on the zinc.

Perhaps the zinc decomposes part of the persulphate which may not take part in the reaction, so that the persulphate extracts the hydrogen from the water and sets free oxygen, as has been noted elsewhere.

Whatever it is, there is no doubt that an etching solution, which, like ammonium persulphate, acts in a neutral or alcoholic solution, and which causes only a faint evolution of gas, will be very advantageous for the regular process of etching, and probably may make the burning in of the insoluble bichromate film for the protection of the drawing during etching quite superfluous. The bichromate film made insoluble by the action of light alone may prove by itself to be sufficient protection, so that the burning in, which is so prejudicial to the zinc, may be obviated.

Aluminium is attacked in a similar manner as zinc, so that, when this metal is used as a substitute for the litho stone, this etching solution ought to be the most suitable.

Copper is also attacked by ammonium persulphate without the evolution of gas, and the more alkaline it is made the stronger it acts, so that in many cases the persulphate may replace ferric chloride.

15. For positive work on printing-out papers the persulphate is very useful as a reducer. As a neutral solution acts too energetically, Namias uses a one per cent. solution of persulphate to which one per cent. of ammonia is added. The prints may be reduced before or after toning or after fixing. The prints should be well washed, and, if treated after fixing, they should be treated to a subsequent bath of sodium sulphite of one to two per cent. strength.

The use of an ammoniacal solution is also to be recommended on the further ground that a neutral solution may cause a slight deposit of sulphur.

16. If a bromide print is wanted in a hurry, it should be superficially washed and then bathed for about five minutes in a one to two per cent. ammoniacal persulphate solution; the persulphate oxidises the hypo, and during the short immersion that is necessary there is not likely to be any reduction.

The same solution may be used for the removal of yellow stains which sometimes occur on bromide prints. If the print is to be reduced, the ammonia should be omitted.

The persulphate seems to have no reaction on platinotypes.

17. Finally, another useful application of persulphate is in the restoration of old silver paper that has turned yellow.

Namias found that gelatino-chloride paper, which after four months' keeping had become quite brown, became quite white by a few minutes' immersion in a two per cent. solution of persulphate rendered faintly alkaline with ammonia. When the paper was dried and printed under a negative, good prints were obtained, but of somewhat less intensity than with the fresh paper; but this loss can be avoided by adding two per cent. of silver nitrate to the persulphate. Paper thus restored gave quite as beautiful and vigorous prints as fresh, so that the problem of restoring old paper has been solved.

\* Continued from page 232.

† The use of ammonium persulphate for this purpose was also suggested first by R. E. Liesegang.—Trans.

‡ This was pointed out also by R. E. Liesegang.—Trans.

## BACKGROUNDS, MOUNTS, AND FRAMES.

[Paper read before the Photographic Society of Philadelphia.]

As we must make a picture before we frame it, the subject of backgrounds comes at once into the foreground. It readily divides itself into two classes—natural and artificial. Let us look first at the former.

Theoretically, nature always provides a perfect background for any natural picture. The broad expanse of a landscape, the rich colour values of a sunset, the delicate tracery of winter-dressed trees, the flash of a scarlet flower against its mass of green foliage, need no assistance. The picture is there, can we but find it. It is when we begin to twist nature to our own ideals that the background becomes of importance. Of how much importance, let the impious professional "artist," who poses the peanut-eating tourist of a day, with his "Marlar" held tightly by the hand, against the majesty of Niagara as a background, tell! It is important to him, sure enough; and his efforts are apt to cause a sincere regret that his tintype machine is not a back-action dynamite bomb, warranted to destroy both ways at once.

But the thing for the photographer to consider first, in using a natural background after he has selected or composed his picture, is the matter of contrast. If his effort is being expended on a group of people outdoors, he must decide whether he will have the group major or minor—whether it will contrast with and dominate the composition, or whether it shall harmonise with the natural surroundings, seeming an incident of the time and place. The latter form is the most satisfying when well accomplished, and certainly much the more difficult of accomplishment. But either one or the other form must be resolved upon—a medium course is mostly well on the way to a mess.

Contrast in backgrounds is easily accomplished, especially in these days of wide-angle, fixed-focus, hand-camera lenses. Witness your fisherman friend, whose tremendous catch, held directly toward the lens, hasn't lost anything of apparent size because compared with the human background.

Contrast, however, properly managed, is most desirable. To pose the group so that a clump of dark foliage is back of it, or, again, to have the salient figure of a composition so that a cloudy sky gives it life, is very satisfactory. But my talk must not trench too much upon the deeps of the subject of composition. Let me but briefly call attention to the harmony of green fields, of broad lawns, of wind-swept meadows, as backgrounds for any artistically arranged outdoor picture. The medium tones, photographically, of sward, lawn, or leaf-strewn surface, blend most delightfully.

For superb contrasts, take account of the background effects of solid masses of green foliage. It is Alfred Stieglitz, I think, who has so successfully used foliage masses in outdoor portraiture. Much study may profitably be given to this branch of our art.

In passing from the consideration of outdoor or purely natural background effects, I want only to drop one word of technical warning against the use of too small stops in landscape work. I recently saw a photograph printed as an advertisement of a modern lens, which showed microscopic definition all through. There was no background—it was all foreground, and the mountains in what was intended to be the distance seemed to be cut out of tin, like a pie-crimper. I am not in love with fuzzy impressionism, but there are extremes in the other direction.

The artificial backgrounds are likely to be far more troublesome. Years ago they were easy, apparently, as any one may see in looking over old studio photographs. All that was necessary was to bring Mr. Reuben Hayseed, who wanted his picture took, into the gallery, pose him against a Louis XIV. chair, with a large red hand carefully spread out, his rotund face solemnly staring into the camera, and a fine marble staircase fading away into the background, showing, of course, the perfectly accustomed surroundings of our rural friend, and the thing was done!

Nowadays, the portrait professional has a most perfectly appointed studio, with various artistic backgrounds, which some of them know how to use. With his work we need not concern ourselves, but rather with what we can do in such work as the amateur undertakes.

It may be enunciated almost as a cardinal principle in seeking backgrounds for portraits or any other photographic work of an artistic, not technical, nature that extremes are to be avoided. A pure white sheet and a flat black surface are equally objectionable, though both may serve the purpose of the artist who understands alike their value and their danger. Indeed, there may be this one thing concerning the whole subject of backgrounds, mounts, and frames, taken as a primary fact, that the photographer must decide between harmony and contrast. There is always harmony in a well-managed contrast; but the difficulty of obtaining it indoors points the amateur to the wisdom of working first along the easier and scarcely less charming path of colour harmony without violent contrasts, until he may deem himself ready to take up the masterly methods of a Rembrandt.

For our familiar photographic work, then, we want background materials. With the principle of colour harmony before us, and the not less important thought that the background must remain a subsidiary feature, we can always work with reasonable certainty. I remember a sharp reminder I had some years ago, when a portrait was attempted in

an hotel room, without considering the wall paper. When the negative was developed, the lurid display on the wall fairly swallowed the sitter!

In arranging for a home group of the children at play, for instance, the main care as to background must be to avoid the hard lines not only of windows, but of varnished doors and furniture. In this case we want familiar surroundings, but we don't want a picture of a door with human accessories.

Simplicity is also of the utmost importance. Photograph something, but not everything; don't let your background smell of the "junk shop," or seem to be a mere gathering of *tric-à-brac*.

For the work indoors, or with artificial backgrounds, a study of the colour value of various materials will be exceedingly useful. Make a negative of pieces of all the cloths or papers you want to consider, from black velvet to a white sheet, and notice the various gradations.

Take account also of the lighting of your background. A pure white surface may be so managed as to show a gradation of shades, and a black cloth will reflect a surprising amount of light. Glossy surfaces are hard to manage, but capable of fine effects when under control. Again, remember the importance of depth, or "atmosphere," and don't have microscopic sharpness in the background.

Passing now from the consideration of the details incident to the making of a picture, we come to its after-treatment in mounting and framing. It is hardly necessary to say that the sole object of the mount and frame should be to bring out the salient points of the picture. Neither should be conspicuous, or in the least detract from whatever attention the picture deserves. Every one present can call to mind, however, numerous instances in which the contrary is the case. While it may often be assumed that, if the frame or mount is more conspicuous than the picture, the latter is not worth bothering with, there are too many instances wherein a badly chosen mount or frame has spoiled a really fine photograph or painting, to make the assumption a rule.

In no part of the photographer's work is it more important that the underlying principles be understood than in this. At the risk of challenge, I shall attempt to reiterate the vital principle governing the whole matter of mounting and framing, which, when fully grasped, renders easy the proper handling of what has been difficult to many of us. It is simply this, there must be either colour *harmony* or well-balanced complementary colour *contrast* between the picture and its mount and frame.

Happy is he who can safely and successfully arrange contrasting colours, and who is able to decide just the amount of complementary shade his picture will balance in the frame or mount! As for me, while I have once or twice stumbled into a good result in contrasts, I breathe far more freely on the safe ground of colour harmony, and will be satisfied to work up through to the higher knowledge. Though it may be well to hitch your wagon to a star, the axles will be far less liable to screech as you get along if they are lubricated with the oil of patient endeavour and intelligent, progressive practice.

Why does a platinum print look well with a Rembrandt mount? Why did black oak frames at the Salon seem just the very best setting for little gems of black and white? Simply because in both cases perfect harmony exists between the picture and its immediate environment? Look at any sepia or brown photograph on a white mount, and you see a lack of harmony. Call to mind the lovely \$1.49 department store crayon enlargement of a cabinet photograph, in its gorgeous gilt \$3.98 frame, and the very antithesis of the right thing is before you. Any black-and-white picture is damaged by a gilt frame, because there is no harmony and no correct contrast. If you must use shiny metal, a little silver line will not hurt the platinum or Velox print, simply because it is relatively white, and thus in harmony.

Following this principle to its application, we see many delightful opportunities. Do you print with Velox, and will the bromide turn your blacks greenish-brown? Don't scold; get a deep olive mat, and a frame with a dash of green, and you have enhanced the beauty of your picture. So also with other photographic tones, if they are matched in the tones and colours of the mat and frame, the result is almost certain to be pleasing.

In passing, let me suggest for consideration a new frame material, which I thought was an original scheme of my own until I found some one else had also originated it. It is simply book cloth, such as you see on the modern publications, and which comes in a great variety of shades and textures. It may be covered over wood, but I have had much interest in evolving frames made of binders' board, or tar board, covered with this cloth. The frame is flat, of course, and therein lies a merit, for its wide surface affords an excellent surface for what might be termed extra illustration. A dainty sketch in one corner, in an harmonious tone, of course, or a twig of foliage in outline, and there results an individual frame, carrying out the real thought of the artist as to the picture and its environment. These frames may be made by any one who has patience, glue, and some ingenuity, and are by no means expensive.

So far I have thought and spoken mostly of the mounts and frames for photographic work. A concluding moment may touch upon the handling of water colours and other art mediums. There is no change of principle here; it is harmony that gives the most agreeable results, unless you may hit upon proper contrast. The prevailing tint of the

picture must govern or complement the frame and mount. I have a delightful little reproduction of one of F. Hopkinson Smith's water colours of Venice. It is green water, blue sky, and a dash of high colour in the garments of the figures. I chanced upon a dark olive mat, and a deep green oak frame, and the whole thing became harmonious. I had hit the complementary contrast; and, observe, there was no gold used, either in mount or frame. This substantially upset a dictum I had been given some years ago in New York, that "water colours must always have gold mats."

Again, I have a De Longpré peony bit, a riot of reds and pinks, done with his inimitable grasp of nature. I dared not try contrast, so the frame is one of flat binders' board covered with deep red book cloth. In the slang phrase of the day, "It's all right!"

But it is unnecessary to detail practice. The one principle which is about the only grain of wheat in all this chaff is that repeatedly stated, that harmony between picture, mat, and frame must prevail, either by shades of the same colour or by skilful contrast. This principle is so simple that any one may grasp it and use it, and yet forty out of fifty photographers, and ninety-nine out of a hundred makers of picture frames, neither know nor practise this fundamental principle, or else they use it unconsciously, and thus ineffectively and uncomfortably.

J. HOWARD McFARLAND.

### BALLOON PHOTOGRAPHY.

THURSDAY last week found the members of the Camera Club assembled in goodly numbers to hear a paper by the Rev. John Bacon, whose name has recently been much before the public in connexion with certain experiments in meteorology, which he has been making by means of a balloon. The subject covers much that is new to the Club, and was especially interesting to the members, for the reason that it had a distinct photographic tone. Mr. Bacon and his daughter, who shared in most of his experiences, are both ardent photographers, and the various details connected with many ascents were consequently well illustrated by lantern pictures.

Mr. Bacon prefaced his subject by remarking upon the difficulties of making accurate aerial records, and a common tendency to overstrain a point when no real justification existed for such a course. And to emphasise this he reminded his hearers of the nervous curate, who in speaking of the fatted calf, described the animal as of special importance in having been "fattening for years."

The lecturer acknowledged the merits of those observations made in 1862 by Glaisher and Coxwell, who did wonderful work considering the resources then at their command. He also referred to four noteworthy ascents made by Mr. Welsh, of Kew Observatory, all of which showed one marked characteristic which seemed quite independent of cloud or sunshine. On each occasion he came to a certain stratum of air where the decline of temperature received a certain check followed by a recovery. Three typical diagrams made by Glaisher, during the ascents already adverted to, showed a similar state of things, the check taking place at a height of about 4000 feet. Recent experiments in America with kites proved that there was the same curious check and recovery. Mr. Welsh imagined that this change of temperature, in an unexpected direction, was caused by a kind of aerial gulf stream in the upper atmosphere.

The lecturer now began an account of some of his own experiences in cloudland, the first ascent which he described taking place from the Crystal Palace, Sydenham, at 10 p.m., under the beneficent beams of a harvest moon. On this occasion he took with him an air thermometer, the usual cased instrument not responding quickly enough to small changes of temperature. He found that there were places in the air where the temperature was warmer by 15 degrees than it was on the land below. This led him to suspect the presence of floating volumes of air, or water vapour over certain localities, and he believes that these invisible clouds affect both light and sound phenomena.

During last season the lecturer made ten balloon ascents, during which he made many tests of the acoustic properties of the air. By blowing a horn he was able, by listening for the echo from the earth's surface, to find out whether the air was acoustically transparent or opaque. Such different conditions did not seem to affect the operation of taking a photograph on the ground, and he showed a couple of pictures taken in India, one on a very dry day, and the other when the air was saturated with moisture, and both were equally brilliant.

Then came the pictorial description of a balloon ascent from start to finish. First, we saw the balloon flaccid and empty lying like a big round mat on the grass, surrounded by sand bags attached to cordage. Half an hour later, the monster has half risen from its bed, and looks like a gigantic dumpling. The next picture showed the balloon three parts inflated and ready for the ring to be fixed in position. One more picture shows the machine ready to rise from the ground directly the word is given to cast off.

Next came a series of most interesting photographs taken from the car as the aerostat rose from the ground, the pleasure-seekers—the ascent took place at the Crystal Palace—looking very tiny and curiously foreshortened. Another view showed the human dots getting smaller and smaller, until they are quite out of sight, and a mass of roofs take their place.

"From the moment of starting," said the lecturer, "the balloon does not move, nor do you feel a breath of air. But the earth behaves very differently. First it flops down suddenly, and presently begins to solemnly turn round and round."

Upon this occasion the air was so still that the heavy grapnel was left behind as a useless incumbrance. The balloon was soon above Bromley, and then it was caught in a strong north-westerly wind. The voyagers travelled along so fast by aid of this wind, that they soon came in sight of the sea. There was Beachy Head, apparently unpleasantly near. They were soon passing over Hawkhurst, and from an altitude of 8000 feet saw Hastings "approach towards them." There seemed to be only three or four meadows between them and the cliffs, and, as they had no ballast left and little spare gas, those cliffs seemed to promise disaster. All this time the captain of the balloon seemed to be in a brown study, he was looking over the edge of the car, but did nothing to avert the impending danger. Suddenly they descended into a westerly wind, they were borne along above the chimneys, and finally came down quietly in a meadow. The captain had detected this westerly current long before by watching the smoke from the Hastings chimneys, and had landed in the exact spot which he had picked out for the purpose.

Another ascent graphically described by the lecturer, and illustrated once more by excellent pictures, took place at Clifton, near Bristol, during the meeting of the British Association at that city. Here the conditions were very different, and the pictures were not half so bright as those taken during the ascent from the Palace. The aeronauts rose from the earth at five p.m. on a September evening, and soon afterwards the sun went behind a cloud, and, owing to the sudden chill, down came the balloon, in a wood. The spring of the boughs cast them off, and they finally landed quietly in a meadow. One picture taken during this ascent showed the shadow of the balloon cast a long way below on the grass, and another showed a similar shadow on the clouds.

Mr. Bacon believes that the rapidity of photographic action depends largely upon the amount of moisture present in the air. In a humid atmosphere he always secured very rapid action, but not when dryness prevailed. Under the latter state of things he never made an over-exposure.

The lecturer next referred to his experiences during the last eclipse expedition to India, and showed some very interesting pictures taken by his daughter during the period just before, and just after, totality. The pictures were each the same so far as subject went—a landscape with trees, and groups of Hindoos dotted about, "all in a mortal funk." One very curious point referred to was that the landscape five minutes after totality was double as bright as that taken five minutes before totality. The phenomenon has been noted before, but never photographed, and the common explanation given is that the eye is deceived owing to the restful period of darkness. It is suggested now, in light of these photographs, that the greater luminosity of the one last taken is due to the condensation of moisture during the time the sun is covered, and the consequent greater diffusion of light from the suspended particles. After showing some photographs taken in the Scilly Islands—where tropical conditions prevail, both with regard to vegetation and absence of twilight—Mr. Bacon described some of his acoustic experiments.

He made many attempts to sound the sky for those invisible masses of vapour which Professor Tyndall called acoustic clouds. In making sound experiments off the North Foreland, Tyndall heard distinct echoes from space, and attributed them to the presence of banks of invisible vapour. Mr. Bacon failed to obtain these results, although he used tonite cartridges, suspended 120 feet below the car of the balloon, which made a noise like a cannon. The echo from the earth came up like a deafening roar, but there was no sign from space.

Mr. Bacon's lecture was listened to with rapt attention, and his pictures were much admired. The vote of thanks proposed by the Chairman, Mr. Machell Smith, was most heartily given.

### JOURNALISTIC PHOTOGRAPHY.

MR. CLEMENT SHORTER contributes an article to a recent (April) number of the *Contemporary Review* upon "Illustrated Journalism," in which, amongst a good deal of other interesting matter, he deals with the place occupied by photography, and its future prospects. A very fair article, written by a level-headed man, evidently gifted with the saving common sense, not always the characteristic possession of many of the writers of articles in which there is an estimating of the value of photography. It is this desirable quality that allows Mr. Shorter to give its due place to photography against his evident leanings towards the work of the artist, a bias possibly acquired from, or at any rate emphasised by, his connexion with the *Illustrated London News*. Within the last nine years illustrated London journals have, he tells us, run up from five to thirteen, an increase due to photography and the substitution of mechanical processes—in turn largely due to photography—for wood-engraving. The satisfactory statement is also ventured that, whilst there will ever remain room for the artist, "photography must have an even larger place in the journalism of the future than of the past." How marked its present position in this field is may be judged from an analysis made of the illustrations of nine of the leading journals, English,

American, Italian, German, and French, of March last, in which out of a total of 328 illustrations, 213, or nearly two-thirds, are photographs. And if America's character for taking the lead, in her sharp and profitable adaptability to any newer order of things, hold good here, the probabilities of the prophetic increase referred to are strengthened when it is noted that photographs form nearly eighty-eight per cent. in the American publications given. It is very evident that there is a heavy demand for photographic work, and if Mr. Shorter be correct in his further assertion, that it is mainly the mechanical difficulty of rapidly printing half-tone drawings and photographs that bars the extended introduction of illustrated newspapers, when these technical difficulties shall have been got over, the amount of photographic illustration will be multiplied many times over.

The work of the artist must ever claim a high, if not the highest, place, and one very important qualification of the successful editor, as put by the writer already quoted, is "skill in realising the limits of the artist and the limits of the photographer." The same applies in a marked degree to the photographer himself. A very great number of the photographs at present appearing are not good ones; what must the far greater number of those rejected be like? If practicable, by the way, how interesting and instructive would be an occasional supplement both of illustrated and non-illustrated papers giving photographs, drawings, and articles rejected as unworthy of an orthodox place!

Referring to some of the difficulties standing obstinately in the way of good photographic work, and that require something of imagination to conceive as ever cleared away, there is, to begin with, the so-decided demand for strongly spiced meat; one that the camera requiring reality as a *sine-quâ-non* to work upon is at once out of the running. The unhappy sailor must be half way down the shark's throat, as it were, the bodies of the victims of an explosion be shown in mid air, the colliding trains in the actual smash, the wrecked vessel in the act of striking upon the reef or breaking in two. No camera, however well helped out at the retouching desk, can accomplish this style of thing; here is fair room, at any rate, for the artist, with his imagination, suggestion, or what not, that he is so fond of taunting his competitor the photographer with the lack of. With journals cast in quieter mould, the popular royal, commercial, or civic functions, as shown in wedding, christening, directors' meeting, or complimentary feast, are also photographically out of it. It is possible that the public may turn for its pabulum to less spicy and more nutritious directions, and that our lenses and working material generally may become so improved in range and excellence as to give the camera a chance where now useless; but, without troubling ourselves about the future, there is ample room for the accomplishment of better results all round with the power we now have at command. The praiser of times that have been in illustrated work has some room for his discontent, for, apart from the descriptive letterpress being oftentimes so evidently written up to the pictures, these are themselves not worth writing up to, the combined result being a stiff mechanical production without spring and elasticity—a concrete floor to sleep—or try to—upon, instead of a feather bed.

One of the chief causes of failure lies in not recognising what is advantageously photographable; there is an effort to gain the older effect of the sketcher and artist by means of the camera. It cannot be done, more than the flavour of freshly caught trout can be expected in a tin of potted salmon because both are fish. Still potted salmon is very good eating, and if we cannot afford the time, and lack the skill, to catch the trout, we must make the most of the other. Take a case more to the actual point in illustration. We frequently have a photographic picture of an important football match; but who can call it a satisfactory one, or to be compared in interest with a spirited sketch? Are not the players pigmies? Is not the all-important ball a dot? and does not the field run into uninteresting foreground, without even the inevitable frightened dogs snoring across it? What satisfaction is there in the whole to one who has seen the match, or a similar one? How can it compare with the rush and go of his mental picture? Well, but who can expect it, with the players twenty or thirty yards off, in constant motion, on a dull winter's afternoon? Then, why try for it, and hold that you have a picture worth printing of a football match? The illustrative aim should be in a different direction. The forward player who led the rush, the three-quarters who did the passing, the goal-keeper who defended so well, would probably not be at all averse to being photographed after the game, and the pictures could be made successes. Come to think of it, why should the convention have obtained of taking a football team always before the play in the inevitable pyramidal semicircle? Would not a picture afterwards, with the telling marks of the play upon them, be far more interesting? Although the full life and soul of the game cannot be thus presented, it is yet possible, with truer aim and a streak of luck, to catch a characteristic and telling bit here and there—a scrimmage near, or line out from, the touchline, a flash of fast play near the goal. The same applies everywhere else—the review of troops, horse race, boat race, procession, and so on. How rarely is there anything of individuality introduced into practice. Given something to photograph, will not nine out of ten set about it in the same way, from the same point of view, and turn out much the same picture in all essentials? The Editors of the JOURNAL in the number for April 14, in a comment upon the prevailing complaint of pay and treatment by assistants, hit the matter

off very sensibly by saying that "the simplicity of modern photography is responsible for flooding the photographic labour market with an overwhelming amount of mediocre ability which is usually remunerated in the exact ratio of its value. On the other hand, in photography as in every other pursuit, the law holds good that talent is bound to assert itself in the long run." Now, I take it that no mean portion of the talent referred to would consist in presenting to the camera work that, from a thoughtful predetermining, as well as technical, knowledge of its power, it could do to advantage. A very difficult task when the many limitations of the camera are taken into account, and one corresponding in kind and degree to the higher power of the artist in truly conceiving and designing his picture.

The public demands illustration of a certain event or occurrence, and that editor is smart or otherwise who can best anticipate the value of the demand, and meet it; but it should rest solely with the photographer as to the best way of conveying the desired impression. It resolves itself naturally, like everything else, into a premium upon the intelligence of a worker in a special direction; partly in a technical knowledge of what his tools can do, but principally in a broader conception of what impression the full finished result is expected to give, and giving it. It is a great pity that these two factors have something of oil-and-water character about them; they do not mix well together from some reason or other, probably a natural one if we could go deep enough to find out, for it is by no means confined to photography. The technically excellent man, from too close an attention possibly to the strict rules and formulae that have brought him his excellence, is not often disposed to go beyond, whilst the other, rich in breadth of idea and thought, regarding himself as a quart-jug man, as it were, despises rather what he takes to be the pint capacity of the other, and, from impatient disdain, does not pay sufficient attention to the more commonplace means by which only his ideas can bear profitable fruit. There are a few, very few, who have the two qualifications in an ample measure—two-quart men; I wish I were one—they are certainly the ones who will root highest in the branches of this growing tree of photographic illustration.

J. REES.

## THE ANALYSIS OF GLUE.

(*Chemiker Zeitung*.)

Two new methods have recently been proposed for the analysis of glues. Stelling (*Chem. Zeit.*, 1896, xx, 461) recommends the estimation of the non-gluey material; Fels (*Chem. Zeit.*, 1897, xxi, 55) proposes estimating the viscosity of a solution of the glue.

I have made a number of experiments to determine the relative values of these two methods, and I propose to record briefly the results I have obtained.

Stelling's process consists of adding to a solution of glue (1 part of glue to 4 parts of water) alcohol at 96°, in small quantities at a time, while constantly stirring (we take 15 parts of glue and 60 parts of water, and make up to 250 c.c. with alcohol).

We then determine the proportion of non-gluey matter present by evaporating down an aliquot part of the alcoholic solution, previously filtered, and weighing the residue. This process is thus based on the supposition that alcohol at about 72 per cent. in volume leaves the glutine intact, while it dissolves the products of decomposition, considered as non-gluey material.

I should here remark that the products meant by the term "non-gluey" should not be considered as products of decomposition of the glutine; they are also found in the original solution of glue before it has undergone any destructive process by evaporation. I would also remark that the supposition that alcohol at 72 per cent. is best for separating the glutine from the products of decomposition does not rest on any theoretical considerations, and, if we proceed exactly according to Stelling's instructions, this separation does not even take place.

Glutine is not entirely insoluble in alcohol at 72 per cent., inasmuch as, on evaporating down the filtered alcoholic solution, we obtain a residue consisting principally of glutine, and possessing a strong adhesive power almost equal to that of the original glue employed.

Nevertheless, it cannot be denied that Stelling's process has a certain value—very small, it is true—for the valuation of glues; above all, when we have to deal with products of superior quality, products containing substances soluble in alcohol, in quantities much smaller than are present in ordinary glues.

Fels' method—that is, the determination of the viscosity—can also give very useful indications, but here, again, there are certain reservations which must be made. The viscosity is determined at 25° with an Engler viscosimeter. I claim to have discovered that solutions of glue undergo, after a more or less prolonged time of standing, modifications from the point of view of fluidity. In this way a freshly prepared solution had a viscosity of 9.0°, but, after standing for twenty-four hours, it had assumed a gelatinous consistency. Another solution underwent the following modifications: its degree of viscosity was 3.7 after two hours, 4.8 after twenty-four hours, and 5.4 after forty-eight hours.

I would here recall that the process I described (*Chem. Zeit.*, 1893, xviii, 726), some years ago now, while being somewhat more complicated than the above, merits more confidence in judging the value of the glue.

This process consisted in measuring the consistency of the jelly formed by 100 grammes of glue and 300 grammes of water.

The question of determining whether a given glue is good or bad is one which is not easy to decide, unless we have to deal with a product that is altogether inferior. In the greater number of cases we simply endeavour to decide whether the glue is suitable for such-and-such a purpose.

As far as the adhesive power is concerned, I have shown, by numerous experiments, that from this special point of view, the glue from bones, which is of a decidedly inferior quality, is quite as good as that made from skin, which is of a superior quality. It is quite another matter in so far as the consistency of the jelly is concerned. The researches which I have carried out in this direction lead me to the conclusion that the jelly made from glues from skin is generally firmer than the jelly derived from glues from bone.

In the examination of a glue it must not be forgotten to notice the smell; this characteristic may give very useful indications as to the resistance of the product, and its tendency or not towards putrefaction; with regard to the above, skin glues are much better than those made from bone. Finally, the proportion of acid present in a glue is a matter of capital importance for certain purposes for which it is required. The method I have proposed (*Chem. Zeit.*, 1897, p. 691, and 1892, p. 1816) for the estimation of free and combined sulphurous acid, has once more enabled me to satisfy myself that glues from skin are superior to glues from bone. The determination of the water, ash, and fatty matters gives less important indications.

RICHARD KISSLING.

### CHEMISTRY IN PHOTOGRAPHY.

As the science of photography is based upon that of chemistry, it is remarkable how little chemistry is understood by professional photographers, let alone amateurs. Many amateurs do not know the various weights and measures, and I have known some quite unaware that the fluid measure contained fluid ounces, and, when they have required so many ounces of a solution, have weighed it by avoirdupois weight; had they even weighed it by apothecaries' weight, they would not have been quite so much out, but even then what a long and troublesome way against the measure.

Unfortunately, some of our English weights and measures are a little confusing, the legal English weight being the avoirdupois, with—

16 drachms.....	1 ounce or 437½ grains.
16 ounces.....	1 pound „ 7000 „

This is of little use in photographic solutions, emulsions, &c., owing to its being practically indivisible, and the generally used photographic weight is the apothecaries', with—

20 grains.....	1 scruple.
3 scruples.....	1 drachm or 60 grains.
8 drachms.....	1 ounce or 480 „
12 ounces.....	1 pound or 5760 „

This is a very useful weight, owing to its easy divisibility, the ounce being divisible by 2, 3, 4, 5, 6, 8, 10, 12, 15, 16, 20, 24, 30, 32, 40, 48, 60, 80, 96, 120, 160, 240, and of course by itself, and it is doubtful if any other weight is capable of being so much divided. In addition to this advantage is the fact that it exactly coincides with fluid measure, the table of which is—

60 minims.....	1 drachm.
8 drachms.....	1 ounce or 480 minims.
20 ounces.....	1 pint or 9600 „
160 ounces.....	1 gallon or 8 pints.

Chemicals are invariably bought by avoirdupois weight, while formulae are almost as invariably given in apothecaries'; consequently, if an ounce avoirdupois is taken, where an ounce apothecaries' is meant, there is a deficit of 42½ grains—rather a serious matter in working.

The metric system is very much advocated now, experimental chemists especially using it a great deal, but at present it is not very generally used or understood in England, although many efforts have been made to popularise it, the enormous expense necessary for the change being all against its general adoption. The multiples in this system are all in tens, and multiples thereof. The standard is the gramme, which was intended to be, and practically is, the weight of one cubic centimetre (c. c.) of distilled water at 4° C. or 39° F., its point of greatest density. The gramme is divided and multiplied by tens, the different weights being expressed by prefixes to the word gramme, as kilogramme, commonly called kilo=1000 grammes, or rather more than 2½ lbs., more correctly, 2.2046 lbs., the full table being—

10 milligrammes.....	1 centigramme.
10 centigrammes.....	1 decigramme.
10 decigrammes.....	1 gramme.
10 grammes.....	1 decagramme.
10 decagrammes.....	1 hectogramme.
10 hectogrammes.....	1 kilogramme.
10 kilogrammes.....	1 myriagramme.
10 myriagrammes.....	1 quintal.
10 quintals.....	1 tonne or millier.

The word gramme being dropped in the last two weights, the fluid measure coincides with this, the standard being the litre, and the full table being—

10 cubic centimetres.....	1 centilitre.
10 centilitres.....	1 décilitre.
10 décilitres.....	1 litre.
10 litres.....	1 décalitre.
10 décalitres.....	1 hectolitre.
10 hectolitres.....	1 kilolitre.
10 kilolitres.....	1 myrialitre.

The litre is slightly more than 35 fluid ounces, or 1½ pints.

Many of the chemical terms used in photography are Greek to the average photographer. He reads in the various technical works of halogens and haloid salts, but usually has no idea of what is meant by them. The halogens are the elements bromine, chlorine, and iodine; and the haloid salts the various metallic iodides, iodates, bromides, bromates, chlorides, and chlorates. The chemical symbols and equations given in the various formulae are quite foreign to many. They see it stated in an article that

by what is known as double decomposition or the changing of  $\text{AgNO}_3$  to  $\text{AgCl}$  and  $\text{NaCl}$  to  $\text{NaNO}_3$ , but they are little, if any, wiser for the information.

$\text{AgNO}_3$  is the chemical symbol for silver nitrate, which is formed by the action of  $\text{HNO}_3$  or nitric acid upon  $\text{Ag}$ , this latter being the chemical symbol for silver, the full name of which is Argentum.  $\text{NaCl}$  is the chemical symbol for sodium chloride or common salt.  $\text{Na}$  is the abbreviation of natrium, the chemical name for sodium, and  $\text{Cl}$  the abbreviation of chlorine.

One of the most necessary lessons to be learnt in chemistry is the atomic theory or law of combining proportions, discovered in the early part of the present century by the great John Dalton, which has done almost more than anything else to make chemistry a workable science. It is assumed in this theory that each element (in chemistry any substance which chemical knowledge has been unable to split up into two or more ingredients is called an element) is composed of atoms or indivisible particles, and that every element (of which, at the time of writing, there are sixty-five) has a distinct atomic or combining weight, so that, whenever any chemical compound is formed, the combination always takes place in those proportions or multiples thereof. Hydrogen, which is the lightest element known at present, is taken as the unit, and its atomic or combining weight is known as 1, the weights of the other elements varying up to thorium or thorium with an atomic weight variously given as 231.5 and 238, the atom of thorium thus being that much heavier than the atom of hydrogen. In the old books upon chemistry we find the atomic weight of hydrogen given as  $\frac{1}{2}$  and the weights of the other elements in multiples of this, but it will be readily seen that the present system is a much more convenient and workable one. Taking the aforementioned equation as an example.  $\text{AgNO}_3$  is a compound of silver, nitrogen, and oxygen in the proportion of 1 part silver, 1 part nitrogen, and 3 parts oxygen, as expressed by the symbols, the atomic weights of which are  $\text{Ag}$  108,  $\text{N}$  14,  $\text{O}$  16, giving  $\text{AgNO}_3$  the combined atomic weight of 170; and, presuming that we take 170 grains of  $\text{AgNO}_3$ , and analyse it, we should find 108 grains silver, 14 grains nitrogen, and 48 grains oxygen; with  $\text{NaCl}$  we find the atomic weight of  $\text{Na}$ , or sodium, is 23, and that of  $\text{Cl}$ , or chlorine, 35.5, giving the combined weight of  $\text{NaCl}$  as 58.5, so that, presuming we dissolve 170 grains of  $\text{AgNO}_3$  in half a fluid ounce of distilled water (distilled water must always be used where accuracy is required) and 58.5 grains of  $\text{NaCl}$  in another half fluid ounce of distilled water, and mix the solutions, we should get 143.5 grains of  $\text{AgCl}$  (silver chloride) precipitated, and 85 grains of  $\text{NaNO}_3$  (sodium nitrate) in solution, thus proving that the various elements have merely changed places, for we find, by adding 170 to 58.5, we get 228.5, which is also the sum total of 143.5 and 85. This wonderful discovery enables us to find the requisite quantities of two or more elements necessary to form a compound when once we know the atomic or combining weights of those elements; and this is easily obtained, for all good works upon chemistry give a table with the names, chemical symbols, and atomic weights of each element, and by this beautiful arrangement the chemical symbol of a compound also gives us the weight of the atom of that compound by simply adding together the combining weights of the elements contained in it, when the sum total is the atomic weight of that compound. This law is found to be invariably the same in any chemical change, where a complete chemical decomposition has taken place, but does not hold good in mixtures where no chemical change has taken place and where, no matter how finely powdered and carefully mixed, the elements may be present in any proportion.

The measures used in measuring fluids are the same which chemists use in dispensing drugs and prescriptions, and the usual sizes are 1 drachm, 1 or 2 ounces, and 10 ounces; the drachm measure is divided on the glass of which it is composed in 5 minim quantities up to 60 minims or 1 drachm; the ounce measure is generally divided into  $\frac{1}{2}$  drachm, drachm  $\frac{1}{2}$ , drachms 2, 3, and so on up to 8 drachms or 1 ounce; the 10-ounce measure is divided into  $\frac{1}{2}$  and whole ounces up to 10 ounces; the figures are also engraved upon the glass, each 10 minims being

figured in the drachm measure; 1, 2, 4, 6, 8 drachms in the ounce, and each separate ounce in the 10-ounce measure.

The study of chemistry will be found not only invaluable in photography, enabling amateurs especially to economise largely in making their own solutions instead of having to buy them ready-made, thus knowing the composition instead of working in the dark, but useful and instructive in many other walks of life, well repaying the trouble taken in learning. It is not to be expected that every photographer can obtain a complete knowledge of chemistry on account of the time and expense involved, but enough can be learned easily and cheaply, thus enabling the photographer to understand many of the changes which take place in photography, and preventing many errors; and, although a little knowledge is said to be a dangerous evil, it need not be so in this case if properly used.

C. T. SUTTON.

#### ART PRINCIPLES APPLIED TO PHOTOGRAPHY.

On Tuesday evening, April 25, Mr. Alexander Keighley, F.R.P.S. (President of the Bradford Photographic Society), lectured on the above subject at the Philosophical Hall, Park-row, Leeds, before the members of the Leeds Photographic Society. Mr. Godfrey Bingley said it was a very great pleasure to him to ask Mr. Keighley to give his lecture, as he was so well known, not only to the photographic world of Yorkshire but throughout the country.

Mr. Keighley, in introducing his subject, said a photograph is not necessarily a picture; a picture might be a photograph, but some knowledge and skill in art is requisite for the one, and might be conspicuous by its absence in the other. On two different days two men go out and photograph the same scene—a cottage, with a group of trees, but with quite different results; in the one case, one operator secured something more than a mere likeness of the place, investing it with a certain charm which will give delight and pleasure to those who have never seen the spot; the other looks commonplace, and would be interesting only to those who have some association with the place or know it well. In other words, one was a picture and the other a photograph. The reason was not far to seek. One used his camera as an artist, studied the composition of the picture to harmonise the whole effect, selected the most suitable light, as well as the proper time of day and the year, and, lastly, introduced a figure or figures in keeping with the scene and the sentiment of the subject; the other was a mere mechanical reproduction of the details of the scenery, and, if figures were introduced, they had come into the picture as it were by mere chance and had very little relation to the surrounding scenery, and would perhaps have been better left out altogether.

The difference was not the fault of the camera and lens, but one of knowledge of the rules of art or artistic perception, which might be largely intuition or as a result of long experience.

People were very ready to assume that photography was merely mechanical, and that pictures produced by its aid could not be artistic because the camera was merely a soulless implement. It depends on the hand that manipulates them and the brain behind the hand, and the photographer could use his camera pretty much in the same spirit as the artist. He did not want to claim too much for photography; although a man might not soar to the highest flights of genius, still he did think it might serve as a means of artistic expression.

To succeed in pictorial photography, the amateur must know how to handle his tools, be able to master exposure, development, and all the rest, and be able to produce a clean, sharp, technical negative, and also any desired effect by modification in chemical process and treatment. There should also be a training of the mind to see artistic pictures, largely attained by studying books on art and the works of great masters of art in the art galleries and in photographic exhibitions.

In speaking of art the term was very vague, and there must be something grasped and connecting it, and this he proposed to do as fully as possible by means of diagrams, drawings, &c.

One who wished to succeed in pictorial photography must have some knowledge of the rules of art, rules of composition, light and shade, fitness of details and accessories. As well might a man purchase a camera and brushes, and expect to go out in the country and obtain a painting which is to be a work of art, as a photographer who is entirely ignorant produce anything analogous. The object of composition is to present the subject in an agreeable manner, and to seek harmony and unity, to give pleasure to the eye without sacrificing any of nature's laws.

The first elementary rule is evidence of uniformity. The principal object ought never to be placed in the centre of a picture, and this applies very particularly where objects are of considerable height vertically or length laterally. A church with a tall spire should not be placed in the middle of the picture. Another thing to be avoided is the sameness of size and proportion. Straight lines running across the picture from side to side are another eyesore, and means should be found of breaking them up.

And now let us consider variety of composition. In making pictures two difficulties confront one at the outset. In the first place, we have to present on a plain surface, a subject which really occupies all various distances from foreground to extreme distance. A knowledge of com-

position gives the idea of separation of various planes, so that, when we look upon a picture, we lose the flat surface and feel we can look right into it, the foreground standing out and the distance far beyond. Composition helps us to convey the idea of space, and to do this we must not place objects perpendicularly over one another or horizontally level with one another; to do this carries out the straight lines that surround the picture generally or horizontally parallel to the bottom line of the picture.

Corresponding projections and horizontal similarities give no idea of distance in a picture except that effected by light and shade. Figures placed underneath principal objects did not give any idea of distance. The laws of composition were not mere arbitrary laws, but dependent on the free constitution of the mind itself, and the result of an experience of a lifetime to many who have given the whole story to the subject.

The next point in composition is the balance of lines, where there are a considerable number of lines running diagonally across the picture; some other lines placed at the reverse angle should be sought in order to compensate or give balance. Clouds very often come in useful as balancing lines. As to the balance of objects, in every picture there should be a principal object, and a secondary object to balance. These two should not be of equal importance, for, if this is so, the eye is distressed, and wanders about from one prominent object to the other. The principal object should form the key-note of the picture, and should be so prominent that the attention of the eye is at once taken to it; after this it may be drawn to the secondary one, and back again to the scenes on the principal object. In every picture there are also strong parts and corresponding weak parts. The weakest part is, of course, the centre of the picture, and no prominent object should be placed there, because it divides the picture into two and cuts it up into equal parts, and does not give the element of variety. A good way is to divide the picture into three parts, horizontal and vertical. Upon one of the parts one principal object may well be placed, and a balancing object of smaller importance on another part. This rule should not be adhered to in any mechanical way; circumstances alter cases, and it is very useful to have such a rule in one's mind, and to borrow from it only in combination with knowledge and discretion. If they studied the works of great artists, they would find that they had not been worked out in haphazard fashion. In making the general outline or scheme, they will follow some geometrical plan, although not made evident, as they remember that the principal object of art is to conceal art. Sometimes a diagonal line is made a sort of basis for the composition, at other times a pyramid, and others a circle.

A question often arose as between the photographer and the artist as to how much ought to be included in the picture. No law could be laid down. It is a subject which certainly calls for taste and discrimination of each individual brought to bear on each subject.

In conclusion, the lecturer said, in these days of photography made easy, it is necessary sometimes to remember, to obtain good pictures, forethought and careful consideration are necessary to the photographer, and that he, as well as the artist, should think his subject out for himself. His endeavour that evening had been to show that in photography there is ample scope for some of the highest powers by which man had been endowed by his great Creator.

The lecture was illustrated with a profusion of lantern views, and the lecturer frequently showed that the principles for which he was contending were exemplified in the works of the great masters. A cordial vote of thanks was accorded to Mr. Keighley.

#### ON THE SOLUBILITY OF ARGENTIC BROMIDE AND CHLORIDE IN SOLUTIONS OF SODIC THIOSULPHATE.

[American Chemical Journal.]

In the course of a series of experiments having a practical end as their chief aim, several determinations of the solubility of argentic halides in solutions of sodic thiosulphate were made. Since the data concerning this reaction are none too plentiful, it seems worth while to record briefly our incomplete work upon the subject.

The method of procedure was extremely simple. Solutions of sodic thiosulphate of known strength, made by dissolving weighed amounts of pure recrystallised material in water, were agitated for varying lengths of time in test tubes at a fixed temperature with an excess of argentic salt. The bromide had been freed from chloride by long-continued digestion with potassic bromide, and both argentic halides had been carefully washed, dried, and powdered. At the end of the allotted times, the agitator was stopped, the heavy precipitates were allowed to settle, and two portions were taken from each perfectly clear supernatant liquid by means of an accurate 5.00 c. c. pipette. The silver in these portions was now precipitated by sulphuretted hydrogen and collected on a Gooch crucible. Subsequently, the mixed precipitate and asbestos were treated with nitric acid in excess, the nitrous fumes were expelled, and the silver in the mixture was determined by Volhard's method.

The agitator, based upon the apparatus of Noyes (*Zeit. Phys. Chem.*, ix. p. 606; also Schröder, *Ibid.*, xl. p. 454), consisted simply of a rotating rod with a number of flat strips of brass soldered at right angles

to its axis. The rubber-stoppered test tubes were strapped to the brass strips by means of rubber bands, and the whole was immersed in a large Ostwald thermostat. A portion of the water of the thermostat was drawn off when it was desired to remove the solutions, so that the mouths of the test tubes might be uncovered, and, of course, the projecting mouths were carefully dried. A spring curtain-rod supporter, easily obtained in New England, formed a very convenient support for the rotating rod when soldered to the sides of the thermostat. The results with the second solution showed that four hours' agitation was enough to ensure saturation. No claim of great accuracy is made for the figures—indeed, the variations among them show their crudity—but they more than sufficed for our purpose, and are trustworthy enough to form an adequate basis for the remarks which follow.

It is thus evident that the quantity of argentic bromide increases more rapidly than the quantity of the thiosulphate. In this respect the behaviour of the bromide resembles that of the chloride, as observed by Stetefeldt (*The Lixivation of Silver Ores*, Craz and Gerlach, Freiberg, Saxony). Hence, simply judging from the solubility, one has a right to infer that the solubility concerns itself with the undissociated part of the sodic salt, for this is the part whose proportion increases when the concentration is increased.

The nature of the equilibrium is obviously so complex that the molecular ratios could not be expected to consist of simple whole numbers. Neither could the solubilities of the two halides be expected to conform to one another. In order to test this point, the solubility of argentic chloride in a solution of sodic thiosulphate containing 200 grammes of the crystallised salt to the litre was determined. Four parallel analyses of 5.00 c.c. of the solution saturated at 35° yielded respectively 0.344, 0.341, 0.342, and 0.341 gramme of silver, or, on the average, 0.454 gramme of argentic chloride per gramme of sodic thiosulphate. (Russell found 0.400 and 0.485 by two different methods; the first was evidently not saturated, the second supersaturated; Stetefeldt, pp. 19, 20.) Thus the molecular ratio was in this case 1:0.78 instead of 1:0.52 as in the case of the bromide. The difference is undoubtedly due to the different solubilities of the argentic halides in water, which, of course, must be factors in the complex equilibrium.

It is well known that from these solutions two well marked double salts (Herschel, *Edin. Phil. Journ.*, 1819, i. 26 and 398; also Lenz, *Liebig's Ann. Chem.*, 1841, xl. 94)—or, more probably, complex salts—may be obtained by crystallisation; but, of course, this fact does not show that these salts exist in the solution. As Barth (*Z. it. Phys. Chem.*, 1892, ix. 217) has pointed out, however, the inability of the solution to give the ordinary reactions of silver shows that a complex ion must be formed. More light might obviously be obtained from observations on the freezing and boiling points, as well as of electrolytic con-

ductiveness; indeed, Barth made an interesting beginning in this direction, and obtained evidence of the existence of a trivalent acid ion in the solution.

We proceeded in a somewhat different manner. Instead of studying the behaviour of the pure double salt, we observed the change in the freezing point caused by the addition of argentic bromide to solutions of sodic thiosulphate. In one trial, the addition of 0.8 gramme of argentic bromide to 26 grammes of a 0.54 mole solution\* of sodic thiosulphate raised its freezing point 0.08°, while in another trial the addition of 0.25 grammes of argentic bromide to 19 grammes of a 0.4 mole solution raised its freezing point 0.03°. Further additions in both cases produced no further rise, although much more argentic bromide dissolved; indeed, in the first case, a slight fall was subsequently observed.

According to modern hypothesis, such a rise in the freezing point can be produced only by the diminution of the number of active particles present. In the present case, the addition of another salt with different ions must, as usual, increase rather than diminish the dissociation of the sodic thiosulphate molecule; hence it could have diminished the number of active particles only by causing some of the undissociated material to condense into a complex structure, in which the silver is combined. Thus further evidence of the plausibility of Barth's conclusion as to the existence of a complex ion is afforded. The fact that, upon the further addition of argentic bromide, no further rise is produced, may be accounted for by the possible concomitant formation of another complex group, containing more silver—a reaction which might involve an increase in the number of active particles. The substances corresponding to these stages may well be the salts  $\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$  and  $2\text{Ag}_2\text{S}_2\text{O}_3 \cdot 2\text{Na}_2\text{S}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , which are actually known in the solid state. The double formula is assigned to the second salt simply in order to show at a glance that it contains more silver than the first. It is more likely that this second salt possesses a simpler formula, and that its partial formation, even in the beginning, prevents the rise in the freezing point from being as great as it would be if influenced by the formation of ions of the first salt alone.

In the course of the work the depression of the freezing point of water, caused by the addition of sodic thiosulphate, was also observed, as follows:—

Gramme molecule in litre.	Depression of freezing point.
0.202	0.855°
0.404	1.590°
0.535	1.980°

In brief, this paper contains data concerning the solubility of argentic bromide and chloride in solutions of sodic thiosulphate, cognate results upon the freezing points of the solutions, and a few remarks upon the probable nature of the complex substances formed. The subject is one of great interest, but the time at our disposal, as well as the inherent obscurity of the equilibria of concentrated mixed solutions, does not suffice to present a more complete view of the details of the reaction.

THEODORE WILLIAM RICHARDS,  
HENRY BURNELL FABER.

## Our Editorial Table.

### THE NEW TELLA CAMERA.

Manufactured by the Tella Camera Company, Limited, 110, Shaftesbury-avenue, W.C.

SINCE its introduction, in the summer of last year, the manufacturers of the Tella Camera have found opportunity of adding some improvements to that popular instrument, although it must be confessed there was very little scope available for such a purpose, the Tella, as it was first seen, creating a general impression that the *ne-plus-ultra* of hand-camera construction had been reached. The improvements that have been made attack detail rather than principle. Dimension and weight have been reduced, so that now the No. 3, or first-grade Tella, measures only 8 inches by  $6\frac{1}{2} \times 3\frac{1}{2}$ , and thus is comfortably carried in any position on the cycle, while the weight, charged with fifty films, is but three pounds six ounces—a veritable featherweight, considering what the Tella is set by its constructors to do in the way of photographic work. Of especial value is the fact that the camera is now given the motions of horizontal and vertical fronts.

There is so much concentrated ingenuity in the design and construction of the Tella changing principle that we here describe it in full, the diagram easily enabling the reader to follow the progress of the film from the focal plane to the storage chamber.

The camera is shown in the position in which a film is being changed, with the lens pointing downwards. *s* is the septum partly withdrawn; *r* is a fine wire rod, which helps to guide the septum and keeps it square. One is at the extreme left-hand side, whilst there is another on the right-hand side. The ends of these two rods are connected with a roller blind, *x*, which is automatically wound up, when out of use, by roller

\* That is, a solution containing 0.54×248.3 grammes of sodic thiosulphate in a litre. Such a solution would be called by some a 0.54 normal solution; but it seems to us that this nomenclature is an unfortunate one, and that the term "normal solution" should be reserved for the equivalent solutions so useful in volumetric analysis.

spring, xA. The chamber, w, is where the unexposed films are inserted. The septum, s, is shown being withdrawn with a film, v, held in its claw. z is a German-silver guiding spring. When the septum is being drawn outwards, it lifts the carrier, v, into the chamber, u, which is reserved for the reception of the films after exposure. It will be seen how the film is safely guided by the spring, z, from one chamber to another. As the edge of the film passes by the indicator, x, it changes the number, showing how many have been exposed. Should the septum be withdrawn without a film in it, it will be seen that there will be nothing to work the indicator. When the septum is right out, the film is left flat in the exposed chamber, and these films are held by springs to prevent them lying loosely in the compartment; also, when the septum is quite with-

drawn, the roller curtain is unwound off xA. When the front film is removed, there is nothing to support the small separator; it therefore falls upon the curtain, and either slides straight away into a small chamber for its reception, situated just below xA, or is carried into it by the blind as it is automatically wound by the roller spring, xA. The chamber that holds the separators is only open whilst the septum is withdrawn. At all other times it is closed, and it is not possible for them to become loose in the camera.

What takes place when the septum is being returned to its proper position is, that it first causes all the separators to be bent backwards or rearwardly, and all the unexposed films with them, except the front one. Between the front one and all the rest a wide space is left, and down this space the septum enters. Thus only one film is left absolutely flat in front of the septum, whilst all the others are protected behind it.

To further praise the Tella would be equivalent to painting the lily or gilding refined gold. Let us therefore only add that, besides the No. 3 (or de Luxe Tella), there is now a No. 2, and that the difference between the two instruments is shown by the appended extracts from their respective specifications.

#### No. 2.

*Lens.*— $5\frac{1}{2}$  Krugel, best quality rapid rectilinear.

*Aperture.*— $f/8$ , diaphragms  $f/6.5$ ,  $f/8$ ,  $f/11$ ,  $f/16$ ,  $f/22$ ,  $f/32$ .

*Focus.*—Fixed. Range ( $f/11$ ): Horizon to 24 feet. Tella magnifiers may be added for objects as near as six feet.

#### No. 3.

*Lens.*—5 inch Cooke Anastigmat.

*Aperture.*— $f/6.5$ , diaphragms  $f/6.5$ ,  $f/8$ ,  $f/11$ ,  $f/16$ ,  $f/22$ ,  $f/32$ .

*Focus.*—Camera itself is made to focus. An accurate scale is engraved, which permits focussing as close as two yards. No magnifiers required.

*Rising Fronts.*—Both horizontal and vertical. These can be used with the largest stops.

*Finders.*—Two, for vertical and horizontal pictures respectively. The Adams Patent Brilliant.

For the rest we may remind our readers that the Tella cameras take fifty cut films without backing pieces of any kind, the shutters working from  $\frac{1}{2}$  to  $\frac{1}{125}$  second, indicators registering the exact number of exposures made, a function performed by the film itself in its movement after exposure. Finally the cameras can be used either in the hand or on the stand. Than the Tella there is no more ingenious or beautiful machine on the photographic market, and, as time goes on, we expect its popularity to increase in the ratio of its age.

#### MERCK'S PYROGALLIC ACID.

E. Merck, 16, Jewry-street, E.C.

SOME years ago, when the "new developer" fever was nearing its maximum temperature, we heard a very well-known photographer at one of the meetings of a London photographic society make the remark that, if pyro were only then newly introduced, it would be hailed with great delight. Since that time several additions have been made to the list of our developing substances, but pyro still remains first favourite for negative work. In our opinion there will always be a constant and steady demand for pyrogallol, which experience shows, used with either soda or potash, gives the maximum amount of satisfaction as a developer. Hence special interest attaches to the introduction upon the English market of Merck's pyrogallol, which has long been popular on the Continent and in America. The sample which has been submitted for our inspection and trial could not qualitatively be excelled. It is a perfectly pure white flocculent production, readily dissolving into a clear

solution, and in actual use it has been found to produce negatives of ideal sparkle and density. We have never used a better pyro than Merck's, which, judging by the sample we have had in hand, should find great popularity among photographers.

#### THE "OPTIMUS" UNIVERSAL OUTFIT.

Manufactured by Perken, Son, & Rayment, Hatton-garden, E.C.

SURELY the "force of cheapness can no further go" when for seventy shillings such a well-made half-plate set of apparatus as that under notice may be obtained. To enumerate the articles comprising the set: the camera possesses leather bellows, rack-and-pinion focussing adjustment, and, as the diagram shows, a front and back swing, rising and falling front, mechanism for advancing the focussing screen quite near

to the front when a short-focus lens is in use, and square reversing frame. The lens is of rapid rectilinear form, with iris diaphragms and with roller-blind shutter fitted. The tripod is compact, strong, and rigid.

One book-form double dark slide is supplied. The camera is exceedingly light and well made, and the covering and defining powers of the lens are so good that it alone may be said to be worth the price charged for the entire set, which is exceedingly good value for the money.

#### THE "PRIMUS" HOLIDAY DEVELOPING OUTFIT.

W. Butcher & Son, Blackheath.

THE tourist photographer will find this little outfit of the greatest utility in places where facilities for changing and developing are not procurable. The whole of the articles pack in the dark-room lamp, which is only a few inches square. Here is a list of the things which, in Messrs. Butcher's words, will enable the photographer to make his bedroom a

dark room: Japanned tin dark-room lamp with sliding fronts (ruby and canary), and special power night light; three japanned tin dishes; rack and siphon tank for washing negatives; four-ounce measure; two india-rubber finger stalls; developing and fixing cartridges and dishes. The articles make a compact little set well worth the money charged (6s. for quarter-plate and 8s. for whole-plate), and the convenience of the outfit is so great that we are sure many travelling photographers will be glad to avail themselves of it.

## THE WATKINS ACTINOMETER.

R. Field &amp; Co., 142, Suffolk-street, Birmingham.

This little instrument is designed to give the same results as the Watkins Exposure Meters; but it is pointed out that, being without slide rules, it is not so convenient, and the exposure requires a little mental calculation. The method of its use is as follows: The exposure is always a fraction of the actinometer time (found by testing the light), and this fraction is

found once for all by dividing the diaphragm number, which is stamped on the back of the actinometer, by the plate speed, which is given on the speed card. Thus, Ilford ordinary with  $f/22$  always requires  $\frac{3}{5}$ , or  $\frac{1}{2}$  near enough of the actinometer time. It takes the same refill as the '99 watch and is provided with quarter tint.

This useful little device should be widely appreciated by those to whom a little trouble is of no account when correctness of exposure is at stake.

## THE THORNTON-PICKARD ALBUM OF PRIZE PICTURES.

Published by Dawbarn &amp; Ward, 6, Farringdon-avenue, E.C. Price 6d.

In this album we have half-tone reproductions of forty-four of the prize pictures in the Thornton Pickard Company's Competition which was held last autumn. The pictures are of special interest in that each one is an example of instantaneous photography, Thornton-Pickard shutters having been used with the whole of the 2000 photographs that were submitted for competition. A list of prize-winners and some notes on the competition are given in the album, which is extremely well got up, and is decidedly worth preservation as a memento of an instructive and interesting competition.

## News and Notes.

PHOTOGRAPHIC CLUB.—May 10. Members' Open Night.

The dates fixed for the Annual Exhibition of the Hackney Photographic Society are as follows: November 16, 17, and 18.

REMOVAL.—Mr. J. LIZARS, of Belfast, writes: "Kindly note that I have removed to new premises, 8, Wellington-place, Belfast."

MR. H. S. FOSTER, chemist, of 14, Honor Hill-road, Honor Oak, S.E., informs us that he has provided a dark room for the use of amateurs.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, May 9, at 12, Hanover-square, at eight p.m. "The Photography of Colour," by E. Sanger Shepherd.

THE Second Annual Dinner of the Association of Plate-manufacturers, &c., was held on Wednesday evening last, May 3, at the Restaurant Frascati, Oxford-street, Mr. Frank Bishop being the Chairman.

MISS CATHERINE WOLFE BRUCE has, through Professor J. K. Rees, given 10,000 dollars to Columbia University, to be used for the measurement and discussion of astronomical photographs. Miss Bruce's gifts to the department of astronomy amount to 22,100 dollars.

SOME members of the Agricultural Society are organizing a Postal Club for the encouragement of bird and animal photography. The co-operation of photographer naturalists is invited. Address Mr. Charles Louis Hett, Hon. Secretary *pro tem.*, Springfield, Brigg.

In applying for advertisements from the Eastman Kodak Company in Berlin, the Editor of a German paper called *Photo Humor* has recently found the inconvenience resulting from the use of blackmailing methods. Starting with the allegation that "humorous photographic papers such as his were those which really increased the number of amateur photographers," he proceeded to ask "how many less Kodaks the firm would sell in the course of the year if he published in his paper uncompromising remarks about the Eastman Kodak?" He concluded by remarking that "it would be to the interests of the firm to advertise with him," and he offered sixty per cent. discount off his regular advertisement scale. The matter came under the notice of the Public Prosecutor, who, at the hearing of the case, affirmed that the action of the Editor was against the German law, and he demanded that the defendant should be punished accordingly. The Court returned the verdict that the defendant attempted to obtain money by unlawful means and to damage the reputation of other people, and he must therefore go to jail for two weeks, without the option of a fine, and also pay costs.

EXPLOSION IN A PHOTOGRAPHER'S STUDIO.—At a studio in Gosport on Monday night preparations were being made to take a photograph by the flashlight, when the magnesium powder exploded, shattering the apartment. The photographer, Mr. Harvey, was burned about the face and hands, and it is feared that he has lost the use of one eye.

THE South London Photographic Society's Whitsuntide Excursion is to Farnham, Surrey. The Leader is Mr. F. Goddard, and the headquarters are at the Surrey Arms, East-street. Trains and fares will be announced at the meeting to be held on May 15, but no special concessions can be expected beyond week-end tickets, this being Bank Holiday time. Arrangements have been made for the hire of a brake, to take members for a day's drive, for 1*l.* 10*s.*, if sufficient guarantees are forthcoming to secure same previously.

DEVELOPMENT WITH METOL AFTER FIXING.—Messrs. Fuerst Brothers send us the latest formula for this purpose: Take  $\frac{1}{2}$  ounce to 1 ounce of the following solution:—Metol, 120 grains; sulphite of sodium,  $2\frac{1}{2}$  ounces; water, 20 ounces. After an hour or two, according to the exposure given (the plates should be strongly over-exposed and all traces of hypo removed) the positive image appears full of detail, visible by reflected light but scarcely perceptible by transparent light. At the end of two hours the image has grown sufficiently to be intensified with mercury.

McKELLEN, LIMITED.—The first shareholders' meeting of this Company was held at the works, Mill-street, Long Millgate, on Thursday, April 27, the Chairman of the Company (Alderman R. Lovett Reade) in the chair. The Chairman stated that the Company was registered in January. Steps were immediately taken to obtain larger premises than those occupied by the late firm, and after considerable difficulty the present premises, with over two thousand feet of floor space, all on one floor, were secured at a moderate rental, with option of lease. The removal of machines, shifting engine, and fitting up of the same were effected by the middle of February, and production was at once commenced. Steady progress has been made, the output of each month since the beginning being a distinct advance on the predecessor. Substantial orders are in the books, and the men are fully employed on them. A stamping press has been set up, by which not only will the cost of the mechanical portion of the instruments be reduced, but the production in adequate quantities will be greatly facilitated. He said the Directors had spared neither time nor thought in their desire to give the Company a good start, and, considering the short time the Company had been in existence, the result has been exceptionally satisfactory. He concluded by saying that no effort would be spared on the part of the Directors to make the Company a great success, and by inviting shareholders at any time to call and inspect the works. In reply to a question put by a shareholder, the Chairman said that the Company had given up their retail shop in Bull's Head-yard for two reasons: first, that their undivided attention might be given to the manufacturing department; and, second, because they wished to secure the favour of the local dealers. A hearty vote of thanks to the Chairman closed the proceedings.

## Patent News.

THE following applications for Patents were made between April 17 and April 22, 1899:—

CINEMATOGRAPHS.—No. 8173. "Improvements in Cinematographs." A. J. JONES and L. JONES & Co., LIMITED.

CINEMATOGRAPH.—No. 8245. "Improvements in Apparatus for Taking and Displaying Photographs of Moving Objects." Complete specification. M. BARR.

CAMERAS.—No. 8362. "Improvements in or relating to Photographic Cameras." G. W. BASE.

CAMERAS.—No. 8455. "Improvements in Photographic Cameras." P. M. GRIMSHAW.

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
5	Bradford Photo. Society .....	Fragments of Egyptian Discovery. Dr. Edwards.
8	Oxford Camera Club .....	Prize Slides.
9	Hackney .....	Concerning Exhibitions and Competitions. W. D. Welford.

13	Liverpool Amateur .....	Excursion: Rossett. Leader, H. Holt.

## LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 27.—Mr. S. Herbert Fry in the chair.

MR. T. E. FRESHWATER showed a few interesting objects bearing upon the paper read by Mr. T. Bolas before the Royal Photographic Society on the blowing of glass diaphragms thin to Newton's "very-black" stage. He passed round one of the identical bulbs blown by Mr. Bolas, showing Newton's rings in a marked manner. The extremely thin state of the glass which attended the production of the black stage (asserted to be something like a twelfth of the thickness of gold leaf) was so difficult to get that Mr. Bolas had not produced more than one or two at the meeting, and Mr. Freshwater was unable to exhibit one. They were so fragile, too, at that extreme thinness that they were liable to disrupt at any moment. The method of blowing the diaphragms was to take two pieces of glass tube, mount them side by side, but slightly separated, and connect to one end of each tube a branched rubber tube, the other end of which is inserted in the mouth. The two free ends, which should be flush one with the other, are then held in the blowpipe flame until the open ends fall in and close. By blowing through the rubber pipe at this stage the ends may be distended into bulbs, which, as they expand, come into contact one with the other, producing a single bulb, supported on two stems, and divided internally into two chambers by a diaphragm formed by the wall of glass where the two bulbs merged together. The bulb is still kept in a plastic state and the internal air pressure increased by degrees. It is obvious that the air pressure is the same on each side of the diaphragm, entailing no unwholesome strain, but on the walls of the bulb itself the effect is to still further expand, and in expanding to stretch the diaphragm until it becomes of such thinness that Newton's rings and interference phenomena set in. The black stage, which is that when light falling upon it is practically extinguished, only just precedes the bursting stage, hence the difficulty of their production.

In the discussion which followed Mr. Bolas's demonstration Mr. JOHN SKEAR referred to the beautiful films which Mr. F. H. Glew had succeeded in making in a solid other than glass. It had been surmised that in glass only had such extremes of thinness been possible, but it appeared that Mr. Glew had produced similar results in varnish. Mr. Freshwater brought up three or four of these interesting films. Like the glass films, they exhibited a considerable amount of colour due to interference, but differed in the fact that the thinnest portions were near the edges instead of the centre. These films are made by dropping a minute quantity of varnish of a particular kind upon some water contained in a dish or saucer. The varnish flies over the surface of the water in a thin layer, which may be picked up by a metal ring or a circular wooden box. When dry, it shows the phenomena described. Newton's rings may be manifested in a variety of ways. One of the commonest is to press a lens of very slight convexity upon a plane surface of glass. Mr. Freshwater passed round a device especially to show this experiment.

The application of flexible films to spectroscopic photography was demonstrated by an admirable photograph of the spectrum of iron by the electric arc in comparison with the solar spectrum, made by Sir Norman Lockyer. It was of considerable length, and the film was employed to permit the full use of a large-curved Rowland grating. The Kodak Company sent the photograph for exhibition.

## PHOTOGRAPHIC CLUB.

APRIL 26.—Mr J. W. Zaehnsdorf in the chair.

MR. E. DOCKREE read his Affiliation Lecture on

## DEFECTS AND THEIR REMEDIES,

classifying the former into two kinds: (1) defects due to carelessness, and (2) defects due to want of knowledge on the part of the worker. Particular attention was given to such defects as distortion of outline, imperfect focussing, those due to defective apparatus and its injudicious use, under-exposure and over-exposure in interiors and exteriors, irregular development, and the many ills which attend development, fog of all sorts, marks, halation, and reversal, and many more.

In the discussion which ensued Mr. J. R. GOTZ referred to the lens shade, the use of which had been mentioned. He preferred a metal framework attached to the front of the camera, upon which the focussing cloth could be arranged to give the right amount of shade. The idea he got from a Glasgow photographer.

MR. F. A. BRIDGE and other speakers spoke of the disadvantage such a device would be under in a high wind, and pinned faith to the ordinary metallic shade attached to the lens, as being more solid.

MR. E. W. FOXLE said that Ross wide-angle doublets were always fitted with an adjustable sky flap, which could be placed at any angle, in any position with regard to the lens and light.

MR. J. NEBIT showed some examples of a method of correcting convergence of perpendiculars in a photograph. The idea was to copy the defective picture in the camera, the correction being secured by tilting the picture to an angle to be decided upon.

The prints were certainly improved by the copying, but the question arose that the height of the perpendiculars was shortened, and the image altered consequently in perspective and in size. It was represented that the plate also should be tilted if one wished to avoid the dwarfing or stunting of the vertical lines.

A cordial vote of thanks was passed to Mr. Dockree for his personal attendance, a course which much enhances the value of a lecture compared with its reading by another.

**Croydon Camera Club**—An audience of not less than forty assembled on Wednesday, April 26, to witness Mr. JAMES PACKHAM, F.R.P.S., demonstrate

## HOW OZOTYPE IS WORKED,

and to hear his explanations of this somewhat remarkable new printing process. In the course of a few introductory remarks the PRESIDENT congratulated the Club on its being the first photographic society to follow up Mr.

Manly's announcement at the Royal Photographic Society by the demonstration to be given by Mr. Packham of this probably most useful process. For this they were deeply indebted to Mr. Packham for his enterprise and ability. The lecture and demonstration proved to fully warrant the interest evinced by the large attendance. The lecturer began by giving an illuminative description of the process, from which it would appear that the picture or print is produced by light forming an allotropic oxygen image. How this is seized on by the manganous salt with which the paper is coated, how the acid bath acts on the carbon tissue, and why hydroquinone is used were clearly explained. Without following Mr. Packham through all his manipulations we may say that the *modus operandi* is much as follows: The paper is brushed over with potassium bichromate and a manganous salt in solution; it is dried, printed, washed, and squeezed on to carbon tissue, which is then developed in warm water, as is the usual carbon print. The printed image is a visible one, so that one can judge by ocular inspection how the picture is progressing and how much additional light action is called for, which in an ordinary carbon print is not possible. Mr. Packham handed round prints in various stages, and also developed some which he had prepared from negatives of his own. A large number of prints made by Mr. Thomas Manly were also shown, several of them being characterised by much beauty of effect and in other respects illustrative of what might be done by the new process. For the loaning of the above and for otherwise facilitating the preparation of the demonstration the audience's thanks were tendered to Mr. Manly. The discussion was participated in by Messrs. MACLEAN, ROGERS, BEN. EDWARDS, KOUGH, S. H. WHITTEN, HAWKINS, and WATSON. Asked by the President as to the percentage of failures Mr. Packham had met with, he answered "he had met with none." Mr. Rogers had, however, found blemishes arise through dark spots, some as large as sixpenny pieces, which had shown themselves on his prints. These were inexplicable, except on the theory that there was some chemical impurity in the paper used which set up an oxidising action; but in one case the paper was single transfer paper used in ordinary carbon work, which is presumably free from casual impurity.

**North Middlesex Photographic Society.**—April 24, Mr. R. B. LODGE gave a lecture on,

## WILD-BIRD PHOTOGRAPHY,

illustrated by lantern Slides. All the species shown were native to this country, but a few are extinct now or nearly so; these latter were photographed abroad, chiefly in Andalusia in Spain and in the marshes of Holland. Nearly all the examples were taken with a tele-photo lens on a heavy camera. The difficulties he had to contend against were very great. To get within proper distance, sometimes two or three yards, it was necessary to envelop himself in a green-baize sack, with a cover for the camera of the same material, and to lie for hours in a suitable spot with the camera focussed on the nest, and to wait until the birds came back or had got accustomed to the stranger near them. The birds themselves perched on branches or sitting on the nest, the nest themselves with the young birds waiting open-mouthed for worms and grubs were all shown. In the case of aquatic birds standing for hours in waders with water up to the middle is often necessary. The failures in this branch of photography were very great. Wind was a great source of trouble, also the birds moving and various other causes.

**Leeds Camera Club.**—April 27.—Annual Meeting, Mr. R. Bourke (the Vice-President) taking the chair.—The retiring officers and Committee of the Club, in their annual report, congratulated the members on a most successful year. The increase in the membership during the whole year has been constant, about a hundred having been added to the roll since the reconstruction in April 1898. The Club was invited to join the Yorkshire Union during the past year, but by a unanimous vote it was decided not to do so, as the Club could gain no advantage from participating in such a scheme. Regarding the future, the Committee desired to point out that in the syllabus arranged for the coming session there will be found the names of the leading workers of Great Britain, and that probably no photographic society has such a fine list of lecturers. It is proposed in the coming session to make special arrangements for the encouragement of the attendance of ladies, and the Committee reminded members that ladies are eligible for election as members. The report was unanimously adopted, and the election of the new Committee and officers took place. On the counting of the votes, Mr. R. Bourke (the Vice-President) declared Mr. W. J. Warren re-elected as President; Messrs. C. L. Rogers, Major Norwood, A. C. Homburg, and J. Charters Birch were elected Vice-Presidents; Messrs. Skilbeck, Barnes, Elif, Emmott, Morfett, Powell, and Paley were elected for the Committee; and the other officers were chosen as follows:—Mr. F. Rust, Hon. Treasurer; Mr. John H. Gash, Hon. Secretary; and Mr. R. Bourke, Lanternist, with Mr. C. Grayson as his assistant.

## FORTHCOMING EXHIBITION.

1899.

May 5-13 ..... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

**LIQUID HYDROGEN.**—At the Annual Meeting of the members of the Royal Institution, held on May 1, Professor Dewar made a brief reference to the recent scientific work of the Royal Institution, and announced that, having obtained liquid hydrogen in considerable quantity, he had directly determined its temperature and other physical constants, finding its boiling point to be much lower than was previously supposed, namely, 20° above the zero of absolute temperature, and attaining by exhaustion a temperature of only 15° absolute. Pending the discovery in quantity of some yet lighter gas, there was no means in sight of bridging this gap and reaching the zero point. He also took occasion to warn the public against absurd exaggerations as to the properties of liquid air, which, originating in America, found their way into popular magazines in this country.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* We do not undertake responsibility for the opinions expressed by our correspondents.

### KEEPING QUALITIES OF PLATES.

To the Editors.

GENTLEMEN,—As a contrast to the experience of your correspondent in the issue of April 14, it may interest your readers to know that, of several dozens of plates taken out to India, in January 1898, for the total eclipse of the sun, not one was found unsatisfactory on account of any deterioration. Of course, the actual plates exposed during the eclipse were developed on the spot, but the remaining plates which had not been used were brought back here, without any such special care as was taken when they went out. That is now fifteen months ago, yet I used several of these remaining plates a few days ago (size 16×6 inches), and found them still in perfect condition. The plates were Lumière, Series A, Extra Rapid, and Edwards's Snap shot Isochromatic (Anti-halo). So far as I could judge, the rapidity of the plates was scarcely different to that of the fresh article.—I am, yours, &c.,

CHARLES P. BUTLER.

Royal College of Science, South Kensington, London, S.W.,

April 22, 1899.

### RE ANOTHER SECRET PROCESS.

To the Editors.

GENTLEMEN,—With reference to the above, we would beg to say that recently a man called upon us with specimens of bas-relief portraiture, and offered us the sole agency for the district. When we asked him for further particulars, he stated that it was a very simple process, and he would teach us for a fee of one guinea, upon which we declined with thanks. He gave no name, but we gathered that he came from Brighton.—We are, yours, &c.,

A. WILDMAN & Co.

The Maybury Studio, Maybury-road, Woking, April 28, 1899.

### PHOTOGRAPHY AT FUNERALS.

To the Editors.

GENTLEMEN,—Having read several comments in your excellent paper relative to photography and funerals, perhaps it might interest your readers to know that there are, in this, as in most other cases, two sides to the question, for it was only two or three months ago that I received a commission to be at the church lych gate in order to photograph a funeral, with choir and clergy. This was from one of the chief mourners. The proceeding to my mind was so very painful that I declined the offer, and I think most photographers would have done the same.—I am, yours, &c.,

E. H. DUNMORE.

Downton, April 28, 1899.

### SHUTTER-SPEED TESTING MACHINE AT THE CAMERA CLUB.

To the Editors.

GENTLEMEN,—Probably, owing to some misunderstanding, your report of the above practically states that the speed-testing machine shown at the above Club was the invention of Dr Lindsay Johnson. This, we feel sure, the gentleman named would not for one moment suggest. Whilst at our works he saw and much admired our excellent system of testing the speeds of shutter, and requested us to make him a couple of the instruments. This we have done, and are pleased to find that, with his well-known generosity, he has presented one of them to the Royal Photographic Society, and the other to the Camera Club.

We shall at all times be pleased to supply similar machines to others requiring them, yours, &c.,

ADAMS & Co.

26, Charing Cross-road, W.C.

### A SOCIETY FOR PHOTOGRAPHIC PRINTERS.

To the Editors.

GENTLEMEN,—I don't know that I can do better than thank Mr. Randall for his remarks upon my letter, as one can easily see that he has the whole thing in a "nutshell." He (Mr. Randall) first points out "that our trade is a mere infant when compared with carpentry, plumbing, and bricklaying, and consequently the distinctions between its various members have not yet reached so definite and fixed a boundary

as those between the members of the building trade." Exactly; but is that any reason at all why "our members" should not make a start? Why cannot "our members" (the photographic printers) form their section? I don't think for one minute Mr. Randall wishes to throw "cold water" on a scheme which probably is the only way, under present conditions, to unionise photographic printers. I shall await with interest for your correspondent's reply.

Again, he says, "The want of knowledge concerning trade unionism displayed by the average assistant is well put by Mr. Willatt, viz., 'I must be free to take what wage I please,' assuming wrongly that trade unionism destroys such a liberty." Here Mr. Randall points out that what trade unionism does do is to prevent the assistant accepting twenty shillings if twenty-five shillings be the union rate of wage. Quite right, so far, but still the assistant will say, "I must be free to take what wage I please." There is competition and fighting for berths, and the assistant can't stand out of a berth because he cannot get twenty-five shillings; he says again, "Half a loaf is better than none." Now, if Mr. Randall would show some better means of meeting the case than a photographic printers' union, I should be extremely glad. Dear sirs, I honestly think under present circumstances that it is an impossibility to get photographic printers to join the National Amalgamated Union; but let them have a union of their own, and then amalgamation will in due course follow. I also feel assured of the fact that the sooner photographic printers join hands, and agree as to what a printer's fair wage is, the better, and the sooner they have some means of a knowledge of certain rules which seem to predominate with certain firms the better also. "Fewer unions and more union." Yes—but let us not forget that it is the little tributaries (little rivulets) that form the great current bounding on towards the everlasting sea.—I am, yours, &c.,

F. G. WILLATT.

101a, Fulham Palace-road, Hammersmith, W.

### NORWAY IN JUNE.

To the Editors.

GENTLEMEN,—I expect to spend about three weeks in Norway in June, and wondered if you or any of your readers could give me a hint or two in reference to the photographic work there.—I am, yours, &c.,

NORWAY.

[Will some reader oblige our correspondent with a few hints?—Eds.]

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 2A, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

W. Lander, 1, Regent's-parade, Shanklin, I.W.—Two photographs of Royal Museum, Carrisbrook, I.W.

A. M. Riddle, 4, Strathaven-terrace, Oban.—Photograph of "Free Church Convention" group, photographed at Oban, Argyllshire, N.B., on April 12, 1899.

L. WEST.—No, it is not the case.

T. ROBEAR.—The address is Avenue-road, Shepherd's Bush.

O. K.—We should not consider such services worth more than 1*l.* or 1*l.* 5*s.* a week at the outside.

H. J. HILLHOUSE.—Mercury is occasionally recommended to be added, but we believe the Company supply a special solution for the purpose, which perhaps it would be best for you to procure.

COCKLED CELLULOID FILM.—T. DEACON. The trouble was caused by your drying the films in spirit. Celluloid is partially, or wholly soluble in strong spirit, and should not therefore be used for celluloid films.

ALBUMEN AND GELATINE.—You are under a misapprehension; the two can be mixed in any proportion, but the mixture must not be heated beyond the coagulation point of the albumen, otherwise it will coagulate, and thus separate as a flocculent mass.

T. W. BARBER.—We doubt if the tone desired is producible in the way described. Alpha paper and the new gaslight development papers, such as Velox, Dekko, &c., might, however, answer your purpose, the colour being directly produced by exposure and development.

LENS QUERY.—F. BEALE. If the lens be a symmetrical one, it matters not which is used as a single one; but, whichever is used, the convex side should be next the ground glass, and the stop next the concave side. All rectilinear lenses, however, are not symmetrical, though the majority of the modern ones are.

**MARKINGS ON PRINTS.**—H. AYLWARD writes: "Will you kindly inform me what the marks on enclosed prints can be? It happens on a few in a batch only. Every care is taken in all stages of the process."—The marks are due to particles of foreign matter coming in contact with the prints while they are wet. What the foreign matter may be, we cannot say. Particles of pyrogallie acid, or other reducing agents, would produce similar spots.

**STUDIO.**—R. MINNA. The only advantage of a studio with a north light is that it is easy to work and requires less skill on the part of the photographer; but a skilful photographer will get equally as good pictures in a studio with any other aspect. The results depend upon the artist rather than the aspect of the studio, therefore do not attribute the whole of the success of —'s pictures to the fact that his studio is lighted from the north; to do so would be a fallacy.

**MOUNTING PRINTS WITHOUT COCKLING.**—C. C. WRIGHT says: "I have to mount some photographs in an album the leaves of which are of thin card."—There is considerable difficulty in mounting prints under these conditions without their cockling. The best way is to take the leaves out of the album, and then mount, and roll the prints in the usual way. Then rebind the album. If this cannot be done, then use the mountant given on p. 1061 of the ALMANAC.

**COPYRIGHT.**—F. T. BLACKBURN says: "I have taken a photograph of the Salterton Town Band, and the Bandmaster wrote me, giving me permission, on behalf of his men, to copyright same, and your publishers kindly undertook registration for me. I was not paid for photographing them, but have since sold copies to the members of the band. I have every reason to believe that it has been infringed. Have I a clear case?"—In reply: Yes, you have an absolutely clear case, and can impose your own terms.

**OPPOSITION.**—B. & Co. Unless you have an agreement to the contrary, there is no reason why the late operator and manager of the branch should not open a business a few doors off, and so "do your business an injury." The fact that he was five years in your employ, and knew all the customers, goes for nothing. He can also say on his circulars and on his shop front so many years with you, provided your name is not used in such a way as to imply that the business is yours, or is connected with yours.

**GROTESQUE PORTRAITS.**—GROTESQUE says: "Could you please tell me how the grotesque portraits are produced, such as a very large head (a true portrait) on a small body, such as Highlander dancing, or man riding donkey, &c.; also where I can get materials from for their production?"—There are different ways of producing such portraits, such as double printing, placing sketches before the figure when the portrait is taken, &c. If we mistake not, Fallowfield's supply the necessary appliances. Write them.

**NEW USE FOR OLD PYRO BOTTLES.**—A PHOTOGRAPHER'S DAUGHTER writes: "Would you kindly inform me if there would be anything deleterious to health if I were to use the empty blue bottles and corks, used by Schering's for storing pyrogallie acid, for bottling fruit, if they were thoroughly washed and cleaned? They are a most convenient size for the purpose, but I thought I had better inquire before using them."—In reply: Wash the bottles and corks copiously with hot water and you need have no fear of any ill effects.

**CRYSTALLISATION OF DEVELOPING SOLUTION.**—METOL says: "Will you tell me the cause of the following developer crystallising when cold:—Metol, 40 grammes; sulphite of soda, 120 grammes; hydroquinone, 45 grammes; water, 8 ounces. I dissolved metol in the 8-ounce hot water, then thoroughly dissolved the sulphite, then added the hydroquinone?"—If the solution were made in the order mentioned, there should be no crystallisation when cold. We have never had it behave so ourselves. Possibly there was some error in the order of mixing.

**RESIDUES.**—S. R. writes, complaining that he did not receive nearly the amount he expected for some residues he sent to a well-known London house to be reduced. That is very likely, because, possibly, he expected too much. Residues, nowadays, contain but very little silver compared with what they used to do when highly salted and strongly sensitised albumen paper was in vogue. Modern gelatine papers contain but little silver to be recovered, while the baryta coating adds very materially to the weight of the ashes. Further, the value of the silver, when recovered, is but half that of what it at one time was.

**STUDIO GLAZING, &c.**—J. H. C. says: "I should be glad if you would kindly answer the following questions:—1. I have reasons for wishing to glaze the side light of my studio with ground or fluted glass; should I be at any disadvantage in doing so? I have about 3 x 20 feet of plain glass for top light. Is there any special glass you could recommend (other than plain) for the side light? 2. What is the best means of preventing or removing the objectionable pyro stains from the finger nails?"—1. There would be no disadvantage. 2. On p. 972 of the ALMANAC are receipts for removing pyro stains from the fingers. But the stains are more difficult of removal from the nails, unless some abrading material, such as pumice powder, be used in addition.

**FERROTYPES.**—R. PRYOR says: "I am a photographer and a regular reader of your paper. I intend opening a tent on a 'public amusement ground' for ferrotypes. Have got Fallowfield's lists, but I don't know how to work the plates. Can you give me the following information, which will greatly oblige? What are the developing constituents most suitable? How are the pictures reversed? Do you know of any book on the subject? I am going in for dry-plate ferrotypes."—The most suitable developer is that supplied specially for the plates. If you did not receive the formula with the plates, write for it. For the moment we do not remember the one issued for these plates. Ferrotypes are all reversed, and remain so. Fallowfield publishes a work on ferrotypes.

**CERAMIC PHOTOGRAPHY.** A. JOHNSTONE.—There are no patents that will interfere with your working either the powder or the substitution methods of ceramic photography.

**WET-PLATE WORK.**—F. B. says: "I should be greatly obliged if you can inform me if there is much opening for a good wet-collodion worker, as I have been wondering lately if this particular branch of photography is worth following up. I am at present working as a wet-collodion lantern-slide maker, but am desirous of following the process further. Is there much opportunity of getting into process work? If you can tell me through your valuable JOURNAL, I shall be greatly obliged."—The working of the wet-collodion process is now chiefly confined to negatives for process blocks and making enlarged negatives for carbon printing. If you are a skilful worker, we think you would find employment; but, of course, the process is but comparatively little worked now.

**CYANIDE FUMES.**—S. WOODS asks: "Is there any way of doing away with the injurious fumes from cyanide of potassium when used for fixing wet-collodion negatives or transparencies? Are they injurious in a well-ventilated dark room?"—We know many who have [worked with the cyanide for years, both in photography and in electro-plating, without their suffering any ill effect. With some, however, it at times causes a headache and nausea, but rarely if the room is well ventilated. Often there are far more fumes evolved than there need be, owing to the cyanide solution being poured off the plate into the sink while it contains some remains of the acid developer. The acid then causes an evolution of cyanide fumes. Better develop over one sink and fix over another, so as to keep the two solutions apart. Then there will be little of the "injurious" fumes given off.

**AN ATTIC AS STUDIO.**—C. GORHAM says: "I have had an attic over my office made up into a sort of studio for my own private purposes, having two semi-skylights, and I enclose herein two proofs of my first attempt—one a rough proof off negative before retouching, and the other after retouching. Now, I want to ask you to be kind enough to tell me whether the light arrangement is about right, for I had no screens, shading fans, &c.; all I had was a grey background of my own painting. I am aware the heat in this subject caused the shade; could this have been obviated by light reflections?"—The portrait is flat owing to its being lighted entirely from the front. A much better effect would be got by working across the studio, so that the sitter be illumined by a side light. The shadows can be easily softened by reflectors. Fairly good portraits can be obtained in the room.

**SPOTS ON PRINTS.**—THE MAJOR says: "I should be much obliged if you could kindly give me your opinion regarding these small brown specks on enclosed print. I cannot understand the cause, as I am very particular to adhere to instructions regarding the toning, &c., of the paper, and do what I will I cannot get a perfect batch. Sometimes I have only one or two prints, and at others about a quarter of the batch spoil like enclosed. It is only quite recently this has happened. Do you think it is through the water containing rust, or is it in the chemicals? To me it seems to be rust if scraped with a knife. I should be much obliged to receive your opinion on the matter, as it is causing me much extra trouble, and is very annoying."—If the water contains particles of iron rust, the spots are fully accounted for. We see no reason for suspecting the chemicals. Try the effect of using water from another source.

**SPOTS ON PRINTS.**—SPOTTED PRINT says: "We are sending you some prints which, you will notice, are to an extent covered with small black spots. We have taken every precaution in the washing, toning, and fixing processes. We find that these spots always appear on the prints during the first washing. We have put the cause down to particles of iron in the water. Could you suggest any way of filtering the water as it comes from the tap? Do you know of any reliable filter on the market, and where it could be obtained? We have tried muslin and cotton-wool tied on the tap, but have not found it answer. We may mention that we have used two different brands of paper with the same result."—In reply: Particles of iron in the water would cause similar spots, and we should think that cotton-wool in muslin or flannel would keep them back if properly secured over the tap. Maignen's Filtré Rapide and the Birkenfeld filters are both good. They may be procured through any ironmonger.

**AN ETCHING QUESTION.**—J. BENTLEY says: "In your issue of January 30, 1890, there appears an article on Plate Etching, and towards the bottom of first column appears: 'Having some recollection of the facility with which fine lines could be drawn by the needle point upon glass which had received a coating of silver, so we silvered a glass, &c., and impressed image by means analogous to the Daguerreotype.' Now, I wish to know how this image is got by that process, of which I am ignorant as regards working details, and whether the same is applicable to copper for engraving or etching purposes, as a man in our district does work for engravers on copper, and the surface of plate is white and the image is black? Could you enlighten me on this, I should deem it a favour. I thank you for answer re Studio, in which I am doing good work, though facing west. I have covered the glass by V. Blanchard's method, which appeared in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1897 or 1898, with tissue paper soaked in linseed oil, and it makes a splendid ground glass, for which I may say I am thankful, and it may be of use to others."—In reply: To describe the working details of the Daguerreotype process would take up several pages of the JOURNAL. We must therefore refer our correspondent to some of the earlier works on photography, Hunt's, for example. The Daguerreotype plate is a copper plate, silvered on its surface. We cannot say how the plates referred to are produced, but, if one was sent for us to see, we could probably tell how it was done.

## EX CATHEDRA.

THE Royal Commission for the Paris Exposition of 1900 has entered into communication with the Camera Club and the Royal Photographic Society with a view of delegating to a Joint Committee of these bodies the task of making a representative collection of British pictorial work to be sent to Paris for display at next year's great Exhibition. It is to be hoped that such care will be exercised in the appointment of the Joint Committee as will ensure that the photographs to be forwarded to Paris will be drawn from all available sources in Great Britain where good or representative photographic work may be found. The proceedings of the Joint Committee will be followed with a great deal of interest, and the method of selection adopted will, no doubt, be narrowly scrutinised. If any attempt be made by a certain small knot of persons to impose their own peculiar views as regards the selection of the photographs, a keen resistance to such a proceeding may be anticipated.

THE Second Annual Dinner of the Association of Plate and Paper-manufacturers, which was held on Wednesday in last week at the Restaurant Frascati, was made the occasion of the presence, under the genial chairmanship of Mr. Frank Blahop, of a fully representative gathering of the members of the Association. The company with the guests, which included the whole of the press and some other gentlemen, numbered about forty, and the vice-chair was occupied by Mr. John Howson. The festivity was a thoroughly enjoyable and harmonious one, and on these grounds alone it is permissible to hope that it will become an annual institution with the members of the Association.

\* \* \*

THE following firms were represented at the dinner: Britannia Works Company, Marion & Co., Kodak Limited, Wellington & Ward, Morgan & Kidd, Imperial Dry Plate Company, R. W. Thomas & Co., Paget Prize Plate Company, Mawson & Swan, Cadett & Neall, Elliott & Son, and others. The Secretary of the Association was also present. There were very few speeches, the principal one being made by Mr. Howson in response to the toast of the Association. In giving a brief history of the Association during the two years of its existence, Mr. Howson dismissed the term "ring" which had been applied to it as an erroneous one, pointing out that the regulation of the retail prices of sensitive plates and papers could not properly merit an appellation usually held to have a different meaning. It was gathered from Mr. Howson's remarks that the utmost success had attended the Association's objects, with which dealers and others were in thorough sympathy. The toast list also included "the Chairman," "the Vice-Chairman," and "the Guests," and a notable evening in the annals of British photographic trade and manufacture terminated with the singing of "Auld lang syne."

\* \* \*

THE interest excited in the election of Judges for next autumn's Royal Photographic Society's Exhibition appears to be exceedingly keen. A considerable number of members have agreed upon a voting list, which is in circulation, and in all probability the result will be an indication of the wishes of the large majority of members in this very important respect. Ballot papers should be sent in by the 31st inst.

DURING their stay at the Villa Liserb, Cimiez, Her Majesty the Queen and the Royal Princesses gave Mr. A. L. Henderson twelve sittings for their photographs, the resulting negatives being highly approved. By command of the Queen, Mr. Henderson also photographed the ceremony of the opening of the Victoria Bridge. On Wednesday, May 3, he was summoned to the Austrian Consulate and presented on behalf of the Emperor with a very handsome diamond and ruby breast-pin in recognition of his skill in photographing the unveiling of a monument to the late Empress Elizabeth. We congratulate Mr. Henderson on the honours of which he was made the recipient.

\* \* \*

LORD CRAWFORD presided at the Annual Dinner of the Camera Club, which was held in the large room of the Club-house, Charing Cross-road, on Thursday evening, May 4. There was an attendance of about ninety members and friends, amongst whom were Professor Unwin, Mr. Lyonel Clark, Mr. George Davison, Mr. Payne Jennings, Mr. E. J. Humphery, the Rev. C. J. Moncrieff Smyth, Mr. Seyton Scott, Mr. E. Sanger Shepherd, Mr. Horace Willmer, Mr. Reginald Craigie, Mr. J. Wallace Godfrey (Hon. Sec.), Mr. W. Asbury Greene, Mr. Thomas Bedding, Mr. H. Snowden Ward, Mr. Percy Lund, Mr. R. Child Bayley, Mr. William Croke (President-elect Photographs Convention of the United Kingdom), Mr. H. Walter Barnett, Mr. R. Freer Austin, Colonel Marshall, Major Levy, Colonel Saunders, Mr. William Nicholl, the Rev. Father White, and many other prominent members of the Club.

\* \* \*

THE after-dinner entertainment was extremely amusing, being provided by some gifted "Savages." The toast list was short, merely including "The Queen and Prince of Wales," "The Club," "The Press," and "The Chairman." Following Lord Crawford's lead, some of the speakers indulged in the hope that the growth in prosperity of the Club would one day necessitate the acquisition of much larger premises than it at present occupies. It also appeared, from the remarks that were made by the various speakers, that the efforts of the Executive to cater for the intellectual and other needs of the members were highly appreciated by the latter, and an evening of great enjoyment terminated with the general hope that a prosperous future awaited the Camera Club.

\* \* \*

LAST week we mentioned that the British Pictorial Section of the Florence International Photographic Exhibition had met with great appreciation at the hands of the visitors. The sincerity of this appreciation is evidenced by the fact that on the opening day ten per cent. of the contributed British pictures were sold, including productions by Messrs. Ralph Robinson, Thomas Manley, W. S. Aston, E. E. Barron, Henry E. Davis, Charles Job, Karl Greger, W. J. Warren, H. V. Hyde, E. Calland, and J. Craig Annan. Further sales have since taken place. The photographers whose names we have mentioned should be proud of the knowledge that their works have gone into the possession of Florentine art lovers.

\* \* \*

MR. ALFRED STIEGLITZ, of New York, kindly sends us an invitation which time and distance oblige us regretfully to pass over. It is to inspect a one-man show of his photographs that are on view at the New York Camera Club until the 15th

instant. From the tastefully produced catalogue to which Mr. Joseph T. Keiley contributes a sympathetic eulogy of pictorial photography and the prominent part played in its progress by Mr. Stieglitz during the last twelve years, we gather that the Exhibition consists of nearly ninety photographs. It includes most, if not all, the many very beautiful studies which Mr. Stieglitz has from time to time contributed to the English exhibitions. To each entry in the catalogue brief details of the printing process employed by Mr. Stieglitz and descriptive notes upon the history and characteristics of his photographs are added. Mr. Stieglitz, we perceive, owes his first medal to Dr. Emerson. From long familiarity with the style and qualities of Mr. Stieglitz's work we are confident that visitors to his exhibition will be charmed by the sure but tender touch the author puts in all his productions, and we only regret that we have not the chance of seeing the collection.

## COLOUR FACTS AND FALLACIES.

### I.

FOR the third time in less than three months we have found it desirable to advert to the theme which is indicated by the heading of this article. The fascination that clings to the subject of colour photography is not greater than the interest which attaches to those who make that branch of work the object of special investigation. The assailants of one of the greatest problems of our time command an amount of popular attention which is denied to the majority of ordinary men, from whom they have separated themselves in the search after the philosopher's stone of photography; and it cannot be said that the distinctive public recognition which has been vouchsafed to the latest gentleman in whose colour-photography labours the world has been invited to interest itself falls short of the requirements of the case. Mr. J. W. Bennetto—the gentleman in question—could not have been made more of by some of the newspapers if he had been a billiard champion, a successful jockey, or a victorious pugilist. It may be worth while examining how far the greatness that has been thrust upon Mr. Bennetto is really deserved, and upon what evidence his claim to have discovered the philosopher's stone above alluded to should be allowed to rely.

For reasons that will subsequently appear we are not called upon to notice the defence of the Bennetto three-colour process which was printed in a photographic publication last week. The source and object of those observations absolve us from any obligation to pay the least attention to them. Moreover, we can dismiss as absurd the charge, which was made, of "injustice" towards Mr. Bennetto's process. If three years ago that gentleman had contented himself by claiming to have worked out simply a development of the three-colour process, the criticisms we have felt it our duty to pass on his words and work would not have been called for, and his process to-day would have needed no apology or defence at the hands of sympathetic persons whose common sense is obscured by their touching anxiety for justice.

The uncompromising attitude of scepticism which THE BRITISH JOURNAL OF PHOTOGRAPHY has always taken up towards Mr. Bennetto's claims to have discovered photography in natural colours—his own words were: "I claim to have solved the problem"—was dictated by a reasonable doubt as to whether Mr. Bennetto had really made any material original discovery in colour photography, and we want no other or stronger justi-

fication for that attitude than the admission which has been made that Mr. Bennetto's much-vaunted solution of the problem is merely a development of the three-colour process, the publication of which some months ago created throughout the photographic world what the editor of our contemporary, *The Optician*, so well described as "a feeling of painful surprise."

We are aware that Mr. Bennetto and his doings are favourite topics with the readers of this JOURNAL; and we are confident of the sympathy of thousands in our efforts and determination to keep him off a pedestal on which he has no right to stand. It is, of course, needless to add that we have no hidden motive in this course, although it might appear that the vigour which we have endeavoured to impart into our references to Mr. Bennetto's proceedings laid us open to the sinister charge of personal feeling. Such, however, is not the case.

But, if we have been sceptical of the tenability or admissibility of Mr. Bennetto's claims to have "gone one better" than Ives, Lippmann, and Joly in colour photography, we have been at considerable pains to assist Mr. Bennetto in securing opportunities for taking the opinions of representative bodies of photographers on those claims. Out of the mass of Bennetto literature we have preserved, in view of possible eventualities, we take the following letter, which Mr. Bennetto addressed to us personally on August 18, 1896, in acknowledgment of a suggestion which we made to him: "In reply to your suggestion that I should send a picture to that excellent Society, the Royal Photographic, I fear I should not be able to do so until after my exhibition here; but I should be quite willing to come up and exhibit, say, thirty or more slides of various subjects before the members of the Royal Society if desired to do so, although I have not the honour of being a member, and on that occasion I would give you every opportunity of seeing many others as well (stereoscopic)," &c.

We suppose Mr. Bennetto's exhibition (at Newquay) has still to be held, for he has not yet appeared at the Royal, and we have not had the opportunity of seeing the slides, stereoscopic or monocular. But, determined to exert all our power to induce Mr. Bennetto to submit his work for the inspection and criticism of the photographic public, we expressly prepared another opportunity for him to do so. The arrangements for the papers and demonstrations at the Great Yarmouth meeting of the Photographic Convention of the United Kingdom were partly in our hands, and we wrote to Mr. Bennetto, asking him to send some specimens of his work for exhibition. It will be remembered that the notorious Chasagne process was demonstrated at Great Yarmouth.

Mr. Bennetto replied, on May 20, 1897: "If it is possible, I will send an example or examples of my photographs in colours to the Convention; but at the present time I am not able to speak very positively upon this point, and for the following reason: I am at the present time working out something else in connexion with photography of a very important character, and, as I am anxious to complete this as soon as possible (for important reasons), I have been compelled to put my new method of colour photography aside, and I am not in a position to say if I shall have any specimens of my new method ready in time; but, if I have, I shall be very pleased to send them. I do not intend to exhibit any more examples by my old method, as I have made a great improvement, the working details of which, however, are not quite complete, for the reasons given."

The specimens were not shown at the Convention, and thus

for a second time we were foiled in the attempt to obtain for those interested the sight of a few examples by one of apparently several processes of colour photography which Mr. Bennetto seems to have worked out only to abandon. At any rate, it appears plain, on Mr. Bennetto's own showing, that between August, 1896, and May, 1897, he had given up an "old" method and invented a "new" one.

Whether it was this "new" method or a newer one which Mr. Bennetto, when we had the pleasure of meeting him in London during the month of February, 1898, voluntarily promised to demonstrate to us in the coming spring, adding that we should be the very first to witness the demonstration, we cannot say, for, although considerably more than a year has elapsed, Mr. Bennetto has failed to keep his promise.

We must ask the forgiveness of the reader for imparting into an article of this nature so many details of a personal kind; but we have felt it a duty which we owed ourselves to make it plain that, while we have never faltered in our attitude of scepticism towards Mr. Bennetto's claims, we sought every opportunity of giving him the chance of destroying our scepticism by advancing some evidence in support of his pretensions. But, even if he had redeemed his promise, and allowed us to witness his method of working the "development of the three-colour process," the result has shown that the secret was not a particularly valuable one.

So much for the purely personal aspect of the matter. The ridiculous suggestion that we have been deliberately hasty and unjust towards a process which has turned out to be something altogether different from what it was claimed to be having been disposed of, we conclude with the promise to give further extracts from our stock of Bennetto literature next week.

---

**Spring and Spring Photography.**—One need not be reminded that spring is now with us, or that spring effects in photography can only at be had this season of the year. But it may be well to remind some of our readers, as we have done in some previous years, that certain pictures are available now that are not to be had at any other time. For example, churches, abbeys, ruins, &c., are frequently so surrounded by trees that they cannot be seen, at a photographable distance, when the foliage is on. To take such views when the trees are absolutely bare, the naked boughs and twigs convey a dismal wintry and unpleasant effect; but, if the same subject be taken when the leaves are just budding forth, the effect is entirely different, though the main object may be as fully depicted as when the trees are perfectly bare of foliage, and therefore make far more pleasing pictures. Hence our reminder that such pictures can only be obtained just now.

---

**Methylated Spirit.**—Perhaps it scarcely need be stated that the so-called methylated spirit is ordinary alcohol, to which has been added some foreign substance to give it such an unpleasant odour and nauseating taste as to render it impossible to use as a potable liquid. For many years methylic alcohol, otherwise known as pyroligneous spirit or wood naphtha, was used for the purpose, hence the term "methylated." It was, however, found that, nauseous to the taste as this mixture was, it was yet used freely as an intoxicant, and wood spirit was discarded for a mineral oil which, on account of its precipitation upon the addition of water, is objectionable for photographic use. It is true that the Inland Revenue, under certain precautions, allow the purchase of the old kind of duty-free spirit, but only in large quantities; hence many less photographically objectionable materials have been proposed as substitutes in this "denaturalising" process. The most recent suggestion is the employment of the oils produced in the manufacture of acetone

Dr. Lang, a Swiss chemist, having patented their use for the purpose. In the course of an exhaustive article upon the practicability of employing this new agent, it has been shown, first, that the oil would answer; but, secondly, that it is not produced in sufficient quantity to prevent a great rise in price if its use were to become general.

**Royal Portraits.**—The paragraphist has been at work again, and, as is not unusual, has been "drawing the long bow," we suspect. A paragraph has been going the round that ten million photographs of the Queen and the Prince and Princess of Wales are produced annually and find a ready sale. We have little doubt that those who possess negatives of these Royal personages wish the facts were as alleged. That there is a large sale for portraits of our Royal Family, both at home and abroad, is a pleasing fact; but, when we are told that it amounts to ten millions annually, one cannot help being a little sceptical on the subject. Possibly, however, the paragraphist may not be at fault; it may be that the compositor had some ciphers in his "case" that he wanted to get rid of.

**Addition to Kew Gardens.**—Last week the Queen's Cottage at Kew was thrown open to the public, or rather the grounds in which it is situated. The little cottage makes a capital subject for photography, and some excellent pictures may be had in its grounds, many of which are admirably adapted for the stereoscope, so are many other views in Kew Gardens. More especially are the interiors of the conservatories and palm-houses adapted for stereoscopic photography, and few things make more pleasing pictures for the stereoscope than such subjects. But it is essential to success that the plates be well backed to avoid halation. Permission to photograph in the grounds and houses must be obtained, but that is readily done by a written application to the Director of the Gardens. The permit, when obtained, also enables its holder to have access to the grounds and conservatories with his camera before they are opened to the general public, which is a great convenience to the photographer. Just now, when the foliage is young, the gardens are especially suited for photography.

**Another Beauty Spot Threatened.**—One by one the beauty spots of Great Britain seem to be doomed. The Falls of Foyer is a case in point. This, not long ago, was acknowledged to be the noblest waterfall in these islands; but now it is robbed of its principal charm because a manufacturing company required a cheap source of water power, chiefly for aluminium works. Now the beautiful Lakes of Killarney are to come under the hammer, or at least a large portion of the district. On the authority of the solicitors for the vendors, what is actually to be put up for sale includes "the Middle Lake of Killarney, a moiety of the Devil's Punchbowl, a moiety of the Mangerton Mountain, two-thirds of the Purple Mountain, the entire of Torc and Innies Mountains, Dinnish and Brickeen Islands, Muckross Abbey, Torc Waterfall, O'Sullivan's Cascade, the Colleen Bawn Rocks, Lord Brandon's Cottage," &c. In all, between 13,000 and 14,000 acres of one of the most beautiful parts of Ireland, so well known to tourists and photographers, are for sale, and, we believe, without restriction as to what use the waterfalls may be applied. Such is the course of events.

**Test for Wood in Paper.**—The peculiar effect of wood as a constituent of paper has frequently been alluded to in these columns, one of the earliest examples having been an instance of alleged "fading" in carbon prints, a "fading" which consisted merely in a yellowing of the whites, the name being given, we presume, by reason of a mistaken analogy to the degradation of the whites in albumenised prints—a common accompaniment of true fading in such photographs. It is obvious, therefore, that a ready means of discovering whether or no a paper is made of virtually pure cellulose—linen rags, &c.—or has an admixture of wood pulp in its texture, is worthy of record. The number of such means has recently been added to by Signor Arnaldo Piutti, who finds that ortho-bromo-

phenitidine hydrochloride imparts to wood a deep yellow tint, while cellulose, the ordinary textile fibres, chitin or chitin, are not acted upon. The reagent is capable even of estimating within a reasonable degree of accuracy the quantity of wood present, as the yellow tint is still produced when all the extractive matter has been removed from the pulp.

**The Metric and the English Systems.**—Anent our reference, a fortnight ago, to the fact that metric weights and measures are not, or need not be, more costly than corresponding ones on our present system, a correspondent writes that fluid measures are supplied, or may be obtained to order, graduated on both systems, i.e., fluid ounces and drachms on the one side and c. c. on the other, so that either scale can be used at will; thus one measure will serve a dual purpose. We are aware of the fact also that the dual graduated measures cost no more than the ordinary, except for the secondary graduations. Further, we have stamped our metric weights with punches with their equivalents in English grains. In this way one set of weights serves for both systems. Any one possessed of a set of number punches, which may be had for a trifle, can stamp his metric weights for himself without trouble. There is no reason why weights, so marked, and which would entail but a trifling additional cost, should not be supplied commercially.

**Another Local Picture Exhibition.**—On Saturday last Mr. G. A. Storey, one of the nominated Judges for the next Royal Photographic Society's Exhibition, opened the Tenth Annual Loan Picture Exhibition at the Borough Polytechnic Institute. In declaring the Exhibition open, Mr. Storey said that these exhibitions gave much pleasure to many thousands of hard workers, who found in art a pure pleasure and a recreation from toil; also that, in the long run, they might benefit artists themselves, for they would show what the public at large most appreciated, and not only merely what satisfied people at the West-end, adding that art should become a real and true friend of the people. This is a practical view of art—what the general public most appreciate. We surmise that the majority of the general public do not much appreciate certain modern "art" photographs, i.e., those of the Salonistic school.

**Royal Society's Soirée.**—At this annual function, which was held on the 3rd instant, there was a most interesting display from Sir W. Crookes in connexion with photography and phosphorescence. It has long been known that certain substances exposed to the molecular bombardment in a Crookes' tube become strongly phosphorescent, and Sir William has been investigating their production, and of late years that portion in the ultra-violet region. These rays are mostly absorbed by vitreous media; hence, to enable them to be examined by photographic means, prisms and lenses of quartz which are transparent to these rays have been used, and at the *Soirée* a set of apparatus, including the necessary apparatus, was shown—a spectrograph with two quartz prisms and condensers. The sensitive surface to receive the rays must be curved and set at an angle to enable proper definition of the lines to be given. To this end celluloid is used as the film support instead of glass, and is curved to a segment with a radius of 190 mm. and set to an angle of 40°. Among the series of photographs taken was one with a set of lines near those of yttrium and supposed to belong to still another new element not hitherto separated. This has been named "Victorium."

#### THE RESEARCHES OF EDMOND BECQUEREL ON DIRECT HELIOCHROMY.

EDMOND BECQUEREL'S researches on the production of colour on chlorinised silver plates began in 1838, and his papers on the subject, to which he gave references in the course of some observations\* on Lippmann's first communication of his method to the French Academy, are as follows:—

\* *Comptes Rendus*, t. xvi. p. 181, and t. xvii. p. 483, 1848; *Ibid.*,

\* *Comptes Rendus*, 1891.

Regnault's Report, t. xxviii. p. 200, 1849; *Annales de Chimie et de Physique*, 3<sup>e</sup> Série, t. xxii. p. 451, 1848; *Ibid.*, t. xiv. 447, and t. xlii. p. 31; Edmond Becquerel, "La Lumière, ses Causes et ses Effets," t. ii. ("Effets"), pp. 209-232.

In 1857, Becquerel read a paper on the subject before the French Photographic Society,\* of which the following is a full translation:—

"I have been asked several times, to give the whole of my researches upon the reproduction of colours under the chemical action of light. I do it with pleasure, although these experiences date back some years and may not be immediately applicable to photography; but, as the substance which has the remarkable property of receiving coloured impressions from light is susceptible of curious physical modifications, I shall give some details, so that those who are interested in the study of the chemical action of light can reproduce easily the different effects which I have obtained.

"There are a great number of substances sensitive to the chemical action of light; some show a partial or complete decomposition, such are certain compounds of silver, of lead, of mercury, of gold, of platinum, &c.; others require the presence of substances which can react upon them, such is chlorine in presence of hydrogen, chromic acid in presence of organic matters, gusiacum in presence of oxygen, &c., but usually, when decomposition takes place, wholly or partially, or when a chemical reaction is shown, the colour of the sensitive substance changes, though often only giving a monochromatic shading, which depends upon the nature of the new compound formed.

"If you take, for example, the iodide of silver, which loses its yellowish colour to darken under the action of light, the new colour which it shows is independent of the refrangibility of the actinic rays. To study better the effect produced, it is necessary to use a solar spectrum, that is to say, of the image formed by the dispersion of the solar rays by means of a prism; if this image is received upon a surface covered with iodide of silver, this last begins to colour in the violet part of the spectrum, and even beyond the violet, then in the blue, that is to say, in the most refrangible part of the visible spectrum; but the tint of this substance, darkened more and more in proportion to the action of the light, is not in accord with the tints of the actinic parts of the spectrum.

"In working with other bodies it will be found that chemical action is shown in the different parts of the spectrum, and one is brought to a similar conclusion.

"One can sum up the preceding remarks by saying that each substance is sensitive between the different limits of refrangibility, and that, reaction being once set up, there is usually only one tint produced, which does not correspond with the colouring of the actinic rays.

"However, amongst all the substances tried there is one which seems to give several tints under the action of the spectrum; it is the chloride of silver. When it is prepared under the usual conditions, it takes a violet tint under the action of diffused light, then afterwards it deepens to brown. If it is exposed to the action of the luminous spectrum, it begins to show colour in the ultra-violet and violet part. Then, if the action is of some duration, and there is diffused light in the dark room, it takes, in the red part of the spectrum, a brick-red tint, as Seebeck observed for the first time.

"Herschell† and Hunt,‡ who have studied the action of light upon different sensitive papers, have also observed that the chloride of silver gave this reddish tint in the red part of the spectrum. It is known, on the other hand, that the chloride of silver coloured violet, if heated, takes a reddish tint exactly like that which is observed in the red part of the spectrum.

"One might suppose that this last effect was due to the action of heat in any case, as the chloride of silver, when it begins to colour, is slightly violet; that it begins to take colour in the most refrangible part of the spectrum, and that, on the other side, it takes a brick-red tint in the least refrangible part, was a singular coincidence to see the two extreme ends of the photogenic impressions of the spectrum turn, one to violet in the violet, the other to red in the prismatic red.

"I began in 1838 and 1839 to study this subject. I had thought that the effect of colouration produced in the visible part of the spectrum was due to a calorific action; but since then I understand that it is not so.

\* "Exposé des Procédés au moyen desquels on peut obtenir la production des Couleurs sous l'action de la Lumière. Fait à la Société Française de Photographie, le 18 Décembre, 1857, par M. Edmond Becquerel, Professeur de Physique au Conservatoire Impérial des Arts et Métiers" (*Bulletin de la Société Française de Photographie*, t. iii. 12 pages). For a copy of this paper I am indebted to M. Henri Becquerel of the Paris Académie des Sciences.

† *Bibliothèque Universelle de Genève*, 1839, tome xxiii. p. 185.

‡ *Ibid.*, tome xxvi. p. 407.

"I have made experiments to determine the conditions under which these results are very clearly obtained. If the chloride of silver is not obtained by double precipitation on the surface of paper, but in a test glass, and deposited upon a surface, such as glass, porcelain, &c., if this chloride has not been exposed previously to the light, as soon as the solar spectrum is projected upon its surface, it only begins to show in the ultra-violet part, and only a light violet tint is obtained, which darkens more and more; on the other hand, there is nothing produced in the visible part of the prismatic image; but, if perfectly pure chloride is used, without excess of nitrate, and this chloride has been exposed beforehand, the effect is very appreciable in the violet, the colour darkens more and more, and is like that which would be produced by diffused light; but, in the red part, a light rosy tint is obtained, and there is no effect well manifested in the yellow and green part, where, nevertheless, a faint discolouration is observed.

"If the chloride is obtained on the surface of a paper, dipped successively in salt water, then in a bath of nitrate of silver, and that there should be an excess of nitrate, the effect is not the same. In this case, where the sheet of paper has not been exposed beforehand to the light, and no chemical action is seen but in the ultra-violet part, as where the paper has been exposed to the rays, and it becomes sensitive even in the sensitive part of the spectrum from the blue to the red, there is then a continuing action, and the effects of colouration are weak, if they are even observable.

"I thought from this to prepare the chloride of silver directly by attacking a layer of silver by either gaseous chlorine or arising from the decomposition of chlorides. I worked then by exposing a silver-black to the action of gaseous chlorine; the layer became greyish-white, and, on throwing the solar spectrum upon its surface, no clear phenomenon was observed, only a greyish tint showed itself in the violet, and denoted a chemical reaction. I then attacked the layer of silver by chlorine given off from chlorine water, or, better still, by dipping it in chlorine water itself. The layer, having remained plunged in the water for some minutes, had covered itself with a deposit having a grey-white tint, and the actions of light were very different. After having projected the luminous spectrum upon its surface during some minutes, upon drawing out the layer and examining it by daylight, I perceived a kind of souvenir of the spectrum fixed upon the layer, of which the parts corresponded exactly with the luminous parts of the solar spectrum; the place where the red ray had fallen was pale red, the yellow was yellow, the blue blue, &c. Upon placing again the layer in the same position, and letting the action of the spectrum continue for some time, the effects disappeared, and, in the end, a grey tint remained, which extended over all the parts upon which the spectrum fell. I saw then that it was not only a simple coincidence of tint which had given to the chloride of silver exposed beforehand the red colour of one side of the spectrum and violet of the other, but that in this case the unchanged white chloride was mixed most likely with sub-chloride, that is to say, of a chloride having an equivalent of chlorine, less than the white chloride, and that this last substance gave rise to the tints observed.

"I substituted then for chlorine water solutions of chlorides and hypochlorites, capable of yielding chlorine to a silver layer, and I obtained, as with the first solution, surfaces capable of reproducing the image of the spectrum with its colours.

"That which has succeeded the best, the composition of which I published in 1848, at the time of the publication of my first work,\* is a solution containing bichloride of copper. The following preparation is very easy to obtain. Take the ordinary sulphate of copper and chloride of sodium; put these two salts in excess in a test glass with a certain quantity of water; the solution produces a double reaction and forms bichloride of copper. Mix a part of this liquid with a part of a saturated solution of sea salt and six parts of water; then plunge a plate of silver, or plated with silver, in this liquid; it takes quickly a violet tint, due to the presence of a light layer of chloride of silver, and it becomes sensitive to the action of the spectrum, of which it reproduces the principal colourings. The layers of silver employed should be of great purity, because this treatment brings out the slightest traces of foreign matter which are found on the surface.

"I ought to say, however, that this manner of preparation, though simple, does not allow the increase at will of the sensitive layer; therefore I have quite given it up in my other experiments,† to substitute for it a manner of preparation which allows the layer obtained to give results otherwise remarkable, and to have any thickness wished.

\* Paper presented to the Académie des Sciences de l'Institut, February 7, 1848, and published in the *Annales de Chimie et de Physique*, Série III. tome xxii. p. 451.

† *Annales de Chimie et de Physique*, Série III. tome xxv. (1849) p. 447, and tome xlii. p. 81.

"This formula consists in bringing, little by little, by the action of electricity, to the surface of the layers of plate chlorine in the nascent state, which attacks the silver, and gives sensitive layers.

"To make this preparation, take a plated plate well polished and cover the reverse side with an alcohol varnish, in order that there should be only the silver surface to conduct electricity, and upon which the chlorine can act.

"This plate is fastened with hooks of copper to the positive conductor of a voltaic pile of one or two elements. A thread, or a plate of platinum, is attached to the negative pole, and the plate of silver, with that of platinum, is plunged into a mixture of 8 parts of water and 1 of hydrochloric acid by volume. The chemical action of the electric current gives hydrogen upon the platinum, and chlorine upon the silver, at the positive pole. This last is then attacked, and, in fact, it colours itself a violet-grey; then the tint deepens, and, if the action continues during some minutes, the plate becomes black, as if covered with smoke. When once the plate is thus prepared, it need only be polished with cotton or leather to clear away the kind of veil which covers it, and it can be used to reproduce immediately coloured impressions under the action of light. This process of preparation of chloride is the best which can be used to obtain the reproduction of the images of the spectrum with all its tints, and, under certain conditions, the images of the dark room.

PHILLIP E. B. JOURDAIN.

(To be continued.)

#### AMMONIUM PERSULPHATE—ITS PROPERTIES AND USES.

We have received a letter from Professor Namias, pointing out that his valuable paper, "Ammonium Persulphate—Its Properties and Uses," which appeared in our last two issues, originally appeared in his journal, *Il Progresso Fotografico*, and he also says that, through an error, the sentence on p. 231, line 14 from bottom, column 2, "'Namias now remarks that the existence of a large excess of persulphate must only result in the solution of the chloride' is unintelligible, and that the word we have italicised should be 'silver salt.'"

MM. Auguste and Louis Lumière recently read a note before the Société Française de Photographie in which they combat this statement of Professor Namias and say, that when they pointed out the curious property which ammonium persulphate possesses of reducing negatives by dissolving the densest parts of the image in preference to the half-tones, that is to say, in acting at the bottom of the film rather than at the surface, they had propounded a theory which has been the subject of some contradictions.

They have admitted in effect that ammonium persulphate dissolves the silver image and gives rise to the formation of a double sulphate of ammonia and silver according to the equation—

They supposed that this double sulphate was in proportion to its formation diffused through the film of gelatine into the solution containing the excess of persulphate, and that the latter could, like hydrogen peroxide, play in this case the part of a reducer, in the presence of water, simply by the disengagement of oxygen according to the following equation:—

In this way any exterior solvent action of the persulphate on the silver was prevented by the tendency towards an inverse action, which gave rise to the precipitation of silver on the surface of the image. They explained in this way why the density of the image was reduced from below to the surface of the image, and not in the inverse direction as is usual.

Professor Namias contends that their hypothesis is not correct, because ammonium persulphate does not reduce silver nitrate when a small quantity of soluble silver salt is added to an excess of ammonium persulphate, which is the case when a negative is placed in a solution of this reagent. The reduction not taking place, except in the presence of an excess of a soluble salt of silver, M. Namias does not admit the possibility of a deposition of silver on the negative.

In order to confirm their original hypothesis, they have prepared directly the double sulphate of silver and ammonium by dissolving to saturation precipitated silver in five per cent. solution of the persulphate.

They have proved that this double salt can, in the presence of a reducer such as pyrogallol acid or hydroquinone, deposit metallic silver on a negative, that is to say, it can act like a physical intensifier, without

any silver being directly reduced in the solution, which remains clear in the cold sufficiently long for it to deposit its silver on a negative placed in it.

It may be admitted, therefore, that the silver is precipitated from the soluble salt on the negative without this action actually taking place in the solution itself; consequently, this remark is no contradiction to their first hypothesis.

#### PRACTICAL NOTES ON SOME IRON PRINTING PROCESSES.

##### PART I.—WHITE ON BLUE GROUND.

##### *Ferro-prussiate, Negative Cyanotype, Blue Printing.*

THIS process, probably, was discovered by Sir J. Herschel about 1840–42, and named by him Cyanotype, from *κυανός* (cyanos), or some dark-blue substance known to the ancients, probably *lapis lazuli*. Essentially the process consists in (a) coating paper with a mixture of ammonio-citrate of iron and ferrocyanide of potassium; (b) exposure to light, producing insoluble Prussian blue (i.e., Turnbull's blue,  $\text{Fe}_3\text{O}_4$ ); (c) development by washing away with water the soluble portions, resulting in a positive print (from an ordinary negative), showing a picture in blue on a white ground. The resulting image is unaffected by hot or cold water, and is practically permanent.

*The Paper.*—The character of the result varies according to the kind of paper used. The best paper for this process is that made from rags, and containing very little, if any, wood pulp. It should not be strongly sized or highly glazed, and when looked through should appear of an even woven texture, without clear or opaque spots. Plain Rives paper is recommended, as also are the better kinds of smooth drawing papers. A two per cent. solution of arrowroot in boiling water is suggested as a good strength for sizing a paper not previously sized.

*Sensitising Mixtures.*—A large number of mixtures have been used with varying results.

##### HERSCHEL'S FORMULA.

A.	
1. Ammonio-citrate of iron .....	20 parts.
Water .....	100 "
B.	
Potassium ferriocyanide .....	16 parts.
Water .....	100 "

If distilled water is used, the above solutions will keep good a long time. In preparing B, the crystals should be first rinsed quickly with cold water, and then thrown on to blotting-paper, to be dried before being weighed. (N.B.—This salt is poisonous.) If this precaution of removing from the ruby-red ferriocyanide the surface yellow powder of ferrocyanide be neglected, the purity of the whites in the resulting print will be impaired. The sensitising mixture consists of equal parts of A and B, mixed as required, and filtered before use. The mixture will keep for a while if stored in an opaque bottle, but for evenness of results freshly made mixtures are recommended.

*Coating the Paper.*—In order to render the sheet more manageable, it may be quickly dipped in cold water, then laid between clean blotting-paper until it is just limp, but not wet. It is now pinned down on a flat board or stiff card, and the sensitising mixture applied with a Blanchard's brush, or small, clean sponge partly stuffed into the neck of a bottle, or by a soft hair varnish brush, or, preferably, by a cotton-wool brush. Or the paper may be floated on to the mixture for about three minutes. Care must be taken to coat the paper as quickly and as evenly as possible, i.e., by moving the brush first one way the length of the sheet, and then again at right angles to the first strokes.

*Drying.*—Next it is highly important that the paper be dried as quickly as possible, so as to keep the coating mixture on the surface. Drying should take place in the dark. In summer, some place where there is a strong draught may serve; in winter, each sheet may be held before a fire for a few moments.

##### Other Sensitising Formula:—

A.	
2. Ammonio-citrate of iron .....	1 part.
Water .....	4 parts.
B.	
Potassium ferriocyanide .....	1 part.
Water .....	4 parts.

For sensitising, take equal parts. (It may be observed that this is equivalent to saying "120 grains per ounce.")

A.	
3. Ammonio-citrate of iron .....	150 parts.
Water .....	500 "
B.	
Potassium ferriocyanide .....	80 parts.
Water .....	400 "
Mix and add potassium bichromate, 1 part.	

This addition is said to improve the keeping qualities of the mixture, and also of the paper when coated. The addition of 5 to 10 parts of pure alcohol has been suggested for the same purpose.

A.	
4. Ammonio-citrate of iron.....	9 parts.
Water .....	30 "
B.	
Potassium ferricyanide .....	80 parts.
Ammonia (880) .....	7 "
Oxalic acid (saturated solution) .....	60 "
Water .....	300 "

Mix in equal proportions. This, again, is more sensitive than the original formula.

5. To prevent the watery solution sinking into the paper and yielding a dead, flat, "sunk-in" look, various additions have been suggested, e.g., gum, &c.:-

A.	
Gum arabic .....	1 part.
Ammonio-citrate of iron .....	5 parts.
Water .....	20 "

B.	
Potassium ferricyanide .....	3 parts.
Water .....	20 "

Mix in equal proportions to use.

6. The following formula is said to yield a paper that keeps well and prints quickly:-

A.	
Boracic acid .....	1 part.
Ammonio-citrate of iron .....	100 parts.
Water .....	300 "

B.	
Potassium ferricyanide .....	100 parts.
Water .....	300 "

7. There are two forms of the ammonio-citrate of iron, viz., brown and green. The latter, though not easy to obtain commercially, possesses considerable advantages. The following formula is strongly recommended:-

A.	
Ammonio-citrate (green) .....	120 parts.
Water .....	500 "

B.	
Potassium ferricyanide .....	45 parts.
Water .....	500 "

Mix in equal proportions.

Paper thus prepared is estimated to take only one-sixth of the time of that required by paper prepared with the ordinary brown ammonio-citrate of iron.

8. Where the green ammonio-citrate (mentioned under formula 7) cannot be obtained, the solution prepared from its ordinary brown form may have its sensitiveness increased by the addition of ferric oxalate. Thus, of ferric oxalate take 20 grammes, and dissolve in water sufficient to make 100 c.c. Now of the ordinary mixture as given in formula 1 or 2 take 100 c.c., and to this add not more than 2 c.c. of the above-named ferric-oxalate solution (i.e. 20 per cent. strength). Again, in place of the ferric oxalate, we may use the potassio-ferric, sodio-ferric or ammonio-ferric oxalates, the last being supposed to yield the greatest gain in sensitiveness.

9. Another formula which is said to yield a mixture which improves if kept (in the dark) a few days before use is:-

Potassium ferricyanide .....	8 parts.
Brown ammonio-citrate of iron .....	10 "
Sodio-ferric oxalate.....	2 "
Water .....	60 "

10. The following formula is pronounced to yield a paper which will keep in working order for a couple of months if stored in a dry place. Make up solutions "one in ten" of each of the following, viz.:-

Ammonio-citrate of iron.  
Potassium ferricyanide.  
Potassium bichromate.

For use take equal parts and acidulate by adding one or two crystals of oxalic acid. Float the paper and dry quickly.

11. The following is strongly recommended:-

A.	
Ammonio-citrate of iron .....	300 grains.
Water.....	3½ ounces.

B.	
Potassium ferricyanide.....	300 grains.
Water.....	3½ ounces.

Mix in equal parts, and to each 10 parts of the mixture add 1 to 3 parts of a saturated solution of oxalic acid.

12. Another formula said to give a very quick-printing paper:-

A.—Ammonio-citrate of iron (120 grains per ounce). Ammonia added until it just faintly smells of ammonia after shaking.

B.—Potassium ferricyanide, 150 grains per ounce.

C.—Oxalic acid, saturated solution.

Of A and B take 5 parts, mix, and add 1 part of C.

Each of the following formulae is recommended by some eminent authority:-

A.	
13. Potassium ferricyanide .....	1 part.
Water .....	10 parts.

B.	
Ferric potassic oxalate .....	1 part.
Water .....	10 parts.

Take equal parts of A and B.

A.	
14. Potassium ferricyanide .....	10 parts.
Water .....	35 "

B.	
Ammonio-nitrate of iron .....	15 parts.
Water .....	85 "

Take equal parts of A and B.

A.	
15. Boracic acid .....	1 part.
Ammonio-citrate of iron .....	100 parts.
Water .....	200 "

B.	
Potassium ferricyanide.....	100 parts.
Water .....	200 "

Take equal parts of A and B.

An Alternative Method.

16. Take 10 parts potassio-ferric oxalate in 100 parts of water. Coat the paper and print in the usual way. Develop with a 5 per cent. solution of potassium ferricyanide.

Sensitising Fabrics.

The following fabrics may be used for this process:-Linen, calico, silk. The fabric should be very thoroughly washed in plenty of warm water.

If the material is creased, it must be ironed while it is slightly damp.

Next it should be sized by immersing in a (one in 50 or 60) solution of "hard" gelatine—allowed to drain a few minutes and then pinned to a board or stout card to dry.

17. Sensitising mixture:-

A.	
Ammonio-citrate of iron .....	1½ ounces.
Water .....	8 "

B.	
Potassium ferricyanide .....	1½ ounces.
Water.....	8 "

Take equal parts, filter, and apply quickly and evenly with a quite clean hog's-hair brush and dry quickly.

18. Another formula is—of ammonio-citrate make a 25 per cent. solution, and of the potassium ferricyanide a 20 per cent. solution. Of these take equal parts.

19. A more sensitive mixture may be made as follows:-

Of citric acid .....	make a 26 per cent. solution.
Potassium-ferricyanide .....	22 " "
Ferric chloride .....	20 " "

Add 100 parts of the citric acid solution to 100 parts of the potassium ferricyanide solution. Shake and add slowly with constant shaking 40 parts of strong ammonia. Lastly, add 100 parts of the ferric chloride (iron perchloride solution). Apply with a brush and dry quickly.

REV. F. C. LAMBERT.

## ON THE ACTION OF LIGHT ON THE SALTS OF COBALT.\*

### PART IV. EXPERIMENTS WITH COBALTIC OXALATE.

Of all the cobaltic salts the oxalate seems the most suitable for use in the processes of photography. It is best prepared by dissolving, by the aid of heat, well-washed cobaltic hydrate in a concentrated aqueous solution of pure crystallised oxalic acid. The heat must be applied very gradually, and discontinued at the instant when the last trace of the brown hydrate is converted into oxalate, otherwise the newly formed cobaltic salt will be reduced to the cobaltous state. So prepared, cobaltic oxalate forms a beautiful emerald green solution, from which, by evaporation in

\* Continued from p. 660, vol. 45.

*vacuo*, the salt itself may be obtained in the crystalline state. In the cold the solution is remarkably stable, and, if preserved in a dark place, may be exposed freely to the action of the atmosphere even for months without undergoing perceptible chemical change. Heat, however, causes a precipitation of the rose-coloured cobaltous oxalate, the change seeming to be brought about most speedily when the solution is raised to its boiling point. Slight variations in temperature are, notwithstanding, without influence on its stability, and hence the heat experienced during the summer months will not effect its decomposition. When subjected to spectroscopic examination it exhibits a well-defined absorption spectrum, in which the violet and the indigo rays are completely cut off, along with part of the blue, whilst a broad black band supplies the place of the yellow rays.

Several sheets of paper, previously sized with arrowroot starch, were coated with a moderately strong aqueous solution of the oxalate and dried in the dark. One of the freshly prepared sheets was exposed under a negative in bright sunshine, and was found to print very quickly, a distinct pale pink positive image in cobaltous oxalate being impressed in the space of ninety seconds.

By immersing this in a bath of potassium ferricyanide in aqueous solution the colour of the picture was considerably intensified. A mixture of ferrocyanide and ferricyanide of potassium solutions turned the print violet at the margins.

An alcoholic solution of gallic acid turned the deposit to a greenish hue, but at the same time destroyed the clearness of the image.

The sensitiveness of paper sensitised with cobaltic oxalate was found to be impaired by keeping. Two sheets which had been allowed to remain in the dark for a week after sensitising were successively exposed under the same negative, the first for five hours in sunshine, and the second for seven hours in dull, diffused daylight.

Only a very faint image was visible after exposure on sheet number one.

Treated with ferricyanide solution, as in the former case, the paper now merely assumed a bluish-green hue all over, and the image vanished.

The second sheet showed not a vestige of an image impressed by light; but, when developed in an alcoholic solution of gallic acid to which one-third of its volume of water had been added, the details of the picture began to reveal themselves in the course of eight or nine minutes, and, by adding a few drops of aqueous ammonia solution, the progress of the development was much accelerated.

The image formed was of a purple hue, and in the bath appeared fairly vigorous.

When, however, it was removed and washed in water, the depth of the deposit was materially reduced, only a very faint outline of the subject being left. The colour, too, changed on washing from purple to orange-red.

By exposing a sheet of oxalate paper in direct sunshine under a negative for fifteen hours, an image differing slightly from those already mentioned was obtained. Instead of being wholly pink, the details were impressed in pale grass-green upon a pink ground. This green image seemed to be the result of an intermediate stage in a secondary or bleaching action (such as has been already described in the case of other of the cobaltic compounds), for, on being again exposed to light, it was almost obliterated by the time that ten hours more had elapsed. On treating the exposed sheet with an aqueous solution of potassium ferrocyanide, a vivid indigo blue image was produced, which, on washing in water, gradually assumed a bluish-green tint. On drying before a fire, purple streaks made their appearance on the surface of the print, spoiling its original beauty of tone. These seemed to be due to irregular coating in the sensitising operations.

Cobaltous oxalate being rather too pale in colour to give in itself a satisfactory representation of the action of the spectrum, it was found necessary to resort to development in carrying out the under-mentioned spectroscopic experiments.

The first was made by exposing a sheet of the oxalate paper to sunlight in the spectrum slide for a period of four hours. For developer a mixture of aqueous solutions of chrome alum and potassium ferricyanide was employed.

On immersing the print in the developing bath, a vivid blue image was speedily obtained. A graphic representation of this image is shown in fig. 7 of the diagrams accompanying the present article. The maximum

FIG. 7.

effect is in this case exhibited in the region of the blue, and the minimum in the region of the yellow rays. The indigo and the violet rays are little inferior in influence to the blue. The most remarkable feature of

the diagram is, however, the prominent part played by the red rays. In all probability, the actinic activity of that portion of the spectrum is to be largely, if not wholly, attributed to a secondary or reversing action, seeing that the exposure of the print was necessarily somewhat prolonged. In the next experiment the sensitised paper was exposed to the action of light for upwards of thirty-five hours. On removal from the slide, it was divided lengthways into two parts, the first of which was developed in the alum and ferricyanide bath as before, and the second in an aqueous solution of the ferricyanide alone. In both cases a fairly vigorous greenish-blue image was produced, that obtained in the chromium bath being rather less intense than the other. Fig. 8 represents the spectrum

FIG. 8.—COBALTIC OXALATE.

produced by the simple ferricyanide developer. The point of maximum activity again appears in the blue, but the minimum has shifted from the region of the yellow to that of the green rays, while the former influence of the red rays has, so to speak, undergone a process of levelling down, and what still remains of it is now shared with the yellow and the orange rays. There is also a considerable weakening of intensity at the more refrangible end of the spectrum, the violet rays in particular being divested of much of their actinic power, as will appear by comparison with the companion figure.

The range of intensities shown on the strip that was developed in the alum bath was in all respects similar to that exhibited in fig. 8.

The chemical reaction involved in the decomposition of cobaltic oxalate by light is precisely analogous to that which occurs when ferric oxalate is decomposed under like conditions.

In the latter case the products are ferrous oxalate and carbon oxide; in the former, carbon dioxide and cobaltous oxalate.

The action of light or heat on the cobaltic salt may therefore be represented by this simple equation:—

In the case of the iron salt the reaction, of course, is:—

which, it will be seen, differs from the first equation only by the substitution of two atoms of iron for the two atoms of cobalt. The compounds formed by the union of cobaltic oxide or hydrate with tartaric, acetic, citric, and other organic acids also give off carbon dioxide on their reduction by light to the cobaltous state; but, generally speaking, the reaction in such cases is more complicated than that representing the decomposition of the oxalate, owing to the formation of additional by-products. As might be expected, this is found to apply with equal force to the corresponding ferric compounds of these acids.

Like cobaltic citrate, cobaltic oxalate is powerfully acted upon by light in the presence of potassium bichromate, forming an image which is gradually bleached under the further influence of the actinic rays. As an illustration of the behaviour of the salt under these circumstances, the following experiment, as being a typical one, deserves notice:—

A sheet of unsized paper, which had been first coated with an aqueous solution of the dichromate and dried in the dark, was sensitised with the oxalate, and, when dry, exposed under a negative for fifteen minutes in bright sunshine. A green image was obtained, all the details of which were perfectly distinct and fairly satisfactory in the matter of density. On exposing print and negative again to light, there was for a little time a gradual, but perceptible, increase in the depth of the colour of the image; but soon a bleaching action began to make itself apparent, and at the expiry of three hours the picture had almost disappeared from view. On treating the print thus over-exposed with a solution of potassium ferricyanide, the image was speedily rendered invisible, owing to the formation of a pale plum-coloured deposit, in all probability a mixture of the ferricyanides of cobalt and chromium. A little tannic acid in aqueous solution was next added to the developer; but, as this produced no change in the appearance of the print, the latter was removed from the bath and, after washing in cold water, treated with a weak aqueous solution of ammonia. By the action of the alkali the image was again rendered visible, though only faintly so, its colour being now, however, a pale grey.

Cobaltic oxalate, it should be mentioned, is non deliquescent, a circumstance which serves to enhance its other merits as a sensitising agent.

*Experiments with Cobaltic Lactate.*—The salt employed in the present series of investigations was prepared by double decomposition. Unsized paper was coated, in the first instance, with a solution of cobaltic citrate

and dried in the dark. A strong aqueous solution of sodium lactate was then applied to the prepared surface by coating, and the paper was again laid aside to dry. It was found, however, that the cobaltic salt thus formed possessed too great an affinity for moisture to permit of the desiccating process being successfully carried out. When the drying was nominally at an end, the paper still retained enough water to render it perceptibly damp, and during the exposure to light it absorbed additional moisture from the atmosphere, assuming towards the close of the operations quite a pulpy condition.

In the first experiment with the lactate the sensitised paper was exposed beneath a negative in sunshine and diffused light. In about twelve hours' time a fairly strong image, of a brick-red colour, was produced, the details of which were, however, considerably blurred, owing to the solvent action of the absorbed water. On gradually increasing the exposure, the picture underwent but little alteration, nor, even after several hours more had elapsed, were any signs of a reverse or bleaching action apparent.

In the second experiment the paper was exposed for a like interval and under similar conditions to the action of the spectrum. As before, a somewhat blurred reddish image was obtained. Of this fig. 9 affords

FIG. 9.—COBALTIC LACTATE.

an approximate graphic representation. Here the point of maximum intensity is again situated in the blue. There are two points in the spectrum representing the minima, the one in the red and the other in the green rays. The indigo and the violet rays rank next to the blue in intensity, and after them the orange rays, all three exercising a comparatively strong influence. The power of the yellow rays is somewhat feeble, being only one-half of that due to the violet or indigo rays.

In order to produce an image by "printing out" on the lactate paper, it seems necessary that the paper should be used as soon after sensitising as possible. If kept for a few days, little or no visible reduction is effected by exposure to light; but, instead, a latent image is impressed, which may be developed by suitable means. The following experiments were made with paper which had been kept for from two to three weeks in darkness after sensitising.

Three sheets were exposed in succession to the action of the spectrum, an exposure of thirty-six hours being given in each case. The first of these was immersed for ten minutes in a bath containing potassium-ferrocyanide solution, but no image could be perceived. The second sheet was soaked for a few seconds in potassium-ferrocyanide solution, whereupon a distinct violet-grey image manifested itself. The range of intensity thereof could not be determined with exactitude, but it was noticed that the maximum action was due to the green rays. The developer was next rendered strongly alkaline by the addition of an aqueous solution of caustic potash, and the third strip was then transferred to the bath. An image very similar to the last was immediately obtained, the green rays again appearing to exercise the predominant influence, and the yellow rays one of almost equal intensity.

By reason of its peculiarly hygroscopic character, cobaltic lactate must be placed in the category of photographic curiosities rather than in that of salts available for practical printing purposes.

#### EXPERIMENTS WITH COBALTIC FERROCYANIDE.

Unsize paper was sensitised with a strong aqueous solution of potassium ferrocyanide, and, after drying in darkness, with a weak solution of cobaltic citrate. After drying a second time it was found that there was a very slight reduction of the cobaltic salt, indicated by the paper's having assumed a uniform tint of very pale green.

On exposing a portion of the sheet under a negative to diffused daylight for a few minutes, a very distinct yellowish-green image, due to cobaltous ferrocyanide, was produced.

On treating this picture with an aqueous solution of stannic chloride, the green colour became slightly stronger, but no gain in contrast ensued. During this process minute bubbles of a gas were evolved from the coating of the paper, perhaps due to the conversion of the unreduced cobaltic ferrocyanide into the unstable chloride, the latter a salt which very readily parts with portion of its chlorine.

A second ferrocyanide print was washed over with a weak aqueous solution of potassium permanganate, whereupon the green image was replaced by a violet-coloured deposit, through which the details of the picture could be traced only with difficulty.

A third and similar print was immersed in an alcoholic solution of gallic acid, but no change of colour was apparent, nor were there any

signs of intensification of the image already deposited. An aqueous solution of calcium hypochlorite was also found to have no visible influence upon the ferrocyanide picture. A fifth print was soaked for half an hour in an aqueous solution of disodic orthophosphate rendered alkaline by the addition of ammonia. A reddish-brown deposit was gradually formed, but, instead of being intensified, the details of the image were considerably obscured. A sixth print, on being immersed in an aqueous solution of cupric chloride, changed hue from green to purple-brown, but the relative intensities of light and shade remained unaltered.

The ferrocyanide was next subjected to spectroscopic examination. For this purpose paper was coated with a special solution of cobaltic ferrocyanide, made by adding cobaltic oxalate in the necessary combining proportions to a strong aqueous solution of potassium ferrocyanide. When dry, the sensitised sheet was exposed to the action of the spectrum in the usual manner, an exposure of six hours being, however, given, in order to obtain a sufficiently vigorous image. As before, the colour of the picture was a light green, inclining to yellow or yellowish-brown in the regions where the light had exercised the least action. A representation of this ferrocyanide spectrum is given in fig. 10. The violet rays, it will

FIG. 10.—COBALTIC FERROCYANIDE.

be noticed, exercise the strongest influence, after which the blue and the indigo rank next in power. There are again two minima points, the one in the red, the other in the green, both sets of rays being practically inoperative. On the other hand, the yellow, and, to a less degree, the orange, rays exert a fair share of chemical action. The superficial resemblance which this spectrum bears to that of the lactate is also worthy of note.

Some further experiments were made with the ferrocyanide in combination with cobaltic iodide. These will be noticed in a later article describing the reactions of the haloid cobaltic salts.

#### EXPERIMENTS WITH COBALTIC FERRICYANIDE.

Cobaltic ferricyanide, *per se*, appears to be little sensitive to actinic action. An experiment was made by sensitising a sheet of unsized paper (1) with a solution of cobaltic citrate, and (2), after drying, with a strong aqueous solution of potassium ferricyanide. After the second drying it was found that the ferricyanide had partially reduced the cobaltic compound to the cobaltous state, thereby producing a pale reddish-coloured deposit. Exposure of this paper was made under a negative in bright sunshine for upwards of seven hours, but no image whatever was produced, nor, by immersing the paper after printing operations in a second bath of the ferricyanide solution, was any change effected in its appearance. Paper was next coated with the ferricyanide solution and allowed to dry, then sensitised a second time with a solution of cobaltic citrate to which a drop or two of acetic acid had been previously added. The cobaltic salt was again reduced without access of light, this time to such an extent as to render the paper useless for photographic purposes. The operations last mentioned were then repeated upon paper which had been previously sensitised with an aqueous solution of potassium bichromate. After drying, the sheet was found to have assumed a red or reddish-violet hue of considerable depth, due as before to the formation of cobaltous ferrocyanide. This prepared paper was exposed under a negative for from thirty to thirty-five hours in sunshine and diffused light. The resulting print was of a unique and extremely curious character. The sensitised surface was found to have been bleached almost white in the portions which had been least exposed to actinic action, i.e., in those parts representing the high lights of the positive image. The red ground or field, on the contrary, seemed to have suffered little alteration. The image, in fact, was wholly due to the disappearance, to a greater or less extent, of the original coloured deposit formed in the dark. The back of the print, however, was found to bear a positive image of a rich and deep purple colour, the high lights of which were represented by the yellow of the unchanged dichromate substratum. Portions of the print were treated with aqueous solutions of various reagents. No visible alteration was produced either by disodic orthophosphate and ammonia, or by calcium hypochlorite, whilst stannic chloride produced but a slight change. Potassium permanganate gave a brown colour, but, as usual, its action on the paper destroyed the clearness of the picture.

The experiment above described has a certain theoretical interest, demonstrating as it does that light may exercise a bleaching action upon a cobaltous salt in cases in which the primary action resulting in the formation of the compound has been performed in darkness by quite a different agency, as for instance, by thermal action, chemical forces, or change of molecular state.

## ALPINE PHOTOGRAPHY.

It is a common saying that some subjects are far more suitable for photographic illustration than others, and, if we were to analyse the matter, we should probably find that it is merely a question of colour. For example, a greenhouse full of brilliantly petalled flowers would be deemed less favourable to camera interpretation than the chiselled front of a grey cathedral. The same thing holds good with regard to snow and ice pictures, taken at high altitudes, which are rendered far more truthfully by photography than are the plains below, where a variegated vegetation presents difficulties which are familiar to all. Indeed, it may be said that there is no class of work which gives more satisfactory results to the photographer than those taken above the snow line in mountainous districts.

But there are snow pictures and snow pictures, some that we have seen being of the chalk-and-soot kind, and others, taken by experienced hands, being as soft and delicate in gradation as it is possible to obtain them. In the latter category must be placed the extremely beautiful series of slides which illustrated a discourse by Dr. Anderson at the Camera Club on Monday last week, each one of which was a gem of the first water. And no one was prepared for such an excellent display, for the notification of the lecture merely said that it was a discourse about glaciers and glacier action. A subject such as this is apt to impress the ordinary mind with the idea of dry, scientific facts, but Dr. Anderson, who is a prominent member of the Alpine Club, and an enthusiastic climber, invested the story with the interest of a fairy romance, and his audience, whether owning alpenstocks or not, thoroughly appreciated both the story and the pictures which so ably illustrated it. And the story is a fairy-like and pretty one. The glaciers are born in the clouds, for it is the moisture condensed from the vapours which hang among the cold peaks that forms the snow and ice spicules which give them their origin. Then the snow and ice become compressed into a solid mass, looking more like crystallised sugar than like the black ice that we are accustomed to see on the lakes and rivers. The mass is heavy, and it begins to slowly slide down the mountain sides, forces its way between the rugged peaks, gets more and more broken up on its journey, and affords magnificent effects as the sun's rays slant along it and show the crevasses which gradually tear it asunder. Then the hot beams of the sun begin to act upon the surface, and the glacier is cut up with running streams, which sometimes form a thundering waterfall when the course of one is interrupted by a crevasse. But these are only episodes in the journey of the main mass of ice, which flows imperceptibly towards the level of the plains below. It is these episodes which Dr. Anderson illustrated so grandly by means of his pictures. Not a point of any interest was missing. A tumbling stream of to-day was the bulky icicle of the morrow, and the pictures were shown in such complete series that it was easy to understand the working out of problems which, in days of old, were shrouded with mystery and superstition.

The trailing glacier itself, with its huge scales and sinuous tail, was a dragon which ruled the destinies of the mountain valleys, and no one had penetrated the zone of enchantment lying beyond, up among the mountain peaks. To-day the scientific explorer and the photographer join hands to make these once mysterious things understood by all, while at the same time the sense of vision is gratified by the natural beauties revealed by the camera. The glacier is presented as a sea of hummocky ice, with its bending dirt bands showing how it moves more quickly at the centre than at the sides, and its carried *débris* in the form of lateral and median moraines.

Dr. Anderson did well to take several of his finest views shortly after sunrise, when shadows were long and every speck on the snowy surfaces was rendered apparent. He used for all his views medium isochromatic plates, the value of which for this kind of subject has long ago been acknowledged. For snap-shots only did he employ rapid plates of the ordinary kind, and some of these, notably those of the villagers, were extremely good, and in some cases entertaining. It is also to be noted that Dr. Anderson, for his Alpine views, made good use of the tele-photo lens, and a comparison of the pictures so obtained with others taken from the same position with an ordinary lens attested the value for mountain work of the former. Some of the views were taken with the sun in front, and very beautiful effects were thus obtained, owing to the intense illumination of the upper edges of the ice and snow ridges. Much interest was also aroused by the pictures of glacier tables, huge masses of rock supported on pillars of ice, the table top so formed protecting the ice pillar from the rays of the sun. And thus, giving his audience every opportunity of seeing what he described, Dr. Anderson brought them to the foot, or rather "snout," of the glacier, where it forms into fairy caves, from the hollows of which issue streams of muddy water, the source, it may be, of a mighty river.

So far Dr. Anderson dealt with glaciers of the first order of merit, but there are minor ones which fill up the depressions in a mountain-side and will sometimes come thundering down *en masse* on a devoted village. One of these he showed us, which assumes this dangerous condition about every hundred years. Its last escapade was in 1872, when it buried 150 cattle and their caretakers.

It was not the least interesting portion of the lecture which showed that similar incidents which are occurring in Alpine districts to-day took place during the great ice age in Yorkshire and our other northern counties. Glacier action there has left its marks on the rocks just as it

is scoring the limestone of the Swiss valleys now. This point was made clear by several comparative pictures. The proceedings were listened to with rapt attention, and Dr. Anderson was the recipient of a hearty vote of thanks.

Tuesday week was a Ladies' Night, and the Club had the great advantage of the help of Miss Marian Mackenzie, whose vocal efforts, it need hardly be said, gave much pleasure to all. In addition to an excellent concert, there was a lantern show, a cinematograph exhibition, besides a phonograph and X-ray demonstration.

## THE WEISS FLASHLIGHT APPARATUS.

At the Photographic Club, on May 8, Mr. Reinhold Thiele addressed the meeting on the subject of flashlight photography, and instantaneous flashlight photography in particular, referring to the faults and shortcomings of artificial lights in use, all of which the new Weiss apparatus claims to have overcome. The electric arc light, with its immense actinic properties, is yet far from being a satisfactory illuminant, especially with nervous persons and children, its liability to contort the features and encourage an unnatural expression being serious obstacles to its general use. Its great brilliance also tends to an undesirable flatness in the portrait, whereas our aim is always to get a result as nearly like that produced by daylight as it is possible to do. Another factor which operated against the electric light was the comparative difficulty of transport, energy not being obtainable at all times and in every place. Added to these must be the matter of cost, which is high, and the fact that there was an essence of unreliability about electrical apparatus. The incandescent electric light is one which necessitates a long exposure, besides being very poor in ultra-violet rays, although rich in red and yellow. Magnesium blow lamps Mr. Thiele generally found unreliable. More often than not the lamp becomes clogged, and any attempt to use it in such a condition results in failure. If it goes off, a continuous flash of some duration is given, almost always causing a movement of the eyes and features visible in the photograph. The problem that presented itself was to obtain a flash of sufficient rapidity to prevent any involuntary closing of the eyes or contortion of features from showing in the resulting picture. Such a condition of things was only possible with exposures below a thirtieth or a sixteenth part of a second, and, with the apparatus and flash powder shown, this had been brought within possibility. The apparatus consists of a telescopic stand, devised for clamping it to the edge of the table, or other convenient support. On the topmost rod is fixed a platform, which, when large groups are being taken, may be extended on either side by means of secondary detachable platforms. The flash powder, which is an extremely finely ground mixture of aluminium and other ingredients, is laid in a train along the platform, the quantity being regulated by the usual factors. At the back of the platform is fixed a trigger, to which a good-quality Swedish match is attached, while in a receptacle is placed the box, with its frictional side directed to the match in the trigger. The trigger is released, the match strikes the box (turning it aside) and ignites, and the intense heat of the consuming head instantly ignites the train of powder, and the exposure is made. The height of the stand is regulated by the telescopic device according to the distance of the sitter. The usual lights of the room are best kept burning, as they materially help the sitter to retain a natural expression. The powder is one possessing a large degree of safety. Concussion and friction fail alike to produce ignition, an intense heat being required. Rapid plates should be used, and they are best backed. It may be mentioned that Mr. Thiele uses red ochre and starch paste for this purpose. Specimen portraits and groups were passed round to show the capabilities of the apparatus, and on another occasion a group will be taken by means of the lamp. A vote of thanks was passed to Mr. Thiele.

## FUCHS' METHOD OF PRODUCING PHOTO-MECHANICAL PRINTING PLATES.

The new method of producing printing plates is principally designed to be employed for producing deep-etched zincographic plates for use in revolving presses even of the greatest production, as employed in printing daily newspapers. Plates of this kind, hitherto, could only be obtained by the aid of open and deep-cut xylography and by deep-etched pen-and-ink drawing on zinc. Owing to the slow and expensive hand work required for producing such printing plates, no use, or but very little use, could be made of them for usefully illustrating the most recent events of the hour in the daily journals printed by revolving letter presses of highest speed.

The photo-mechanical method of producing deep-etched zincographic printing plates of the kind of deep-cut xylography, as hereinafter described, allows of the reproduction of figurative objects of every kind in a way so quick and cheap as to enable such reproductions to be employed for illustrating the daily journals printed by revolving presses.

The new method of the invention, as stated before, is performed by the employment of a quadruple camera obscura, as represented in the accompanying drawing. A chamber of suitable size, perfectly closed

to shut out all light from outside, is divided into two compartments, 2 and 3, by means of a partition, c, which is conveniently movable, by the aid of rollers or wheels, to or from either end of the chamber. One end wall, a, of said chamber contains an aperture, b, so constructed and arranged as to receive a frame, which contains the original figurative object to be reproduced. Such object must be translucent, and may consist of a negative photograph, or any design, tracing or printing prepared for the purpose, or other translucent picture. The said original is tightly fitted in its frame, and the frame equally tightly placed within the aperture, b, so as to prevent any ray of light from entering into the compartment 2 except through the translucent original. A source of light of sufficient intensity is placed behind the said original, the reproduction of which, through an

objective glass placed in a camera, 1, within the compartment, 2, is projected on an enlarged scale against the partition, c, which contains an aperture holding a pane of translucent glass or other suitable material. The said partition, c, being adjustable to and from the aperture, b, and camera, 1, the size of the projected picture may be easily determined. Opposite to the said aperture of the partition, c, a photographic camera, 4, is placed, adjustable both in height and to and from the said partition, c.

On the opaque pane in said partition, c, appears, as described, the enlarged picture of the original, extending with broad shades, half-tones and lights, and, owing to the interruptions of the small sharp reflections of light, the said picture on the pane resembles, by itself, a perfectly true but enlarged engraved reproduction of the original.

To complete the picture thrown, as described, on the pane of the partition, c, for the requirements of open zincography, a fine screen or screens, v, are placed before or behind, or before and behind the said pane in the partition, c, and thereby the picture thrown on said pane is finely divided and detailed into a net of sharp lines, such as the xylographer obtains by minutest attention, working by hatching and cross-hatching the wood with the aid of gravers.

The picture thus produced on the translucent pane of the partition, c, and subdivided by a suitable screen or screens into a net of fine points, lines, and squares, being suitably adjusted, is subjected to photographic exposure by the camera, 4, within which the said picture is again reduced to any desired scale, and the negative obtained serves for applying the picture to the zincographic plate to be etched in the usual manner.

The method hereinbefore described is adapted to be employed in a great variety of ways, to reproduce drawings and figurative objects of any kind, and in applying a screen or screens, as described, and adapting such screen or screens to the original to be reproduced, printing plates of any kind and description, for plate presses, typographic and lithographic presses, may be produced, not only for the usual journal printing, but also for producing the finest artistic and coloured prints.

### THE SILVER PRINTING BATH.

Those who still print on albumenised paper need to be careful to keep the silver sensitising bath in good order if they sensitise for themselves, which is as a rule the surest way to secure good results; and to compete with other styles of printing it is necessary for everything to be in good order.

First of all, then, we must have suitable water, and see that we dissolve the proper quantity of nitrate of silver. Find out, if possible, from the maker of the paper the proper number of grains to the ounce of water, and, having weighed out the requisite quantity, put a pinch of tow into a glass funnel and press it into the tube, then put the crystals on it and pour the water in, warm, not hot, this melts the silver at once. Now add, for every ounce of water, half a grain of carbonate of magnesia, shake the bottle and allow to stand till clear. The magnesia has a

double duty to perform; it will keep the bath from being acid unless the silver crystals were very much so, and in this case more must be used to render it quite neutral. Secondly, the magnesia will prevent the bath from becoming coloured, especially if the printing room is not very warm.

If the bath becomes coloured by use, the best plan is to pour it into the bottle, retaining the carbonate of silver formed by adding the magnesia, and, if necessary, add a little more, and then stand the bottle in a good light for a day or two, this will throw out the colour and render it white and clear.

To keep up the proper strength of the solution it is a good plan to add a few grains of nitrate of silver for every six sheets sensitised as soon as the six are completed, because, if the bath becomes weak, the prints will be weak.

If the solution in drying runs into drops, the bath is too strong and water must be added; also it is best to float the paper for a shorter time.

If the prints on removal from the printing frame look unusually red and flat, the bath is too weak; but, if the shadows show a brassy lustre, the bath is too strong. In either case it is important to correct it before another sheet is sensitised. If too weak, throw in a small quantity of silver nitrate; if too strong, add a little water. Experience will soon show the proper quantity.

The best way to dry the sheets is to fix flat strips of cork along a wall opposite to the fire in the printing room, and pin the sheets to it by the two top corners with black pins, as these do not stain the paper in any way; common pins will reduce the silver to the metallic state, and often make spots and streaks; one corner should be the lowest, in order to drain the sheet, and a saucer or trough should be under it to receive the drainings. This solution should be either returned to the stock bottle, or, what is better, it should be put into a separate bottle and placed in a strong light for some days to clear itself, which it will soon do, and may be filtered off clear and white; it may then be added to the stock.

After prolonged use, it will be found well to throw an old bath down as chloride of silver with common salt, and send it to the refiners with other residues, and it is well to add to the bath before the salt a few drops of a solution of bichromate of potash; this makes the solution brick red, and a saturated solution of salt is now to be added till the red is destroyed. The red or pink tint will remain till all the silver is turned into chloride of silver.

ALFRED SEELEY.

### THE PHOTOGRAPHIC SURVEY OF SURREY.

At the Technical Institute, Redhill, on Tuesday, May 2, an interesting meeting was held under the auspices of the Redhill and District Camera Club, and in connexion with the proposed Photographic Survey of Surrey. The paper prepared by Mr. Geo. Scamell, the Hon. Secretary of the National Photographic Record Association, was read by Mr. J. Sterry, the Vice-President of the Club.

The paper stated that the object and value of obtaining a series of permanent photographs for historical reference was now sufficiently understood and acknowledged, and it was therefore needless to dwell on that point; but if there should be any doubt as to whether any object or scene were worth recording photographically, one could ask the question, "What would be the present value of a photograph of such a class of subject taken, say, a century or more ago, if such had been possible?" for example, how much the interest of Pepys' Diary would have been enhanced if illustrated with photographs of the customs, people, and places of the period. If such would prove of interest to us, we might be sure that similar ones of our own time would prove valuable to those who came after us; the trivial subjects of to-day might become of the greatest value years hence. The value of record work being acknowledged, it was to be hoped that, before long, photographic survey work would be taken up by every county in Great Britain. One of the first, if not the first, of the societies formed for the purpose was the Warwickshire, and since then it had been followed by societies in Yorkshire, Somersetshire, Worcestershire, and Guildford, and also by the congress of the archaeological societies in connexion with the Society of Antiquaries, the Committee for the Survey of the Memorials of Greater London, and by the National Photographic Record Association. This Association was started in London by Sir J. Benjamin Stone in July 1897, and a committee was formed to carry out the objects of the Association, viz.: To establish a national collection of photographs to form a record of existing objects of interest throughout the British Isles, the same to be deposited in the British Museum for public reference. The scheme allowed a very wide scope, as every class of subject or object that might be of use to the future historian or man of science would be included. Ethnological subjects should have special attention, such as dress, occupations, amusements, local customs or celebrations. In particular, records should be secured of such customs as are in a state of transition (such as the use of the flail, the plough, the churn, &c.), street scenes, various methods of locomotion, sailing and steam-ships, and railway rolling stock. All these were suitable subjects for photographing. Abundant work would also be found in the architectural details of our old cathedrals, among the ruins of our ancient castles and abbeys, in old and modern churches, in old monuments and the inscriptions upon them, ancient mansions, old manor houses, tithe barns, labourers' cottages, village scenes, &c.,

as well as illustrations of the homes of the present generation; also any interesting archaeological subjects, including old manuscripts and articles of general or domestic use. Photographs of objects of natural history, and of landscapes or geological features would also be accepted, while the photographing of portraits of celebrities, already begun by the Warwickshire Society, might also prove of great value in times to come.

Besides the workers who might take and collect photographs, there were those who, though not photographers, could help by preparing a list or register of objects of architectural, historical, or archaeological interest in their neighbourhood, by making known the observance of any local custom or ceremony, and particularly by calling attention to the threatened destruction of any ancient building or monument. There was also another class who could render valuable help, namely, those photographers who possessed—as no doubt many did—a large number of negatives. If they would only look through their stock, no doubt a mine of wealth would be brought to view that was now hidden and useless. An important part of the work was to promote the interchange of experience as to the best method of working the survey societies, to prevent the overlapping and duplicating of work, and to ensure uniformity of result. For the purpose of organizing the work, it would be convenient to divide the country into districts, which might well consist of counties, and these, in their turn, might be subdivided when necessary. It might also be desirable to introduce a union of two or more counties into provinces, such as the Northern, Western, Welsh, &c. In each of these districts a strong central committee would be formed, consisting of representatives of the various photographic, archaeological, antiquarian, and other societies, whose business it would be to take the general direction of the survey, to form local committees, divide the country up into districts, arrange for the work of the various photographic societies or amateurs who might be willing to assist, prepare a list of objects to be photographed, and perhaps arrange for an annual exhibition before sending the photographs to the museum.

A number of photographs were then shown by the aid of the lantern. Among the pictures were photographs of the Old Inn at Chiddingstone, the Kew Bridge, which is about to be removed and replaced by a handsome structure more in accord with the requirements of modern times, and the old lock and foot bridge at Richmond. Old cottages at Smallfields were mentioned as well worth photographing, as also were the old cottages in West-street, Reigate, which seem likely to be removed. An interesting and amusing set of photographs were those depicting street hawkers and small traders, such as newspaper boys, purveyors of cats' meat, muffins, chestnuts, &c.

In the course of a short conversation which followed, Mr. Penfold produced an interesting photograph of a portion of Reigate taken thirty-five years ago, and also a sketch of an old dungeon which has been discovered under the old Reigate Town Hall, and which, apparently, was built about the thirteenth century. Mr. Penfold also mentioned that there were a few old prints of Reigate still extant which might be photographed.

#### A NEW WEIGHTS AND MEASURES BILL.

We are indebted to our contemporary, *The Pharmaceutical Journal*, for some particulars of Mr. Bousfield's Weights and Measures Bill, which does not violently disturb the existing Acts of 1878 and 1889, but it supplements them to a very considerable extent. "Cased" weights—that is to say, lead or pewter weights cased with brass, copper, or iron, as provided by Section 30 of the principal Statute—are to be abolished, and their use made illegal, presumably because the material and mode of construction of such weights are considered likely to facilitate the commission of fraud. Compulsory periodical reverification is another of the points which the promoter of the Bill deems expedient for the protection of the buying public, and he proposes that the Board of Trade shall prescribe regulations for ensuring that all weights and measures and weighing instruments used for trade shall be reverified not less than once in three years. It may be anticipated that considerable opposition to this proposal will be forthcoming from traders, and perhaps from local authorities, for few retailers will view with philosophic equanimity the prospect of additional visits from public officers of the inspector type, and, on the other hand, local authorities are not, as a rule, prone to regard with favour projects involving increased expenditure.

True, reverification will cost the trader nothing if his stamped weights be found correct, but a much larger number of inspectors and reverification officers will be needed to see that the law is properly carried out, and multiplication in this connexion cannot be recommended. From internal evidence there is reason to believe that the Bill is inspired by the Incorporated Society of Inspectors of Weights and Measures, in conjunction with the manufacturers of weighing and measuring instruments, and, if this assumption be correct, the measure would be invested with a heightened value as embodying the opinion of experts. The Bill would not interfere with weighing instruments used for scientific purposes and not for trade, but it proposes to bring Post Office weights and scales within the scope of the Weights and Measures Acts.

#### THE DERBY EXHIBITION.

We append a list of the names of those who have accepted the invitation to exhibit at the forthcoming Derby Exhibition.

The Exhibition will open about June 6, and exhibits from the London district will be called for by the agents, Messrs. Bourlet & Sons, 17, Nassau-street, W., on May 31 or June 1, or at any time before those dates if a post card be sent to them. The last day on which exhibits from any part of the country will be received at Derby is Friday, June 2. Carriage both ways will be paid by the Corporation. There will also be a section confined to the members of the Derby Society, which will be largely supported.

The Exhibition will remain open three weeks and close not later than Saturday, July 1.

The frames will be handled and packed at Derby by experienced men who are accustomed to handle the thousands of pounds' worth of pictures sent every year to the recurring exhibitions in this gallery.

Names of photographers who have accepted the invitation to exhibit at the Derby Corporation Photographic Exhibition, June, 1899:—

Wm. Crooke.	Harold Baker.	Hay Cameron.
Chas. Job.	W. Smedley Aston.	Jno. Carpenter.
Karl Greger.	J. Crawys Richards.	J. Gunston.
J. H. Avery.	J. Page Croft.	W. Rawlings.
J. Craig Annan.	T. Morley Brook.	W. A. J. Hensler.
A. Horsley Hinton.	Rev. F. C. Lambert.	Geo. Hankins.
Viscount Maitland.	F. A. Bolton.	Geo. Bankart.
Percy Lund.	S. L. Coulthurst.	Ernest Marriage.
W. Thomas.	Dr. Llewellyn Morgan.	H. W. Bennett.
F. M. Sutcliffe.	John Bushby.	C. F. Inston.
John Westworth.	T. Lee Syms.	A. J. Jeffreys.
Paul Martin.	Fredk. Hollier.	J. H. Coath.
Miss Muriel Bell.	M. Tuke Tylor.	F. H. Evans.
W. D. Welford.	W. T. Greatbatch.	J. B. B. Wellington.
Mrs. Welford.	Fred. Marsh.	A. Brothers.
Reginald Cragie.	W. Edgar.	R. L. Warham.
C. S. Baynton.	Percy Lewis.	S. B. Bolas & Co.
E. Evelyn Barrow.	J. Kearney, jun.	J. A. Sinclair.
Alex. Keighley.	Rev. C. F. L. Barnwell.	

Mr. F. M. Sutcliffe, of Whitby, has promised to act as Judge in the Local Section.

#### PHOTOGRAPHERS' BENEVOLENT COMMITTEE.

A MEETING of the above Committee was held on the 3rd inst. at the Photographic Club.

Among the cases was that of a photographer who, through illness, had become an inmate of an infirmary. Having the necessary apparatus, on his recovery he simply needed a few pounds to enable him to obtain materials with which to start work. The money required was voted.

The case of a photographer, to whom a small weekly allowance had been temporarily granted, was further discussed, and the Honorary Secretary was directed to make inquiries as to whether a home could be found for him on payment of a small sum per annum. The Hon. Treasurer made a report concerning the orphan child, for whom an annuity has been purchased, which, together with the contributions of a gentleman who has interested himself in her, will enable her to be kept and educated for the next ten years.

A case of want through serious illness was also dealt with, and, as this appeared to be one of the most deserving applications that had come before the Committee, a sum for relieving the immediate necessities was granted, and the case referred back for further considering how assistance might best be given.

#### Our Editorial Table.

##### BURTON'S MODERN PHOTOGRAPHY.

Twelfth edition. 206 pp. Price 1s. London: Carter & Co., 5, Farnival-street, E.C.

This is really a new edition and not a mere reprint of Burton's very popular little book. As we turn over its well-written pages we can mark the parts where the pruning knife has traced a sharp course and new matter has had to be written in. Some chapters on amateur dry-plate making, which were a feature of previous editions, have been omitted, and there are several pages devoted to new lenses. But, for all the care which has been expended on its revision, so rapidly does photography move nowadays, that the up-to-date London reader must regard even Burton's book as somewhat behind the times, Velox, ammonium persulphate, and other recent departures in practice not being mentioned. These omissions, however, can hardly rank as drawbacks to the general reader, and do not detract from the solid value of Burton's book, which, in virtue of the sound and well-digested information it gives on practical photography, takes rank as a classic.

## THE FOLDING APEK.

Agent: WILFRED EMERY, 8, Dyne-road, Brondesbury, N.W., and 3, Soho street, W. The latest production in this elegantly made series of cameras has been shown us by Mr. Emery. The No. 0 is a 5 x 4 camera, hand or stand, measuring when closed only  $2\frac{1}{2} \times 6\frac{1}{4} \times 5\frac{1}{4}$  and weighing 1 lb. 13 ozs. It

is fitted with a single lens of excellent quality and a pneumatic shutter giving three speeds, i.e. time, bulb and variable instantaneous exposures. The price complete with three double slides and leather case is 50s. A careful examination of the camera and its movements convinces us that it is excellent value for the money, and can be recommended for its special purposes.

## SPECIMENS OF TRADE PRINTING, &amp;c.

Catherall & Prichard, Limited, 326, Camden-road, N., and Chester.

MESSES. CATHERALL & PRICHARD, the well-known view-publishers, to whose stereoscopic slides we recently had occasion to make favourable reference, inform us that they have added to their business a department for trade printing and negative-reproducing in addition to other kinds of work for the trade. They have been good enough to send us some samples of their work, prints taken from a day's toning of about 100 sheets and duplicate negatives from stock. The prints are on ordinary albumenised paper, which Messrs. Catherall & Prichard say they find their customers prefer to chloride.

These neatly mounted prints are mostly of whole-plate size and have a pleasing variety of tone. The subjects are landscape and architecture, and in the corners of some of the prints we see the honoured name of "Bedford," at one time a very potent force in professional photography. We have no hesitation in saying that, as specimens of clean, well and evenly toned albumen paper printing, we have never seen anything better than the samples Messrs. Catherall & Prichard have sent us. By a happy inspiration the firm ask our acceptance of a set of four negatives, two landscape, two architectural. Very rarely indeed do little offerings of this nature find their way to this table, which in its time has borne the weight of a vast number of spoilt negatives and prints. Of the very beautiful negatives we are here acknowledging, the best deserved thing we can say is they are so good that they are fit to show many a photographer what he should aim at in definition, gradation, and brilliancy of image, and freedom from the smallest trace of fog or veil. We wish Messrs. Catherall & Prichard success in the new department of their business.

We have also received the Kodak and general price-list for April; Royal Ascot, a Visit to the Royal Ascot Hotel; catalogue and illustrated description of the Biokam (the Warwick Trading Company, Warwick Court, Holborn); and *Dix Leçons de Photographie*, by E. Trutat (Paris: Gauthier-Villars).

## News and Notes.

PHOTOGRAPHIC CLUB.—May 17, "Flower Photography," by Mr. H. T. Malby.

ROYAL PHOTOGRAPHIC SOCIETY.—Photo-mechanical Meeting, Tuesday, May 16, at 12, Hanover-square, at eight p.m. "Specimens of work with Irregular-grained Screens," &c.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday next, May 18, Mr. Child Bayley will read a paper on "Exhibitions, Technical and Otherwise." The Hon. Secretary will be pleased to see any one interested in the subject. Meeting at eight o'clock. Visitors are always welcome.

A LOCOMOTIVE head light using acetylene gas has been devised by a Canadian inventor. The apparatus consists of a cylindrical cast-iron generator, five inches in diameter and twelve inches long, together with a water reservoir and condenser. The charge consists of about ten pounds of carbide, which is put in a wire basket and placed inside the generator. The water from the reservoir, dropping on the carbide, generates the gas, which is led through a small pipe in front of the reflector.

MR. F. AHRLE, Managing Director of the Metallic Photo-printing Syndicate, Limited, Limes-avenue, New Southgate, N., writes us: "At the meeting which was held on Tuesday last, May 2, and at which I presided, it was resolved that the Syndicate be voluntarily wound up, with a view to form a large company to work the process. We found that the capital of the Syndicate was too small, but the process finds support and admiration enough to warrant our bringing it out on a larger scale."

POLARISATION EXPERIMENT.—Mr. J. Cook writes to *Nature* that, by the following simple arrangement, a single pile of glass plates may serve at once as polariser and analyser, and be used to study or to exhibit on a screen the interference colours with mica or crystal sections. It may not be new, but he has not seen it given anywhere. A beam of light is reflected down from a pile, polarised in the plane of reflection. Passing through a double-refracting crystal, it is resolved and then reflected by a common mirror under the crystal. On passing through the pile, which polarises by refraction in a plane at right angles to the plane of first polarisation, it shows the interference colours. Using sunlight, and interposing a convex lens, we may by this simple means project the interference rings of crystal sections.

ADAPTATION OF LEAVES TO THE INTENSITY OF LIGHT.—The term "photometric" is proposed by Professor J. Wiesner for those leaves which assume a definite position in light, either in order to obtain as much illumination as possible, or to screen themselves from too much light, those which do not possess this property being "aphotometric." Photometric leaves, again, may be "euphotometric" or "panphotometric," according as they adapt themselves only to the maximum of diffused light, or to both direct and diffused sunlight. The former are characterised by assuming a fixed position, at right angles to the direction of the strongest diffused light, while the latter have no such fixed position. The vegetation of forests and those plants which grow in deep shade present the most frequent and clearest examples of "euphotometric" leaves.—*Biologisches Centralblatt*, 1899, p. 1.

THE ART STUDENTS' PROTEST.—A meeting of art students, convened by the pupils at Slade School, Gower-street, was held on Saturday, May 6, at 20, Fitzroy-street, to protest against the decorations now being carried out at St. Paul's Cathedral by Sir William Richmond. Not twenty students were present. These came from the Academy, Westminster, South Kensington, Birkbeck, St. Martin's and Slade Schools. Mr. Max West (Secretary) presided. The Chairman said that what was proposed to be done was to form an executive committee, which should draw up a memorial for presentation to the Dean and arrange for a procession or deputation. Several of the students having condemned the scheme of decoration, the Executive Committee was appointed to draw up the protest and arrange other matters. Various schools are represented on the Committee. Novelty was lent to the meeting by a stranger entering the room and protesting against any "Romanising movement." He declared himself a follower of Mr. Kensit, and was hissed for his trouble.

NOTES FROM THE WEST OF SCOTLAND.—What promises to be an important new function in relation to photographic exhibitions in the West of Scotland is announced in connexion with the forthcoming Horticultural Society's Show in St. Andrew's Hall, Glasgow. Photography hitherto at flower shows has been unknown, but this year will see a fine collection of fruit and flower studies on view at this very large and popular Show. A strong and influential committee has been appointed to look after the Photographic Section, and the scheme is evidently being assisted by the West of Scotland Photographic Association, several of the more prominent members of which are on the Committee as well as being Judges.—What must be termed a very bold and striking form of advertisement has been adopted by the enterprising firm of Messrs. Rae Brothers, who some time ago took over the business of the late Mr. James More, the show-window in Renfield-street having been handed over to a local firm of decorators, who have draped the entire framework of the window in a very artistic manner. The Messrs. Rae have made a very striking display of cameras, hundreds of which, in every size and shape and form, are literally crammed into the available space, the result being a sufficiently strong attraction to arrest the attention of large crowds of passers-by. The idea has caught on.—Already the air is full of rumours of various schemes in connexion with the 1901 International Exhibition, in which photography will require to play an important part. Printers and process-block makers are already feeling a distinct improvement in business over this function, and several bold advertising schemes are talked about which will help photography considerably. The whole undertaking will be a very much larger affair than that of eleven years ago, when, on an average, upwards of 100,000 visitors attended the Exhibition daily.

ROYAL INSTITUTION: FORTHCOMING CENTENARY CELEBRATIONS.—The Annual Meeting of the members of the Royal Institution was held on the first inst., the Duke of Northumberland (President) presiding. The annual report of the Committee of Visitors for the year 1898, testifying to the continued prosperity and efficient management of the Institution, was read and adopted, and the report on the Davy-Faraday Research Laboratory was also read. Fifty-eight new members were elected in 1898. Sixty-three lectures and nineteen evening discourses were delivered in 1898. The books and pamphlets presented in 1898 amounted to about 271 volumes, making, with 659 volumes (including periodicals bound) purchased by the managers, a total of 928 volumes added to the library in the year. Thanks were voted to the President, Treasurer, and the Honorary Secretary, to the Committee of Visitors and Managers, and to the professors, for their valuable services to the Institution during the year. The following gentlemen were unanimously elected as officers for the ensuing year:—*President*: The Duke of Northumberland.—*Treasurer*: Sir James Crichton-Browne.—*Secretary*: Sir Frederick Bramwell, Bart.—*Managers*: Sir Frederick Abel, Bart., Sir William Crookes, the Duke of Devonshire, the Right Hon. the Marquis of Salisbury, the Right Hon. the Earl of Halsbury, Dr. W. C. Hood, Professor D. E. Hughes, the Right Hon. Lord Kelvin, G.C.V.O., Messrs. A. B. Kempe and H. Leonard, Sir Andrew Noble, K.C.B., Messrs. A. Siemens, B. W. Smith, W. H. Spottiswoode, and Sir Henry Thompson, Bart.—*Visitors*:

Messrs. W. H. Bennet, A. Blyth, M. Horner, E. Kraftmeier, Lt.-Col. L. W. Longstaff, Messrs. F. McClean, H. F. Makins, L. Mears, Dr. R. Messel, Messrs. L. M. Rate, J. C. Ross, W. J. Russell, A. G. Salamon, Sir James Vaughan, and Mr. J. J. Vesey. His Grace the President announced that in the month of June next the Royal Institution of Great Britain would complete one hundred years of its existence, the first meeting of its members in the building in Albemarle-street having been held on June 5, 1799. The managers had decided that this event, so interesting and memorable in the life of the Institution and in the history of science in this country, should be duly celebrated. They had, therefore, arranged for the delivery of two commemoration lectures. The first of these lectures would be delivered at three o'clock on Tuesday, June 6, by Professor Lord Rayleigh, when His Royal Highness the Prince of Wales, Vice-Patron of the Institution, would preside and receive the Honorary Members; the second of these lectures would be delivered at nine o'clock on Wednesday evening, June 7, by Professor Dewar, when His Grace the Duke of Northumberland (President of the Institution) would preside. It was further announced that the Lord Mayor had, in the kindest manner, consented to give a reception to the members, foreign guests, and representative men at the Mansion House on the evening of June 6.

## Patent News.

THE following applications for Patents were made between April 24 and April 29, 1899:—

CAMERA STANDS.—No. 8519. "Improvements in Supports for Photographic Cameras." W. DEWAR.

FINDERS.—No. 8637. "Improvements in Photographic Finders." W. W. BEASLEY.

PHOTO MECHANICAL PROCESS.—No. 8695. "Improved Photo-mechanical Process for the Production of Finished and Plastic Casts." Complete specification. C. PIETZNER.

SHUTTERS.—No. 8699. "Improvements in Photographic Shutters." A. J. JONES and L. JONES & Co., LTD.

X-RAY APPARATUS.—No. 8934. "Improvements in and relating to Röntgen-ray Apparatus." J. M. DAVIDSON.

ANIMATED PHOTOGRAPHY.—No. 8973. "Improvements in or relating to Animated Photographic Apparatus." T. E. TAYLOR.

LANTERN SCREENS.—No. 9005. "Improvements in Magic-lantern Screens." T. MORTON.

PHOTO-PROCESS PLATES.—No. 9017. "The manufacture of Photo-process Slabs or Blocks." Complete specification. A. SCHÜTTE.

PRINTING APPARATUS.—No. 9058. "Improved Apparatus for Printing from Photographic Negatives." H. L. MOREL.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
13.....	Oldham .....	Excursion: Manchester Cathedral and Chetham's Hospital. Leaders, J. A. and A. Newton.
15.....	Bradford Photo. Society .....	Carbon Printing. F. Cowburn.
15.....	Richmond .....	Annual General Meeting.
15.....	South London .....	Lantern Evening: Prize Slides, 1898.
16.....	Gospel Oak .....	"Cathedral" Hand Camera. Mr. McKellen.
16.....	Hackney .....	Some Recent American Work. Mrs. C. Weed Ward.
16.....	Iale of Thanet .....	Some Bits of Old Thanet. W. H. Hills.
16.....	Leeds Photo. Society .....	Social Evening.
16.....	Royal Photographic Society .....	Specimens of Work with Irregular-grained Screens.
17.....	Croydon Camera Club .....	The Framing and Mounting of Exhibition Prints. Hector Maclean, F.R.P.S., &c.
17.....	Photographic Club .....	Flower Photography. H. T. Malby.
18.....	Hackney .....	Excursion: Hampstead Heath. Leader, W. A. J. Hensler.
18.....	London and Provincial .....	Exhibitions, Technical and Otherwise. R. Child Bayley.
19.....	Croydon Microscopical .....	Prize Slides.
20-22 .....	South London .....	Excursion: Farnham. Leader, F. Goddard.

### ROYAL PHOTOGRAPHIC SOCIETY.

MAY 9,—Ordinary Meeting.—The Right Hon. the Earl of Crawford, K.T., F.R.S. (President), in the chair.

#### BUSINESS.

Two new members were elected and seven candidates for membership were nominated. It was announced that the Mid-Cheshire Society of Art and the Severn and Wye Amateur Photographic Association had been admitted to affiliation.

#### THIN DIAPHRAGMS.

Mr. J. STERRY, referring to the recent demonstration, by Mr. Bolas, of the making of glass diaphragms, thin to Newton's "very black" stage, showed

some varnish films, made by Mr. Glew, exhibiting Newton's rings of colour and also to the black stage. Mr. Glew used very thin celluloid varnish, dissolved in amyl acetate; two or three drops of the varnish were put upon the surface of a saucer of water, and in a few minutes the colours appeared, when the film could be lifted by means of a ring of wire and placed upon any material. Mr. Sterry said the process was very simple, and he had made several of the diaphragms himself; they were very strong, and could be easily handled on the wire; but one could not exactly tell whether the varnish would spread sufficiently, and the colours varied in each diaphragm.

#### PRESENTATION TO MR. CHILD BAYLEY.

The PRESIDENT said that, before the business of the evening was proceeded with, he had to perform the pleasant duty of handing to Mr. R. Child Bayley an illuminated address, signed by a large number of members of the Society, together with a purse, in recognition of the zeal and energy which he had displayed in furtherance of the interests of the Society during his six years' tenure of office as its Assistant Secretary. His Lordship alluded particularly to Mr. Bayley's valuable services in connexion with the Exhibition at the Crystal Palace, and said that the success of that important undertaking was largely due to his untiring efforts.

Mr. CHILD BAYLEY, in acknowledging the presentation, said that the recollection of the kind treatment which he had always received at the hands of the members and official chiefs of the Society would remain with, and be cherished by, him as long as he could remember anything at all.

#### THE PHOTOGRAPHY OF COLOUR.

Mr. E. SANGER SHEPHERD read a paper on "The Photography of Colour," in which he dealt with those branches of the subject having reference to the representation of a coloured object in a monochrome print, and the representation of a coloured object in its natural colours by the three-colour printing process. The paper was an account of the improvements and simplifications which had been introduced with regard to the translation of colour into monochrome, and the triple printing methods, since June last, and the adaptation of those processes to commercial ends. It commenced with a description of Captain Abney's scheme for adjusting colour screens to sensitive plates for representing each colour according to its luminosity, and gave detailed experiments in this direction, the result of which was that a screen had been obtained which, with Cadett's rapid spectrum plates, would exactly represent the colours in any object according to their luminosities. In landscape photography all cloud detail could be secured, and within the range of printing density, but the exposure was increased forty times; the plates referred to, however, were so exceedingly rapid that an exposure of fifteen seconds with *f*-22 in a not very bright light was sufficient for one of the examples shown. A very pale yellow screen, increasing the exposure twice, would largely reduce the action of the blue and ultra-violet, and produce a marked improvement in the rendering of greens and skies in ordinary landscape work. Mr. Shepherd, after referring very fully to this branch of the subject, adverted to the three-colour printing process, the principles of which he explained, and showed some very fine slides by Mr. Saville Kent. He dealt also with the application of Captain Abney's sensitometer to the adjustment of the screens for three-colour work, and with methods and apparatus for the production of blocks for the type-printing press. With regard to the difficulty of ensuring accurate register, he said that a press had recently been invented which would print the three impressions at one operation. The three half-tone blocks were mounted on a revolving cylinder, and inked in turn, the three impressions being made one on top of another on a metal plate, from which all were taken up at once by the paper. The rollers could be adjusted by micrometer screws, so that absolute register was obtained, and, as all the colours were received by the paper in one operation, the difficulties entailed by separate printings were obviated.

Mr. CHAPMAN JONES, Mr. W. E. DEBENHAM, Mr. LOVIBOND, Mr. SAVILLE KENT, and Mr. WARBURG took part in the discussion which ensued, to which Mr. SANGER SHEPHERD replied.

#### COMING EVENTS.

May 16, Photo-mechanical meeting; exhibition of specimens of work with irregular-grained screens. May 23, Technical Meeting. "Korea," by Mrs. Isabella Bishop. June 13, Ordinary Meeting. "Acetylene," by Professor Vivian B. Lewes.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 4.—Mr. Philip Everitt in the chair.

The Chairman passed round one of Thorpe's direct-vision spectroscopes, composed of one prism, upon one end of which was attached a celluloid copy of one of Rowland's gratings, with 14,300 lines to the inch. In such a manner it becomes possible to make a small pocket spectroscope of considerable dispersion, which, for size and efficiency, would compare well with the usual direct-vision spectroscope of three or five prisms.

The HON. SECRETARY read a paper contributed by Mr. W. T. Wilkinson under the title

#### EXPOSURE AND DEVELOPMENT.

The author laid down two important factors in the production of technically perfect negatives, viz., correct exposure and suitable development. By exposing for the shadows and allowing the lights to take care of themselves, and following this with a judiciously mixed developer, it becomes possible to obtain a rendering of the subject true in every respect. To facilitate the estimation of the correct exposure, the possession of an exposure meter was stated to be as much a *sine-quid-non* as was the focussing cloth or the ground glass; but the meter used must be one which requires an actual test of the light at the time of exposing. Exposure tables cannot be of much service, because they do not allow for the ever-changing actinic value of the light. The presumption that at a given time of day in a given month the light may be represented by a certain factor is an unreliable guide, and the author

mentioned an instance in his own experience where the "table" exposure worked out at only one-fifth that indicated by the meter, and another where the error was on the other side. Hap-hazard exposures required the exercise of all the faculties in developing to discover the amount of exposure, whether over or under, whereas, with plates exposed correctly by meter, they may be developed with some degree of certainty of the result. By modifying the pyro-soda developer according to circumstances, the statement of the textbooks that it is the best all-round developer may be true for seventy-five per cent. of subjects, but for the remaining twenty-five per cent. any pyro formula is indisputably bad. For normal exposures and subjects, that is to say, pyro soda may be the best, but for abnormal cases—snap-shots, interiors, &c.—the more modern reducing agents are preferable. Pyro has certain characteristics, and metol, for instance, has others, and by blending the two results may be obtained not otherwise possible. Halation that would appear with pyro would be less conspicuous with metol, or even abolished. Metol-quinol was mentioned as a good developer, but more visual density was necessary than with pyro. In fact, pyro in small traces forms a good addition to either metol or metol-quinol, on account of the slight colouration it induces. Its characteristic colour forms one of the chief reasons why pyro holds its ground against the newer comers.

A discussion ensued as to the use of the actinometer. Opinion was about equally divided for and against those involving the actual test of the light by exposure of paper thereto, and those where the power of light was visually estimated.

The CHAIRMAN was against the test by exposing paper on the ground that the value of the light may alter very appreciably between test and actual exposure of the plate.

Mr. H. C. RAYSON pinned faith to the guidance of such meters, however, and said that surely fluctuations of light value could be allowed for when exposing.

The discussion veered round on to the matter of sulphite in the developer, Mr. TEAPE finding that solutions containing a given quantity of sulphite after a time failed to give the same blackness of image, although the solution had undergone no change in appearance. Sulphite solution, by keeping, gradually lost its power of yielding black deposit with a certain quantity of solution.

**Hackney Photographic Society.**—May 2, Mr. W. Rawlings in the chair.—In the course of the evening a lecture was given by the Rev. F. C. LAMBERT, on the subject of

#### SOME EXPERIMENTS IN OPTICS.

The lecturer said he would start with the assumption that there was some one present quite unacquainted with the subject, and he then showed, by some simple experiments, the main facts of ophthalmics and their relation to photography. He showed how, by means of a candle, lens, and screen, the respective distances of all three were dependent on each other; in other words, their relative distances formed what are known as conjugate foci. The photographic lens resembled the human eye in that only one object could be in focus at the same time, but they differed in the method by which another object was brought into focus. With the photographic lens this was brought about by the alteration of the distance of the object; with the eye, the curvature of the lens itself was altered. Among many other interesting experiments shown was one proving that we see upside down. It consisted in looking through a pinhole in a piece of paper at some bright object, holding at the same time a pin, head upwards, between the eye and the pinhole. The pin then seemed to be upside down. Why? The explanation of this was that, in ordinary vision, the lens of the eye throws an inverted image on to the retina, which we by an unconscious mental action reinvert. In the experiment the pin casts a shadow (not an image) on to the retina right way up, and we see this upside down through the aforesaid involuntary and unconscious habit of inversion. Experiments were also shown to illustrate the effect of irradiation. This occurs when a bright object is seen against a dark background, the result being to make the bright object seem larger than it really is. An example of this is to be seen with the new moon, the thin crescent of bright light seeming to bulge out from the dark disc. Other experiments of important bearing on practical photography were those illustrating the effects of contrasts. Dark objects have the effect of making adjacent light objects seem lighter and *vice versa*. Thus a weak print with a dark mount is made weaker, a dark print with a light mount seems to become darker. Besides the contrast of shades there were also those of lines, many examples being shown of the modifying effects of cross lines and how judgment might be deceived thereby.

**Bath Photographic Society.**—At the last meeting the Hon. Secretary handed round a large number of negatives and prints by processes now obsolete. These were produced in the early fifties by Mr. C. Pooley, and the methods were briefly described by Mr. W. Middleton Ashman as each example was introduced. Three specimens were in excellent condition, showing very little to be desired in point of quality. Among the exhibits was the first photo-lithograph from a process invented by Mr. Pooley, and a portrait etched on glass by the fumes of hydrofluoric acid was also shown. The collection was lent by Mr. Pooley, of Bath, and a vote of thanks was passed to that gentleman for his courtesy in sending the pictures to the meeting.

#### FORTHCOMING EXHIBITION.

1899.

May 12, 13 ..... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### HAND GRENADES AND CINEMATOGRAPHY.

To the EDITORS.

GENTLEMEN,—I hear that in several French provincial towns no cinematograph performances are allowed without the operator being provided with a fire-extinguisher in the form of bottles or grenades, procurable at some central pharmacy, and sealed with the seal of the municipality.

These grenades must be close at hand in a prominent place whilst projecting, and a police officer is bound to enforce the regulation, and seeing to the exhibition being stopped in the absence of the extinguisher.

We all know that these grenades will prevent a fire spreading in nine cases out of ten when applied at its outbreak, and it occurs to me that performers in England will be wise to adopt this cheap and efficacious means of protection against but too frequent accidents.

For those who are not familiar with these extinguishers, already prepared and bottled, I will enumerate those procurable at the large stores: The Imperial hand grenade, Sinclair's new hand fire grenade, the Harden Star grenade, all costing from 2s. to 2s. 6d. a piece; but for economy and facility of carriage sake, when travelling from one place to another, we can carry with us the ingredients in their solid state, making the following solution which is used in Switzerland and the United States and will work well, viz.: An aqueous solution saturated with 3 parts of sea salt, and 4 parts of ammonia hydrochlorate brought to boiling point and then lodged in bottles which, thrown into the fire at its inception, and broken to pieces, will extinguish it at once.

Another solution which I take from the "Enquire within" appears equally good, as it ought to be coming from such a trustworthy source, namely, Take a quarter of a pound of pearlash, dissolve it in hot water, pour it in a bucket of common water and throw into the fire.—I am, yours, &c.,

GEORGE FERNAU.

Bellevue, Montvireon par Sartilly, Manche, France, May 8, 1899.

### A COPYRIGHT DISPUTE.

To the EDITORS.

GENTLEMEN,—My attention has been called to the following in your last issue:—

"COPYRIGHT.—F. T. BLACKBURN says: 'I have taken a photograph of the Salterton Town Band, and the Bandmaster wrote me, giving me permission, on behalf of his men, to copyright same, and your publishers kindly undertook registration for me. I was not paid for photographing them, but have since sold copies to the members of the band. I have every reason to believe that it has been infringed. Have I a clear case?'—In reply: Yes, you have an absolutely clear case, and can impose your own terms."

What does Mr. Blackburn mean by not being paid for photographing our band?

He did it at our request, at his own price, in the usual way of business, viz., that we guaranteed to take not less than eighteen copies, at 2s. each, which he supplied and was paid for. As to the copyright, it was not mentioned when the order was given, but when he brought the proof for our inspection.

Our Bandmaster may have given his written consent, but some of our members are under age, and their parents have never been consulted in the matter.—I am, yours, &c.,

ONE OF THE BAND.

May 6, 1899.

### A SOCIETY FOR PHOTOGRAPHIC PRINTERS.

To the EDITORS.

GENTLEMEN,—With your kind permission I will endeavour to reply to Mr. Willatt. I would say, first, that Mr. Willatt is mistaken in supposing that by organizing the photographic printers alone he would attain conditions similar to those at present existing between the various members of the building trade. He would not, for the simple reason that these desired divisions are a result of the more developed state of that trade, and exist also by mutual agreement.

Allowing the photographic printers organized, they still have no control over the other sections, and consequently the advantages they might derive from organization are inasmuch destroyed. Beyond this, it breaks down that idea of unity amongst the members of the trade which it is the aim of trade unionism to foster—the spirit of common interest, not only between the followers of the same occupation, but also between the whole body of workers productive and distributive.

As regards the photographic printers forming their section, nothing that I know of in the constitution of the National Union of Shop-

Assistants prevents this being done at present. If Mr. Willatt can induce twenty or thirty printers to form a branch, the Secretary would be pleased to give them a start. What, however, would be the practical advantages of having "a union of their own" I do not gather from Mr. Willatt's communications.

In his second paragraph your correspondent attempts to maintain two lines of conduct which are contradictory. He asserts: "There is competition and fighting for berths, and the assistant can't stand out of a berth because he cannot get twenty-five shillings," which is the gospel of "free labour;" he then proceeds to advocate a "photographic printers' union"—a combination which could not possibly recognise the right of a member to work for a 1*l.* weekly when 2*l.* is a fair wage. I faced this difficulty in my last; maintaining that the individual assistant is not free to accept a lower wage than the competition rate, but is compelled to do so by the force of circumstances; that is not freedom, but slavery. To remedy this, it is necessary to organize a powerful combination in order that the assistants may bargain with employers "collectively," and a weak and struggling photographic printers' union is not likely to meet such a demand.

Now, as I have again and again shown, the shop assistants are fighting our battle, and our cause is also their cause. We are at one on—

The abolition of the living-in system.

Reform of the reference system.

Payment for overtime.

Healthy workrooms and shops.

Abolition of fines.

Payment of railway fares by employers, &c.

Why, then, not join in with those who are going in our direction, instead of running a little show "on our own?" Why form a "little rivulet" when we have an opportunity of joining the "great current?"

I am for the "great current," but it is not enough for me to know that I am "bounding on towards the everlasting sea," especially in reference to trade unionism, which is largely a matter of hard finance and business principles. I should have liked to have touched on the *£ s. d.* side of Mr. Willatt's proposal; but, as I have already taken up a considerable portion of your valuable space, I must reserve my remarks until another occasion.—I am, yours, &c.,

JOHN A. RANDALL.

May 7, 1899.

## NORWAY IN JUNE.

To the EDITORS.

GENTLEMEN,—In answer to your correspondent, I should be obliged if you would let me say that as I have been a photographer on a steam yacht sailing from Scotland to Norway during the season of 1897, and also a native of that country, I may be able to give him a few good hints as regards same. In the first place I would advise him to have a few plates taken and developed so that he can see how he goes on. This he can have done on board by the steamer's photographer, and he will also be able to have free use of the dark room for changing plates when not engaged. He should have a good and quick shutter and also plates; as a great number of the views must be taken while the steamer is in motion, I would recommend the Thornton-Pickard double blind shutter as a good one. There will be five or six overland trips, so he will have to be well prepared with plates. Most views should be taken on the trip from Bergen overland and joining the steamer at Gudvangen. He must be careful on this occasion as regards plates, as the finest scenery is near the end of the journey.—The Nærdal Pass. This is a mistake that is often made, and is very disappointing if not prepared for. A few good pictures should be got in the Guranger Fiord, but must be taken while in motion. He will, however, have time to get prepared for this, as the time of passing each place of note will be duly announced on the day's programme. To conclude, a picture should be taken of Tromsø harbour showing the "Midnight Sun."—I am, yours, &c.,

S. SVENDSEN.

55, Conington-road, Morden Hill, Lewisham, S.E., May 8, 1899.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

H. Colebrook, 5 Grosvenor-terrace, Station-road, Sidcup, Kent.—Photograph of a child in basket entitled "Star Fishing."

A. Weber, 11, Knowsley-street, Bolton, Lancs.—Two photographs of the late Rev. Dean O'Brien, of St. Mary's Church, Bolton.

A. J. Ashbolt, 10, Exmoor-road, Southampton.—Two photographs of group of Southampton Football Team, Southern League Champions, 1896-7, 1897-8, 1898-9. 1. In striped shirts; 2. In white shirts.

GWNFA.—In our next.

C. L.—Very good indeed.

PHOTOGRAPHER.—We think you would be justified in refusing payment.

REGISTRATION.—Yes, by forthwith registering the photograph at Stationers' Hall.

W. L. FIELDHOUSE.—Thanks for your note; no further reference to the matter is needed.

T. EVERITT INNES.—We are obliged for the note and drawing, which we will endeavour to use.

LUCIANUS.—We have not seen any reference to such a paper. It is probably a platinum-toned collodio-chloride surface.

GWALLA.—Better select this JOURNAL for the purpose. The cost of such an advertisement is published in each number.

J. MCKISSACK.—Mr. George Bankart, of West Walk, Leicester, would probably give you a few hints on the subject.

XYLONITE.—T. RUSSELL. Xylonite, in the unmanufactured form may, we presume, be had from the British Xylonite Company.

LUMINOSITY.—1. We believe the light can, with care, be used for both kinds of plates. 2. We should wait until development was complete.

W. J. STEARN.—The *Moniteur* is the only one in any way comparable to this JOURNAL for your purpose. Sorry we can offer no further suggestion.

CURIO.—1. If the patent is valid, you can be proceeded against for infringement. 2. Better negotiate with the patentee. 3. No; it would be an infringement.

DISMISSAL.—C. As you only had a verbal agreement, you are, *de facto*, only a weekly servant, and are therefore liable to be, as you have been, dismissed at a week's notice. The case is a hard one, but there is no remedy for it.

OZOTYPE.—S. CLARY. As you have omitted the manganese salt, as given in the formula by Mr. Manly, you cannot say you have given the process a fair trial. The only palpable cause for your failure that we can give is that you have not followed the formula.

SENSITISING BATH FOR CARBON TISSUE. T. BARKER.—A bath of three and a half to four per cent. is quite strong enough for this time of year. In winter five per cent. would be better, and in summer three per cent. would be preferable. The warmer the weather, the weaker should be the solution.

PATENT.—CAUTIOUS. We cannot say if you would be infringing or not. If the patent has been completed, you can see the specification of it at the Patent Office. If it has not been completed, as the provisional protection was granted more than a year ago, there is no patent, and therefore none to be infringed.

STEREOSCOPIC PICTURES.—J. WILSON. The pair of No. 1 B portrait lenses will do quite well for stereoscopic purposes; but, as you cannot get the centres closer together than three and a half inches, they are hardly suited for taking near subjects, as the relief will appear exaggerated in the stereoscope. Probably, however, by taking a piece off each of the flanges, they may be brought closer together.

SCALE ON LENS MOUNT.—C. BREGAR says: "I have just been given an old portrait lens by Voigtlander, and on the mount is engraved a sort of scale. What is the meaning of that, please?"—The lens is evidently one of the old form that has a chemical focus. The scale is to show the difference between the visual and actinic focus, and the necessary alteration to be made after the lens has been focussed.

DETENTION OF SPECIMENS. SEVERAL TIMES FLEECE writes: "I, like many others, have been fleeced out of several lots of specimens sent with applications for employment. In reply to one advertisement, I know two besides myself who sent specimens, as requested, and none of us could get a single one back. Is not this a matter that the Royal Photographic Society should take in hand, for the protection of helpless employees, and for the credit of the profession?"—It is certainly very desirable that something should be done to put a stop to the cruel fraud, but we do not think it is within the province of the Royal Photographic Society to do it.

SOLUTION OF CHLORO-PLATINITE OF POTASSIUM.—E. G. R. says: "I should be glad if you would inform me whether chloro-platinite of potassium can safely be kept dissolved in distilled water, provided it is protected from light. I have been much troubled in the past by the platinum being thrown down, thus rendering the solution useless for toning purposes. I have hitherto made the solution slightly acid with nitric acid. Perhaps that may be the cause of the trouble."—If the solution is made with pure distilled water, and in a perfectly clean bottle, it should keep well. If the solution be acidified at all, hydrochloric acid would be preferable to nitric acid.

PHOTOGRAPHING A SILVER VASE.—H. T. HILLHOUSE says: "Please tell me what to use to cover a silver vase with so that I can photograph it without getting any glare; also can you give me a really good recipe for a backing—to cover the back of a plate to prevent halation when taking interiors?"—The surface of the vase may be dulled by dabbing it over with a lump of common glazier's putty. Another plan is to place a piece of ice inside the vase immediately before exposing; the cold causes moisture to condense on the metal and thus dull its surface. A good receipt for a backing is given on p. 1063 of the ALMANAC. Avery's backing, which may be obtained through all photographic dealers, is also excellent.

## EX CATHEDRA.

OUR reference a fortnight ago to flexoid, a new transparent, flexible support for sensitive emulsions, has brought us a number of requests for fuller particulars of that substance, and we have also been asked to indicate the source whence the new film is to emanate for commercial purposes. The information was given us privately, so that we were unable to answer the questions that were put to us. We may, however, say that we have been promised, in a short while, samples of flexoid suitable for ordinary negative and cinematographic work, so that its commercial introduction may be regarded as imminent.

\* \* \*

WHILE on the subject, we may say that two other substitutes for rollable celluloid film are almost ready to be placed on the market. Hence considerable competition in flexible supports for photographic purposes may shortly be expected. The field available for film photography is an enormously wide one, and, in our opinion, not only will good substitutes for rollable celluloid find ready acceptance at the hands of the public, but celluloid itself will also maintain a great hold for

photographic purposes. At any rate, the conveniences of film photography to vast numbers of photographers are so great, that commercial enterprise in supplying the demand can scarcely meet with an unfavourable response for years to come. At the same time, just as was the case thirteen years ago, when paper negatives were made a great feature of, the consumption of glass plates is still going on unchecked—indeed, their sale all round is on the increase. What more valuable indication could one have of the strong hold on popular favour which photography has undoubtedly secured?

\* \* \*

At that popular place of amusement, the Alhambra in Leicester-square, a distinct hit has been made by M. Rudinoff, a miscellaneous entertainer, who combines the essential qualities of a "screever," a siffleur, and a shadowgraphist. It is true, says a daily contemporary, that the new comer does not work upon pavements with chalks and crayons. He smoke-dries his easel over a gas fire, and by subsequently removing the smoke in patches produces a remarkable study in black and white. Rudinoff is a kind of Whistler—with a difference. It will be obvious from this that M. Rudinoff employs what may rightly be termed a pure carbon process as the basis of his effects. Though having little direct photographic interest, it may be worth while noting that by taking a deposit of fine soot—or carbon—as a ground, and putting in the lights in the manner above indicated, most charming effects are obtained skilled hands. It is a carbon process which relies for success absolutely on the element of "personal control."

\* \* \*

ELSEWHERE in the JOURNAL this week we reprint a paper, read before the Edinburgh Photographic Society by Mr. A. F. Hargreaves, on a photographic printing process in a new permanent colour. Although the author does not enter into the details of his process, it appears that his results are produced on bleached cotton cloth, the colour being absolutely fixed in the cotton filament by the initial application thereto of a mordant and subsequent treatment with another constituent which forms a lake or pigment. We await details of the process with much interest; in the mean time, by the courtesy of our friend, Mr. J. M. Turnbull of Edinburgh, we have had the opportunity of inspecting specimen prints. These may be best described

as of a rich purple colour, and, the surface being bleached cotton cloth, it may be understood that considerable breadth of effect is obtained.

\* \* \*

ACCORDING to the May number of the *Photo-Miniature*, which contains an admirable illustrated article on "The Pose in Portraiture," well worth perusing by professional photographers, Mr. Walter E. Woodbury, who for the past five years has edited the *Photographic Times*, has now joined the Nepera Chemical Company, and will be in charge of the publicity department. The *Photographic Times* will be continued by the same staff who have assisted in the past. The guidance and experience of Mr. W. I. Lincoln Adams will, doubtless, aid from time to time.

\* \* \*

WE have received the ninth report of the Committee on Photographs of Geological Interest in the United Kingdom, from which we take the following extracts: "During the year 250 new photographs have been received, bringing the total number in the collection up to 2001. In addition to this, 44 prints and 14 slides have been given to the duplicate collection, which now contains many representative photographs, so that future additions are likely not to be so numerous, and to consist only of exceptionally good examples of geological phenomena. Northampton is now represented for the first time in the collection, and the following counties and districts are more richly represented than hitherto: Gloucester, Norfolk, Warwick, Westmoreland, Worcester, the Isle of Man, Aberdeen, Ayr, Bute, Banff, Fife, Inverness, and Sutherland. The most important event of the year, from a photographic point of view, is the inauguration of the National Photographic Record Association, under the presidency of Sir J. B. Stone, M.P. The work of this Association is distinct from that of this Committee, as it is mainly limited to *records*, while the Committee aim at securing *typical phenomena* as well as records. The Committee will furnish to the Association each year a list of the photographs of which the Association ought, where possible, to secure duplicates. The Secretary has been elected a member of Council of the Association." Accompanying the report is a circular giving information relative to the collection of geological photographs, and hints as to the selection of a suitable camera for geological field work. This is obtainable of the Secretary of the Committee, Mr. W. W. Watts, Mason University College, Birmingham.

\* \* \*

MR. R. W. CRAIGIE, Hon. Secretary of the Photographic Salon, asks us to announce that the Annual Exhibition of the Photographic Salon will be held at the Dudley Gallery, Piccadilly, for about the usual period, during the months of September and October next. The prospectus and entry form will be issued shortly.

\* \* \*

At the next meeting of the Royal Photographic Society, on Tuesday, May 23, at 8 p.m., at 12, Hanover-square, London, Mrs. Isabella Bishop, F.R.G.S., will deliver a lecture on "Cores," illustrated by photographic lantern slides. We are asked to state that the Society will be glad to see anybody interested in the subject, and that tickets may be obtained on application to the Assistant Secretary.

MESSRS. R. W. THOMAS & CO., of Thornton Heath, write us: "In your issue of May 12, we read that Messrs. R. W. Thomas & Co. were represented at the annual dinner of the Association of Plate and Paper-manufacturers—this of, course is, an error, as our Company retired from the Association in October 1897. If you will kindly insert this, it may save the Association's Secretary and ourselves from unnecessary correspondence." We are sorry for the unintentional inclusion of Messrs. Thomas's name in the list given.

\* \* \*

OWING to pressure on our space this week, we are compelled to hold over several articles including the second on the subject of Colour Facts and Fallacies.

### SULPHITE AND METABISULPHITE.

THE history of the use of an alkaline sulphite as an addition to the pyro developer is replete with contradictions. When its merits were first pointed out by the late Mr. Herbert Berkeley it fell absolutely flat, and it was not till more than a year had elapsed, and after writers in this JOURNAL had pointed out the great advantages gained from its use, that it began to be tried in real earnest by the body of workers. But, all through, a kind of crass fatality attended it. Photographers as a rule would not understand its true functions; they persisted in regarding it as an agent for preserving solutions of pyro from discolouring. This, as we have more than once emphatically pointed out, is a mere subsidiary quality. If that were its only use, there need be no employment of the sulphite, for the addition of a sufficiency of almost any acid would answer all practical purposes in that direction. Its real usefulness lies in preventing or reducing staining of the negative primarily, and of the fingers in a lesser degree. All negatives taken before its introduction were of a terribly yellow colour. We are aware that many photographers affect a preference for yellow negatives, but not such a colour as is obtained when no sulphite whatever is used.

Not content with this ignoring the true function of the salt, a further nebulousness was imparted to the already hazy appreciation of its value by the introduction of a salt, the metabisulphite of potassium, which is commonly listed at a price sixfold that of the sulphite, and which has not one iota of advantage over the less expensive material. We may be told that the metabisulphite is a better preservative than the simple sulphite, but it is not so if the latter be considered from that point of view alone, for by the addition of an acid—citric, sulphuric, &c.—the keeping properties become in every way equal, and, as we say, at a sixth of the cost. Yet the use of the dearer salt is increasing, and in the published formula for a one-solution developer we even actually see it set down, although it is patent to the most casual observer that, when the alkali, carbonate, or caustic, is added, there is actually no difference, chemically, between the resulting compound and one with metabisulphite. One cardinal point to see to in the course of any chemical operation—and such, of course, is the act of development—is that perfect uniformity from day to day is carried out. But how can this be with the employment of the meta salt? Few photographers who mix their own chemicals care to be always weighing their salts; they prefer to have them in solution. But metabisulphite is continually giving off sulphurous acid, even in the crystalline form, while,

if it be kept in solution, the change is more rapid. Hence it is an uncertain quantity when used in the developer, and absolute uniformity, which is so desirable, cannot obtain with its use. It would be no argument to say that, although the meta salt is a dearer one, its cost is neutralised by the smaller quantity used, for it is purely a question of the amount of acid added to the ordinary kind; an ounce of metabisulphite has not any more action in preventing the negative from staining than has an ounce of the neutral salt.

There is one other strange misconception with regard to the standard sulphite, and that is the strength at which stock solutions of it are to be mixed. We have seen recommended all proportions, from twenty to forty per cent. strength; but we unhesitatingly say that in this country no stronger a solution than twenty per cent. should be stored. It is quite true that a twenty-five per cent. can readily be made, but, when the temperature of the solution is reduced to near the freezing point of water, a portion of the salt will crystallise out. Besides, for lovers of the metrical system, twenty is a far better proportion than twenty-five, for it is just double a ten per cent. strength, which is a decimal division dear to the honest heart of the worshipper of the metrical system—a system by no means in general use in the country of its invention, France. We trust that what we have written will be instrumental in bringing into its proper position the value of neutral sulphite of soda and the comparative worthlessness of its supplanter, the metabisulphite of potassium.

**The Lime Light in the Church.**—The Rev. W. Carlile, at St. Mary-at-Hill Church, was the first, we believe, to introduce, some years ago, the lantern into the Church; and it has proved an attraction to the evening services. The subject chosen for last Sunday evening was entitled, "Eighteen pints of beer a day." From six to seven there was a sacred concert with a full band. The Rev. Mr. Carlile is to be commended for his work in this direction. It is noteworthy, however, that the London County Council prohibit this sort of thing, in places of public entertainment under their control, on Sunday evenings. Why?

**Explosion of Chlorate of Potash.**—Photographers and lanternists are not, nowadays, much concerned about chlorate of potash, as they usually obtain their oxygen ready-made, compressed in cylinders. Accidents occasionally happened when they had to generate it themselves from the chlorate, but then they were always attributable to some extraneous matter present, and not to the chlorate itself, which is not, *per se*, explosive. In the recent catastrophe at St. Helens the accident did not arise from handling or dealing with the chlorate, but from a fire in an adjoining building; but why did it explode and produce such devastation? Various theories have been suggested, one of which is that the heat from the fire that preceded the explosion might have caused the formation of distillation products from the timber which, mixing with the chlorate dust, might cause a highly explosive mixture, &c. At the inquest, which at the time of writing has not been held, expert evidence will be called to account for the explosion, and the result will be looked forward to with interest by all who have still to do with chlorate of potash for the production of oxygen.

**A New Explosive (?)**—What one sees occasionally in the lay press is often highly amusing. In a paragraph now before us—in the *People of Sunday* last—it is stated that; "a miner named Waycott, at Crayhead Colliery, Durham, was drying gelatine before his kitchen fire, when it exploded, blowing a portion of his house down." It is the first time we have heard of *gelatine* being explosive. If it is, the dry-plate makers and the manufacturers of P.O.P. should

be careful in future how they handle such a dangerous material; also we should advise them to keep the knowledge of the fact that it is dangerous from the different insurance companies, or they may find their premiums materially raised.

**Fluctuation in the Value of Paintings.**—At Christie's sale rooms, on Saturday last, a *Holy Family*, by Rubens, was sold for 8300 guineas, and another painting by the same artist was sold to the same purchaser (Agnew) for 1950 guineas. This latter work, in 1806, was purchased for 4000 guineas, and a few years ago it was again sold at Christie's for 3800 guineas, and on Saturday it only fetched 1950 guineas—a great depreciation in market value.

**The "Decorations" in St. Paul's.**—Last week we alluded to a protest by art students against the decorations now going on in St. Paul's. Now a memorial from architects has been presented to the Dean and Chapter, protesting against the continuation of the work of decoration until full opportunity has been given for the consideration of the whole scheme by the best expert opinion available. It is to be hoped that this will be done by the Dean and Chapter—and the "Committee of Taste." A memorial from a body of architects, who are naturally proud of Wren's work, should have great weight—much greater than the protests of artists and art students. Wren's masterpiece is at present—or as it left his hands—a thing of beauty. What it may be when the embellishments—if they are carried out—are finished remains to be seen. While on the subject of St. Paul's, we may again remind our readers that the opportunity still remains for them to secure photographs of the Cathedral from Cheapside, which will be impossible in a very short time hence.

#### SILVER SUB-BROMIDE, THE LATENT IMAGE, AND NASCENT SILVER.

[Translated from the *Photographische Correspondenz*.]

PROFESSOR DR. RICH. ABEGG makes the following statement in the *Archiv für Wissenschaftliche Photographie* (vol. i. p. 15): "We find, without exception, in text-books of photography the view expressed that the substance produced by the direct action of light upon silver haloid is a silver sub-haloid. It is difficult to ascertain, in the present condition of photographic literature, who originated this theory, and upon what grounds it was based. We also find the same theory adopted in Eder's *Ausführliches Handbuch* (vol. ii. p. 28, 2nd ed., 1895), and its harmony with our experience is demonstrated. The theory that the substance of the latent image consists of metallic silver is likewise mentioned in the same work, but it is dismissed as unsatisfactory, without advancing any facts in opposition."\*

Professor Abegg then proceeds to remark that the only reaction which is in favour of the silver sub-haloid theory and opposed to the presence of free silver is the indifference of the latent photographic image to nitric acid, which silver sub-bromide will withstand, whilst metallic silver will not.

Upon the basis of an experiment with *gelatino-bromide* plates, Abegg infers that the latent image is destroyed by nitric acid. He advances this experiment as proof of the nascent silver theory (*silberkeimtheorie*)† and infers that metallic silver is immediately formed by exposure to light, and not silver sub-bromide. This metallic silver is supposed to act as a germ in presence of silver bromide and a developer, and effects the reduction of the silver bromide as more or less copious deposits in forming the photographic negative.

The old controversy of the photo-chemist is thus unrolled, whether the image formed by the action of light upon a silver haloid is metallic silver or a sub-haloid. As mentioned in my *Ausführliches Handbuch der Photographie* (vol. ii., 2nd ed., p. 110), the originator of the former theory was Arago (1839), whilst my researches show Choiselat and Batel were the first to maintain (in 1843) that sub-iodide AgI<sub>2</sub> was formed (*Ausführliches Handbuch der Photographie*, vol. ii. p. 111). The statements I have quoted are the oldest I could find in reference to this matter.

Leaving the historical side of the question, I will now refer to the

\* See THE BRITISH JOURNAL OF PHOTOGRAPHY, March 31, 1899.

† Ibid., March 31, 1899, p. 197.

experiments. Strictly speaking, Professor Abegg confines himself to one experiment only, according to the quotation I have made, and upon the strength of this he rejects the sub-bromide theory of the formation of the latent image. This is the action of dilute nitric acid upon the latent silver-bromide image. If the treatment of the latent image with dilute nitric acid destroys capacity for development, according to Abegg's proof the image should consist of metallic silver, because silver sub-bromide withstands the action of nitric acid.

Professor Abegg made this experiment in the following manner: He dipped an exposed gelatino-bromide plate in dilute nitric acid (1 in 15), and he states that the capacity for development of the light impression was almost destroyed; "not completely," adds Dr. Abegg, "because the gelatine protects the silver, and the acid must be very dilute (1 in 15) for preservation of the film."

According to Professor Abegg's own statement the experiment was not completely successful, as there remained, at least partially, a developable latent image, which had resisted the destructive action of the nitric acid. Such an experiment appears to me an unsuitable basis upon which to decide an important photo-chemical question.

In order to decide the question it was therefore necessary to carry out experiments for the destruction of the latent image by means of nitric acid, under much more stringent conditions. If destruction were possible under such conditions,\* doubtless the silver sub-bromide theory would sustain a heavy blow, but, in the contrary case, the sub-bromide theory would derive very important confirmation.

For my series of experiments I selected collodio-bromide films, because these would not be affected by nitric acid of greater strength. In order to ensure direct contact of the silver particles with the nitric acid in their process of formation, bromide of cadmium collodion† was coated upon glass, and the proportion of nitric acid mentioned by Professor Abegg was added to the silver bath. The bath was composed as follows:—

Water .....	300 c. c.
Nitrate of silver .....	60 grammes.
Concentrated nitric acid ( $d=1.35$ ) .....	20 c. c.

Exposure was made with a Euryscope f.6, at full aperture, from 1 to 4 minutes, at 8 to 4.30 p.m., on March 27, in the studio. The light was good, and the subject black-and-white print. Development was effected with alkaline glycin, after excess of silver nitrate had been carefully removed by washing. An excellent, vigorous negative was obtained, and the presence of dilute nitric acid (1 in 15) had not therefore destroyed the latent image.

Successive additions of 60 c. c., 150 c. c., 300 c. c., and even 500 c. c. of concentrated nitric acid ( $d=1.35$ ), were then made to the silver bath. The plates were sensitized and exposed while saturated with these successive acid solutions, but still an image was invariably obtained, although of thinner character.

I also tried to develop the latent image upon these silver bromide films by means of sulphate of iron (as in the wet-collodion process), but as a precaution it was necessary that the enormously acid silver bath should be first rinsed off with a slightly acid one before applying the sulphate of iron developer. An undoubtedly clear, distinct negative was also apparent after development by this process.

It is therefore proved beyond doubt that dilute nitric acid does not destroy the latent image formed in bromide of silver.

If one remembers that the quantity of nitric acid was increased in the course of these experiments until the bath contained more concentrated nitric acid than water (5 parts of nitric acid to 3 parts of water), the immense stability of the substance of which the latent image is formed in the silver bromide is most surprising.

The nitric acid was of such strength in the last experiment that a physically developed image of metallic silver, after being duly fixed and finished, was completely dissolved by the bath in 30 to 60 seconds. It is thus proved that such strong acid solutions dissolve metallic silver, that metallic silver as such cannot exist in them, and likewise that metallic silver cannot be formed in the camera during exposure.

Whatever may be the substance of which the developable latent image

\* According to H. W. Vogel, bromide of silver, blackened by light, is insoluble in nitric acid, but Carey Lea says an appreciable quantity is dissolved. But the discolouration of silver bromide by light is unaffected by nitric acid, consequently sub-bromide is present (Eder). I described the behaviour of silver sub-bromide in these words in *Fehling's Handwörterbuch der Chemie* (1886, vol. iv., p. 113), likewise in my *Ausführliches Handbuch der Photographie* (2nd ed., vol. i. part 1, p. 177).

† Six grammes of bromide of cadmium were dissolved in 70 c. c. of alcohol and added to 100 c. c. of a 2½ per cent. plain collodion. (*Eder's Ausführliches Handbuch der Photographie*, 2nd ed., vol. ii. p. 457.)

is composed, when a film of bromide of silver receives brief exposure to light, it is quite certain that it cannot be metallic silver.

Upon the ground of these indisputable experimental facts, I consider Abegg's opinion "that nascent silver is formed by the direct action of light" untenable; moreover, that the theory of the formation of sub-bromide in the latent image has been greatly strengthened. In conclusion, I may remark that the phenomena of solarisation are easily explained by the sub-bromide theory, and that they cannot be brought into harmony with the idea of the direct formation of germs of metallic silver, which are scarcely accessible to processes of oxidation.

To prevent false impressions, I wish to add that, according to my opinion, the latent image consists of sub-bromide, which is reduced to metallic silver by the developer more easily than unexposed silver bromide. The metallic silver formed during development may then have a secondary action by electro-chemical processes upon the silver bromide, and intensify the negative, as described by me several years ago, and as Dr. G. Bredig has shown (*Eder's Jahrbuch für Photographie*, 1899, p. 357).

But the primary latent photographic image must be taken as formed of silver sub-haloid in the present aspect of the question.

DR. J. M. EDER.

#### TAILORING AT THE ROYAL ACADEMY.

SOME of the R.A.'s and other portrait painters seem to have given dire offence to the tailors by the way they have rendered the garments of their sitters, and our contemporary, the *Tailor and Cutter*, is very severe upon them in the matter. It complains that there is a disregard to seams, irregularly placed buttons, and the use of ornamentation which is altogether grotesque. Several instances are cited in which the Sartors have been outraged. One is the portrait of a gentleman in a black morning coat with flat braid edges, the sleeves of which are too large, and have the appearance of being bound round the bottom, suggestive of the finish of the good housewife who repairs the worn-out cuffs of her husband's coat—good housewife, too, say we. Another example is of a coat which shows but one buttonhole, and that is on the wrong side. In another case it is a double-breasted frock coat, the sleeves of which are too short, and the collar is compared as being more like a horse collar than that of a gentleman's coat. Lord Kelvin's attire is much complained of. It is a morning coat, but one button is described as looking as if it had once been on a heavy overcoat. The breast pocket, too, is placed too low, and the vest is too short, also the watch-chain is on the wrong side. Fault is also found with his lordship's trousers, as they are innocent of seams or any mode of fastening, and the suggestion is made that he must have grown in them. In another portrait our contemporary says the coat is innocent of buttons or buttonholes, and adds that the silk facings are not a true representation of what is being worn. The costume of the Right Hon. Gerald Balfour also comes in for severe criticism. The *Tailor and Cutter* is evidently grieved about these *lâches* on the part of artists, and "is sorry to think that any of these portraits are to be handed down to posterity as a representation of nineteenth-century tailoring skill."

It has frequently been said that a large proportion of the portraits exhibited at the Royal Academy are painted from photographs. If any of those alluded to were, it is pretty clear that the artists have not slavishly followed the details of the photograph as regards the dress, or, it may be those that are actually worn by the gentleman portrayed not in accordance with the prevailing ideas of our contemporary as to what should be worn. Different gentlemen have different ideas as to the style of garments they wear, and how they shall be made for comfort. Possibly that may account for something, so that, after all, the artists may not be so much at fault. Men were not made for tailors, neither were artists. So much the better perhaps, for the comfort of both in their garments.

#### THE USE OF HYDROGEN PEROXIDE IN PHOTOGRAPHY.

IN the current number of *Photographische Correspondenz*, Dr. M. Andersen contributes a paper on the above subject, in the course of which he says that in 1891\* he pointed out a certain similarity of constitution in some of the simplest of the organic developers, such as hydroquinone, para-amidophenol and paraphenylene-diamine on the one side, and the compounds, hydrogen peroxide, hydroxylamine, and diamine on the other. A comparison of the formulæ will show this at once.

\* *Photographische Mittheilungen* (1891), p. 296. *Eder's Jahrbuch* (1893), p. 421.

With the exception of hydrogen peroxide, these compounds are known to be developers in alkaline solution, and with respect to this he stated that, on account of its peculiar double nature, sometimes oxidising and sometimes reducing, he had tried it as a developer as well as a reducer.

He has now made further experiments, and is able to confirm his statement, and has proved that when alkaline it acts as a developer, when acid as a reducer.

His first experiments when using it as a developer gave no results, because he did not use enough alkali. His first experiment was made with 0.5 gramme caustic soda,  $\text{NaHO}$ , to 100 c. c. of three per cent. hydroxyl. When, however, the quantity of soda was increased to 7 grammes to 100 c. c. three per cent. solution hydroxyl, a bromide plate, showing normally 19-20° Scheiner, gave in this developer, in from five to ten minutes, 12° Scheiner without fog.

The formation of the image is accompanied by the evolution of oxygen, which causes blisters in the film, and this makes the practical use of hydroxyl as a developer very doubtful. Gelatino-chloride plates can also be developed with this, although there was a great tendency to general fog, but potassium bromide acted very powerfully against this, and lessened considerably also the tendency to blistering.

The best formula for chloride plates is:—

Hydroxyl solution (three per cent.)	100 c. c.
Caustic soda	2.4 grammes.
Potassium bromide solution (ten per cent.)	3 drops.

A chloride plate exposed 30 cm. from 3 cm. of magnesium wire under a normal negative gave a vigorous and clear image.

In order to determine what part hydroxyl plays in the development of the latent image, it must not be forgotten that hydroxyl sometimes exerts a strong reducing action, and it will instantly reduce silver, mercury, and gold oxides completely to the metal, and for every molecule of hydroxyl one molecule of oxygen is set free, half of which is derived from the reduced oxide and half from the hydroxyl.

Bromide and chloride of silver emulsified and ripened in gelatine is only reduced, after exposure, by a considerable quantity of caustic alkali; this leads to the assumption that, when one or two molecules of caustic soda are added to a three per cent. solution of hydroxyl, there is, partially at any rate, a formation of sodium peroxide  $\text{Na}_2\text{O}_2$ , and that by this the development is effected. A direct experiment with sodium peroxide confirms the correctness of this conclusion. A solution of

Water	100 c. c.
Sodium peroxide	7 grammes,
Ten per cent. potash bromide	8 drops,

gave on gelatino-chloride silver with normal exposure a clear, vigorous, and well-modelled positive, the film of which was studded with oxygen bubbles.

If we assume that, on exposure of chloride or bromide of silver, a sub-chloride or sub-bromide is formed, the reduction by hydroxyl or sodium peroxide may be expressed by the following equation:—

It is, however, also possible that the sub-haloid is first again oxidised, and that the deposition of the silver takes place in a secondary phase as follows:—

The sodium peroxide,  $\text{Na}_2\text{O}_2$ , stands in the same relation to hydroxyl,  $\text{H}_2\text{O}_2$ , as the phenolate,  $\text{C}_6\text{H}_5\text{ONa}$ , does to hydroquinone,  $\text{C}_6\text{H}_4(\text{OH})_2$ .

In a similar way as one considers hydroquinone as the fundamental

developer, so ought hydroxyl, and not the sodium peroxide, to be considered the developer.

At the beginning of 1898 Andresen had proved that hydroxyl in the presence of hydrochloric acid acted as a reducer. When, in the following summer, MM. Lumière made known the interesting action of ammonium persulphate, he again took up the experiments, and proved that there was a certain similarity between the two compounds as regards the attacking of the densest parts of the image.

Liesegang, in 1898,\* had pointed out that negatives treated with ammonium persulphate could, by immersion in lukewarm water, be converted into a relief image. The formation of this relief also results from the action of acidulated hydroxyl solution without the use of the hot water, as the silver and the gelatine in which it is imbedded is removed. If a silver image—for instance, a very hard negative—is immersed in a solution of—

Hydroxyl (three per cent.)	100 c. c.
Hydrochloric acid (sp. gr. 1.19)	2 „

it will be seen that, especially at a temperature of between 15° and 20° C., the densest portions of the image, after a few minutes, will begin to get loose, and that the silver and the whole of the gelatine surrounding it will dissolve away. If the action is allowed to continue, it extends to the half-tones and then into the shadows. Andresen has not determined whether the silver separates out as such or in an oxidised form, but its colour alters but slightly, if at all.

The reason why the gelatine surrounding the particles of silver loses its coherence easier after treatment with the hydroxyl than that where no silver is might be explained by assuming that the former, by exposure in the camera, &c., has become partially oxidised by the absorption of bromine or chlorine, and for this reason withstands less easily the action of so energetic an oxidising substance like hydroxyl than the gelatine which is left intact during exposure.

The formation of the relief thus produced by hydroxyl ought to be useful for certain photo-mechanical processes.

#### THE RESEARCHES OF EDMOND BECQUEREL ON DIRECT HELIOCHROMY.\*

“It is very remarkable that the impressionable substance of which we speak is sensitive between the same limits of refrangibility as the retina, it is the only one which is shown under these conditions. If the solar spectrum is projected upon a plate prepared as above, the action begins to manifest itself in the yellow and the green, then it takes place on one side towards the red, and on the other towards the violet. The action is stronger where the maximum of light is found. In the red part the substance takes a red tint; in the yellow part, a yellow tint; in the green part, a green shade. The blues are very fine, and the violet tint resembles that of the spectrum.

“If a bundle of luminous red rays is isolated and made to act upon the substance, when it begins to exert its action the colour of the part acted upon turns to red; if the action continues, the tint remains the same; if the experiment is much prolonged, the substance can be completely changed, and there only remains the metallic silver there where the light has fallen.

“If a bundle of blue rays is used, the same effect is produced, the blue tint obtained upon the surface takes more and more strength, and, upon letting the light act during a long time, at the end the tint becomes that of metallic silver. It is still the same for each group of rays, which give, after an action of a certain length, a tint of the same shade as themselves; but it happens finally, if the reaction is nearly complete, that the impressionable substance tends to show metallic silver.

“These effects show that it is not by an action of the kind which gives place to the phenomena of thin layers that the substance reproduces the coloured impression of light, but on account of a special action, which causes the curious substance above named to have the faculty of only diffusing rays of the same refrangibility as those which have acted chemically upon it.

“It is necessary, above all, to give some indications as to its probable composition; although it cannot exactly be told, it is probable that the substance is violet sub-chloride of silver, that is to say, a chloride of silver having an equivalent of chlorine less than that of white chloride.

“By this hypothesis the fact can be cited, that in treating the chloride by the solvents of white chloride, such as ammonia, hyposulphite of soda, &c., the white chloride dissolves and the metallic silver always remains.

\* Concluded from page 294.

"The sub-chloride of silver is the only chemically impressionable substance, which has the remarkable property of reproducing the shades of luminous actine rays. The iodides, bromides, &c., do not give any colour, and, if even the chloride is mixed with a little of these compounds, all shades disappear. The colours are obtained directly by the luminous action, and without the use of any reagent.

"This composition has been tried upon paper, glass, porcelain, collodion, gelatine, &c., but the effect has been more difficult to obtain and less fine than upon metallic plates.

"The influence of the impressionable layer upon the effects obtained is enormous; when the layer is thin, the sensitiveness is great enough. It is much less than the sensitiveness of sheets which are prepared with the iodide of silver than with bromide, to obtain a picture in the dark room, but it is almost as much as the plate iodised in the manner of Daguerre; but, if the sensitiveness of a thin layer is great enough, the effects of colouration are very weak. In using a thicker layer the substance becomes less sensitive and the colours reproduced become clearer; in proportion as the layer thickens, the sensitiveness lessens more and more, but the coloured reproductions are more beautiful.

"There is a certain means of knowing the relative thickness of the layer of sensitive chloride, and which allows it always to be put in the same condition of preparation; it consists in introducing into the voltaic circuit, formed of the battery of the plate and of the bath of hydrochloric acid, an apparatus to decompose water, in order that the electric current which brings the chloride upon the surface of the silver should decompose the water in the second apparatus. The electrochemical decompositions always taking place in definite proportions, it deposits the same quantity of chloride upon the silver plate which it takes from the hydrogen in the apparatus to decompose water; thus, supposing that the electrometer indicates 5, 6, or 7 c. e. of hydrogen, it is certain that there will be as many c. e. of chloride fixed upon the surface of the silver.

"Working in this manner, it can be told at any moment, whilst the sensitive layer is preparing, what is the exact quantity of chloride which is put on the surface of the plate.

"I have discovered that, in order to arrive at a layer of which the thickness should correspond to the *third order of thin plates*, 3 c. e. of chloride per square decimetre are required, the condition then is such that you have sufficiently good reproductions of prismatic coloured images; if it is increased to 6 or 7 c. e. per square decimetre, that is to say, to the thickness which corresponds to thin plates of the fourth order, then you have the best-coloured reproductions; when very good effects are desired, it should stop there. To give an idea of the real thickness of the layer, I should say that, with 4 c. e. of chloride per square decimetre, the layer is nearly  $\frac{1}{1000}$  of a millimetre in thickness.

"When the luminous spectrum is projected upon a surface of silver prepared with 6 to 7 c. e. of chloride per square decimetre, which surface has a shade of almost wood colour, one can see according to the proofs placed before the Society, what are the effects obtained; the part struck by the prismatic red is red, and turns to very dark red towards the least refrangible end; the yellow is hardly visible; the green is well seen, the blue and the violet are superb, and show the same tints as those of the spectrum.

"Altogether the tints, though like those of the luminous actinic spectrum, are a little dark in comparison with the background of the plate, which remains a little clearer.

"But, as will be seen afterwards, the surface can be modified after it is taken from the bath and before its impression by the spectrum, so that the colours obtained are much more beautiful.

"In fact, this substance, which may be called *mineral retina*, can undergo remarkable modifications either from the action of heat or from that of certain parts of light. In raising the temperature of the chloride, but not so high that it becomes fused, towards 150 or 200 degrees, it is found that the tint takes a rosy colour after cooling.

"If the spectrum is made to act upon the substance thus modified, the effects are quite different from what they were before; the limits of action are nearly the same as before, that is to say, are those of the visible spectrum, only the yellow and the green, although pale, show clearly on the background, which remains much darker, and, if the action of the spectrum is carried too far, the final result would be a white trace instead of a grey trace which had been before the heating. If the plates are heated thus above 150°, the physical transformation of the substance which takes place makes most of the tints disappear; but, if it is limited to a slight and prolonged heating, it is not the same; to this effect the sheet is placed in a copper box, which is placed in a stove heated to 30 or 35° at most, and the temperature is prolonged during

four, five, or six days. Then the coloured prismatic impressions are very beautiful, as you will judge. Not only do the different red, yellow, green, blue, and violet tints, placed when the rays from the spectrum of the same colour have acted, appear clearly upon the background, which remains darker, but, again, a bundle of white light acts in giving a white tint to the place upon which it acts.

"The sub-chloride of silver undergoes equally, from the extreme red rays of the solar spectrum, a physical modification as remarkable as by the action of heat, and by another means produces beautifully coloured reproductions of the solar spectrum. To obtain this result, place in a plate-holder, covered with dark red glass (coloured by the protoxide of copper), a prepared plate as it comes from the bath after the action of electricity, and expose the whole to the solar rays. At the end of fifteen to thirty minutes the plate becomes darker than before, and the same effect is produced, which is shown at the least refrangible end of the spectrum. At the same time that this colouring takes place the sensitive substance is modified little by little, and probably in the same manner as under the action of heat. On projecting upon its surface a solar spectrum, it appears at the end of some minutes with all its shades admirably reproduced, and even the yellow and green parts, which before this operation had been dark and slightly indicated, are very clear. The preliminary action of the red rays should not be too prolonged, for the substance becomes less sensitive. These different actions can be judged by the specimens submitted to the Society.

"The coloured impressions once obtained can only be preserved in darkness, but then they can be preserved so indefinitely; if they are exposed to diffused or solar light, they fade little by little and disappear.

"It is very remarkable that it is only in, so to speak, a state of passage that the sensitive substance has the power of reproducing the tints of the actine luminous rays; thus, in leaving the same physical state, that of the unaltered substance and in going towards the extreme limit, which is complete decomposition, the substance shows different physical arrangements, according as it has been struck by such or such a ray.

"It results from what has been said that the coloured impressions that have been shown alter continually, even whilst we look at them; if they are kept in the dark, they do not alter; only, if the substance is not very sensitive, and it is a question of lamp light, the proofs can be left under their influence several days without disappearing.

"The effect that diffused light produces is such that, if a coloured proof is placed under a blue glass, for example, it would take a blue tint and would in time become grey; it would be the same with different coloured glasses, the final state, as to colouration, would seem to be the same whatever the light may be which attacks this substance; it seems, then, that it is only in an intermediate state, and thus, as I have always said, that colourations are shown.

"It is possible to obtain reproductions of coloured images, that is to say, paintings by light, as can be seen by the specimens which I give, of which some are forty years old; but there are reasons which prevent these paintings from being comparatively as clear and having the tints as bright as those of the luminous spectrum. In fact, in the images the compound tints are more or less mixed with white; it is then necessary that the action of the white light should not change the tint of the coloured rays of the predominating tint. To obtain this result, the prepared plates must be first submitted to heat or to the action of red glasses, and then the light ones are obtained clearly, but the yellow and green tints are not clear. If the plates are not heated, the tints appear but the whites are grey. On the other hand, the substance is very slightly sensitive, and it takes several hours, and even several days, to obtain these images. Nevertheless, with precautions these drawbacks may be in part avoided.

"The proofs of the reproduction of coloured images which are here shown are what can be actually obtained by the help of this sensitive substance.

"These last reproductions have hitherto only slightly occupied me to this time, for they have only had for me a purely scientific interest, and I have not thought of applying them, since the impressions only lasted in darkness, and faded little by little in light. All the attempts made up to this time to prevent this fading have not succeeded, and it is only in a transition state that the sensitive substance, the true mineral retina, possesses the remarkable property of preserving the impressions of the actine luminous rays.

"I ought even to add, that the attempts made by some persons who have borrowed my experience, and of which I have been witness, are far from being as clear as those which I show, and which have been obtained by taking all the precautions named above.

"Will a means be found of preserving these images when they remain

exposed to the rays of light? Will the arts be enriched by pictures painted by light? We cannot prove this. I simply make you a witness of my experience in all its details, to introduce to you a unique substance of its kind, which allows you to paint with light, and to render you able to reproduce easily the effects which I have obtained."

PHILIP E. B. JOURDAIN.

## FOREIGN NEWS AND NOTES.

**Combined Development and Fixation.**—In the *Photographische Mittheilungen* P. Hanneke gives an account of a process he has devised for this purpose. Starting with Punnett's idea, that hyposulphite of soda may be added to an ortol developer, which in his hands was successful for chloro-bromide transparencies, Hanneke has endeavoured to apply a similar method to bromide plates, for which purpose Punnett's process was unsuitable. After unsuccessful experiments with a large number of developers, pyrocatechin was tried and gave surprising results. For combined development and fixation, it is necessary that the developer shall act with rapidity and without producing fog, as it must take effect before the hyposulphite of soda attacks the image. The caustic alkalies favoured rapidity, but, in most developers, had to be used in such quantity that the film suffered if sufficient hypo to fix the plate were added. E. Vogel recently pointed out that, with a rapid pyrocatechin developer, an excess of caustic alkali is unnecessary. Hanneke has followed these lines, and recommends the following formula for preparation of a concentrated solution, to be afterwards diluted for use:—

Pyrocatechin .....	7 grammes.
Caustic potash (stick) .....	7 "
Hypsulphite of soda .....	30 "
Water .....	75 c. c.

According to Hanneke, the results are excellent, and he states that hyposulphite may be added *ad lib.* Modifications should be made in the proportions of the ingredients to suit the characteristics of different plates. For development of Sachs or Lumière plates he recommends:—

Stock solution, as above .....	8 c. c.
Twenty per cent. solution of hypo .....	15 "
Water .....	20 "

The developer may be used a second time without great loss of rapidity.

**Reduction with Ammonium Persulphate.**—The *Photographische Mittheilungen* draws attention to the fact that negatives thus reduced often exhibit red fog after exposure to light. This is due to the silver remaining in the film after reduction. The negatives, after reduction, should be rinsed, returned to the hypo bath for a few minutes, and then washed.

**Blue Tones upon Collodion Paper.**—H. Henrice writes in the *Photographische Chronik* that he has been experimenting for a long time in this direction. He declares it impossible to obtain blue tones with the combined bath. The results of some twenty or thirty modifications of the formula were always brown or violet, but never pure blue. He has obtained blue tones by separate baths, but has not been able to prepare a toning bath that will continue in the same condition long. It appears that the bath should be quite neutral, and that, as soon as half-alkaline or half-acid combinations of gold are formed, the tone changes to violet. Pure blue tones are best secured with the cyanide bath. The prints should be well washed before toning, and, with some papers, washing and slight fixing for three to five minutes is preferable. In the latter case the prints should be washed for a short time after fixing, but traces of hypo assist toning with certain brands of paper. The prints should not be too strong. They tone through stages of brown to blue, and in the case of landscapes some very effective combinations of brown foreground and blue distance can be obtained. The bath should contain little sulphocyanide and much gold. It should be prepared fresh each time, and used whilst still yellowish. Blue tones can only be obtained within ten minutes, or, in the case of very strong baths, within twenty to thirty minutes from the time of mixing. The solution afterwards becomes cloudy and yields only the usual violet

tones. Alkaline baths also yield a blue tone, but with less certainty and they are even less stable. If the prints are washed and fixed in a ten per cent. hypo bath for about three minutes, and then passed for ten minutes through three changes of water, they acquire very plucky, deep blue tones in the sulphocyanide bath, but the colour is less pure than after simple washing. Paper of the anchor brand should be toned with  $\frac{1}{2}$  gramme sulphocyanide, 100 parts water, and 2 c. c. of a one per cent. gold solution per 15 square centimetres of paper. To obtain the best results, the prints should be toned separately, each with fresh solution. It is useless to add more gold to an old bath, as the same results are not obtainable.

**The Keeping Qualities of Dry Plates.**—M. L. Hervé showed some lantern slides at a meeting of the Société Française which had been made with bromide plates fifteen years old. The fact acquires additional interest, inasmuch as M. Hervé had made the plates and had kept a record of the preparation of the emulsion. The formula was a modification of that published by M. Braun in March 1882, and may be described briefly as follows: Precipitation of silver bromide in presence of a very small quantity of gelatine, sufficient to form an emulsion; ripening the emulsion with ammonia; addition of water; decantation after standing a few days; final addition of pure gelatine. The process obviates wasting the emulsion. M. Hervé used less ammonia than specified by M. Braun, as he wished to make a slow emulsion, and had found the plates fog when prepared by the original formula. He also worked at a lower temperature. Some other slides were shown which were upon plates made in the same year, but without ammonia. The emulsion had been kept in very hot water for forty-five minutes, then boiled for fifteen to twenty minutes, and allowed to stand a week before decantation. These plates were still fairly good. The plates had been packed face to face, separated by sheets of tissue paper.

## SIMULTANEOUS DEVELOPMENT AND FIXATION.

DR. LUDWIG ELLON, of Charlottenburg, before describing his own process for this purpose, points out that the various attempts in this direction have in some special cases led to interesting results, but not as yet to a really generally applicable practical process.

Of recent labours in this direction he mentions those of Punnett, who, on p. 126 of THE BRITISH JOURNAL OF PHOTOGRAPHY for 1898, describes the obtaining of a fixed image with some kinds of diapositive or lantern plates (gelatine plates, containing chloride and bromide of silver) by the application of a strongly caustic alkaline ortol developer in the presence of a fixing salt.

But, with the best diapositive plates in the market, and strictly following Punnett's directions, he obtained an image of only very small intensity; and the bromide of silver-gelatine dry plates used for producing negatives, and therefore much more important, gave no image at all when used according to Punnett's process.

W. B. Bolton describes, on p. 804 of THE BRITISH JOURNAL OF PHOTOGRAPHY for 1898, and on pp. 20 and 52 of the same JOURNAL for 1899, a developing, strengthening, and fixing in one operation (not, however, for simplifying the process, but for obtaining perfect negatives), but he denies from his own experiments the possibility of applying successfully the process to bromide of silver dry plates.

It is also known that hyposulphite of soda easily dissolves bromide of silver exposed to light, and none of the heretofore-used developer solutions, including the so-called rapid developers, have been able to surpass in effect the said hyposulphite, or to yield a useful image by the presence of hyposulphite in excess. The pyrocatechin, in the form heretofore used, forms no exception in this application.

It is further known that slowly acting alkaline developers can be to some extent rendered into rapid developers by substituting caustic alkalies for the carbonates; but, while, for instance, with the isomeric hydroquinone three to four parts of hydrate of potash are required for one part of hydroquinone, in order to produce a rapid developer (which, owing to its strongly alkaline character, has only a limited application), pyrocatechin, on the other hand (and this is new), with the amount of alkali hydrate required for forming the di-alkali salt, or, with a still smaller amount of alkali hydrate, forms an extremely rapid developer. It is, in a concentrated form, composed as follows:—

I.	
Pyrocatechin .....	7 grammes.
Hydrate of potash .....	6 "
Crystallised sulphite of soda .....	30 "
Water .....	75 "

\* Photographische Correspondenz (1898), p. 561.

The application of the pyrocatechin alkali developer, also in combination with fixing salt (hyposulphite), gave at once a splendid result. For a dry plate 18 by 18 m. m. is used:

## II.

Concentrated developer I .....	10 c. c.
Soda fixing solution 1 to 5 .....	20 "
Water.....	20 "

Without prolonging the time of exposure beyond the usual, one obtains, by instantaneous or by time exposure in the course of three to five minutes (all according to the kind of plate used), a perfect, well-graduated, nicely covered, and perfectly fixed negative.

An unexpected advantage of the process shows itself here at once, in that the whole process is completed in a fraction of the time heretofore considered necessary for a successful process.

The used developer may be used for a second and third plate.

The fixing developer equalises various degrees of exposure, so that even a much over-exposed plate, when treated with a freshly formed developer, yields a negative that can be copied. Like the ordinary developer, it may easily adapt itself to various cases by dilution, by applying used developer, or by suitable additions, such, for instance, as bromide of potash and the like. The fixing developer may thus also be successfully used for films, bromide of silver paper, or lantern plates. Very remarkable results are obtained with the latter while using a developer composed, for instance, as follows:—

## III.

Concentrated developer I .....	5 c. c.
Soda-fixing solution 1 to 5 .....	40 "
Water.....	10 "

A perfectly clear and good image is thus obtained in the shortest possible time.

Instead of the hydrate of potash, I may, with quite similar success, employ hydrate of soda, or of lithium, or a mixture of two or three of these bases, and I may also let other subsulphurous alkali salts partly or wholly take the place of the subsulphurous soda (hyposulphite).

The aforesaid relative amount of alkali in the developer is only chosen as an example; it may be varied, within rather wide limits, without rendering the success of the process quite doubtful.

The technical value of the described new process would thus not only depend upon that it at once solves the old problem by the developing to obtain enduring photographic images in a surprisingly simple and yet complete manner, thus effecting a material saving to the amateur and the professional photographer in time, labour, and tools, but also on the circumstance that it gives results so distinctly good as not to be attained so easily and certainly by the heretofore usual process.

## A NEW PHOTOGRAPHIC PRINTING PROCESS IN A NEW PERMANENT COLOUR.

[Communication to the Edinburgh Photographic Society.]

THE new printing process which Mr. Hargreaves brought before the Society was one by means of which he was enabled to produce prints of a deep purple, and a light red colour on a cotton or linen fabric. After explaining that he appeared as a chemist only, and after discussing the dyes used by the ancients, referring specially to the Phœnician or Tyrian purple, Mr. Hargreaves continued as follows, viz.:—

"In fixing colours upon any desired surface, such, for instance, as paper or cotton cloth, there are two distinct methods, which, in order to thoroughly understand, especially in the case of the cotton cloth, it is necessary to inquire into the physical characteristics of the cotton filaments which go to make up what is popularly known as a cotton thread. These extremely fine filaments are really tubular, but they have the peculiar characteristic of being flattened or collapsed. It was by this peculiar property that it has been definitely proved that the cloth which surrounds the ancient Egyptian mummies was linen and not cotton. These wrappings, it may be observed, are the only specimens we have of the productions of the looms amongst the nations of antiquity, and, although it was doubted for a long time as to the actual fibre, the microscope has definitely shown that they are not cotton but linen, and this has been effected by the flattened condition which cotton filaments always possess. The walls of these fibres, which are really tubes, are exceedingly fine, porous, and more or less netted and transparent.

"Now, colouring matters are of two kinds, the soluble and the insoluble. The former are those which are in a perfect state of fluidity, or in solution; the latter are lakes or pigments. When a fluid colouring matter is applied to a cellulose fibre, it is very easy to understand that it passes easily through the netted or porous walls of the cellulose tube; but, of course, it passes outwards with the same facility, and such colours are generally not fast, that is, they easily wash out.

"On the other hand, a pigment or lake, owing to its particles not being sufficiently fine, cannot penetrate within the tube, and so are merely plastered on the outside, and will not remain unless some adhesive matter is also applied, and, even in this case, cannot be regarded as being any better than a paint.

"The truly beautiful and permanent effect of the colouration of textile fabrics can only be produced by so arranging the colour that, say, one of its constituents dissolved in some volatile solvent is applied to the fibre, and, on drying, the chemical becomes insoluble, and is practically locked within the tube, in which condition it is usually spoken of as a mordant. The cloth is then immersed in a solution containing the other constituent. The latter enters within the tube, combines with the other constituent already present, and forms a coloured lake or pigment, which is imprisoned within the tube. This is the true principle of dyeing. The effects produced are always superior in depth and beauty of tone to mere plaster, and this brings me to the specimens which I have the honour to bring before your notice.

"Being engaged recently in some investigations relating to the flashes of various explosives (a few specimens of which I have here to-night, taken by Mr. M'Kean), I turned my attention to the printing of negatives, and, having some acquaintance with the dyeing and printing of textile fabrics, I endeavoured to see whether it were possible to obtain a photographic print on bleached cotton cloth, a condition being that the colouring matter should enter the cotton filament and thus secure absolute fixity. This, I venture to think, I have done. The colour which I have succeeded in fixing in this way is a beautiful purple. It cannot be washed out of the cloth by any ordinary method of, say, a boiling soap solution, and, what you will probably regard as more important, it is, in my opinion, quite permanent so far as the action of light is concerned. It is, in the daytime, a very beautiful colour, and the effects on the cloth are exceedingly soft and easy for the eye to rest upon; and, lastly, the process is one of extreme simplicity and cheapness. Practically any number of prints can be developed together, tumbled about in any fashion without any care being exercised, and, when the patent specification is published, as it will be in a few months, I venture to think that you will appreciate its extreme simplicity."

Mr. Hargreaves then showed a number of specimens, and tested the fastness of one successfully by boiling it in a soap solution.

ANDREW F. HARGREAVES, F.C.S.

## PRACTICAL NOTES ON SOME IRON PRINTING PROCESSES.

### PART II.—FERRO-PRUSSATE, &c. (continued).

*Printing.*—A fairly strong plucky negative gives the brightest results. Printing should be in a strong light and may be in direct sunshine. If the paper is old, something akin to reversal shows in printing. Printing goes on until we have greenish high lights on a pale lilac ground.

*A drawing, diagram, &c.,* consisting of black lines on white paper, may be used in place of a negative. The resulting print shows, of course, as white lines on blue ground. Where reversal of the picture (right to left) is of no consequence the sharpest results are obtained by putting the face of the engraving in contact with the sensitised surface and printing through the back of the engraving in direct sunlight.

Name of diagram, &c., may be written in red if ordinary red ink is acidulated with oxalic acid. The acid removes the blue colour, and the red ink remains. One part of acid in twenty of ink will be found generally satisfactory.

*Development* essentially consists in washing (dissolving) the unaltered parts of the sensitising mixture. The washing water should be as free from lime or chalk as possible. If lime is present to any great extent, carbonate of iron may be formed and the lights stained.

Prolonged washing in running water, or in frequent changes, helps to clear the whites.

*To brighten the colour of the prints, a trace of acid, e.g., citric, hydrochloric, &c.,* may be added to the washing water.

*Over-exposure* can be partly counteracted by bathing the print in a very dilute solution of ammonia, e.g., begin with ten drops of strong ammonia in a pint of water, and add a few drops at a time until the print is lightened sufficiently.

Again, a dilute solution of oxalic acid (say, five per cent.) has a similar action.

*Under-exposure* may, to some extent, be compensated for by developing the prints in a dilute solution of iron perchloride. The proportions of perchloride recommended vary from 1 in 300 to 1 in 120 of water; but 1 part iron to 200 parts water will be found a generally useful strength. Iron protosulphate or iron nitrate may be used in place of the perchloride, with similar results, but the last-named seems the favourite.

*Reduction of an Over-printed Proof.*—Immerse the print in a five per cent. solution of caustic potash until the image turns pale yellow. Wash well, and transfer to water containing a little hydrochloric acid (ten drops per ounce). The print again becomes blue, but is reduced in strength generally.

*Intensification.*—This may be done by immersing the print in a five per cent. solution of potassium sulphocyanide.

*Toning Blue Prints.*—Many experiments have been made with a view to altering the colour of a blue print. In certain directions considerable success has resulted.

*Brown-black.*—The print, having been previously well washed and dried, is immersed in dilute ammonia (5 in 100), until the image is

W. B. BOLTON.

DIED MAY 12, 1899, AGED 51.

almost invisible. Again washed and transferred to a bath of tannic acid (5 in 100), washed and dried.

*Another Method.*—Immerse the print first in dilute caustic potash (8 in 100), rinse, and transfer to tannic acid bath (5 in 100), or, in place of caustic potash, we may use potassium carbonate solution (5 in 100).

*Another Method.*—Make a saturated solution of soda carbonate; dilute this with its own bulk of water; to this add as much tannic acid as the solution will dissolve. Into this mixture plunge the prints until they attain the desired darkness; wash and dry.

*Brown-black Tones: Another Method.*—Bleach the blue print in a cold saturated solution of borax; wash well, and transfer to a saturated solution of tannic or gallic acid; wash again, and give a final bath of acetic acid (3 in 100).

*Another Method.*—Make a ten per cent. solution of potassium sulphocyanide; to this add a small quantity of lead acetate. The prints are immersed in this, dried without washing, and exposed to daylight. This ought to yield a fine black.

*Another.*—Immerse the prints in a five per cent. solution of potassium carbonate. Wash, and transfer to bath composed of 1 part acid pyrogallie, 12 parts gallic acid, water 1500 parts. If the pyrogallie acid is omitted, the colour tends to violet rather than black.

*Brown-black.*—First bath the print in dilute nitric acid (1 in 80). Transfer to bath of dilute ammonia (1 in 25), until the print becomes faint and reddish-yellow; then transfer to a 1 in 20 bath of tannin, or extract of catechu.

Float the print on a bath of nitrate of silver (1 in 60). When the image becomes almost invisible, remove and wash well. The print may now be developed with the ordinary ferrous-oxalate mixture. Transfer to dilute hydrochloric acid (1 in 200), wash and dry. This process will yield black prints.

For red-black tones reverse the alkali-tannic procedure thus: Soak the print for five to ten minutes in a bath of tannin (1 in 25); then transfer to a bath of soda carbonate of similar strength (1 in 25).

*Brown-black Tones.*—Immerse the print in a 1 in 25 solution of caustic potash until orange grey; wash and transfer to 1 in 20 gallic acid, and rinse in dilute hydrochloric acid, 1 in 50. Now float on a 1 in 50 bath of nitrate of silver; wash well, and transfer to old (used) hydroquinone developer. If, after the nitrate of silver bath and subsequent washing, the prints are exposed for a short time to strong daylight, the results are better still.

*Blue-black.*—Print strongly till shadows bronzed; dip in water, then in three per cent. solution of ammonia until pale violet; then immerse in a six or eight per cent. solution iron proto-sulphate.

*Deep Blue Tones.*—Of saturated solution of ferrous sulphate take 8 parts, add 8 parts water, and then 1 part sulphuric acid.

*Sepia Tones.*—Bath the print in caustic potash, 1 in 20, until the image is of an orange tinge; then transfer to tannin bath (say 5 grains per ounce of water); then another dip in the caustic potash; then wash and dry.

*Lilac Tones* may be obtained by immersing the prints in a hot solution of lead acetate. Lilac tones also are obtainable by very dilute solutions of borax or potassium oxalate. If these lilac prints are dipped in dilute potassium sulphocyanide and exposed to light (without washing), they assume a slight pinkish tinge.

*Green Tones.*—To 100 parts water add 5 parts sulphuric acid; immerse the prints until the desired tint is obtained; wash slightly, and dry. Again: Prepare a thirty or thirty-five per cent. solution of potassium sulphocyanide. This bath gives tones ranging from moss-green to brown-black.

*Varnishing.*—Blue prints may be varnished by applying with a brush a solution of Canada balsam in turpentine, and drying in a strong draught. Dammar varnish may also be used.

*Corrections* may be made, i.e., portions of the blue part removed, by applying, with a quill pen or small brush, a strong solution of oxalic acid; or a strong solution of washing soda may be used. Care must be taken to see that the action does not spread.

*Contraction of the Print.*—Where this process is used for reproducing plans, &c., it is important to notice that, with certain papers, there is a general shrinkage or contraction in the paper. Therefore the scale should always be included in the print, if measurements are to be made from the reproduction. The contraction may be as much as one per cent. of the linear dimensions.

*To Convert a Blue Print into a Line Drawing.*—Having previously well washed and dried the print, trace the outline, &c., with good Indian ink, rather thick, and let it dry thoroughly. Then dip the print for a few moments in a five per cent. solution of oxalic acid, or potassium oxalate, or ten per cent. washing soda, until the blue colour is removed, leaving only the black lines. In place of Indian ink, waterproof ink may be employed.

*Retouching Blue Prints.*—Make a saturated solution of iron proto-sulphate, and add to it a ten per cent. solution of potassium ferricyanide; collect and wash the precipitate. Mix with a little gum water and apply with small brush.

*Sundry Notes.*—(a) Ammonia citrate of iron is also known as ammonio-ferric citrate, and as citrate of iron and ammonia.

(b.) Potassium ferricyanide is sometimes spelled ferridcyanide; also known as red prussiate of potash.

(c.) If blue fog occurs when using the green form of ammonio-citrate of iron, it is an indication that the sensitising mixture contains too much potassium ferricyanide.

(d.) If the light is not sufficiently strong to admit of the print being fully printed in the time available, it may be developed (when only partially printed) by immersing in the following. In two gallons (sixteen pints) of water dissolve one ounce of chloride of iron and a like quantity of nitrate of iron.

(e.) Several authorities advise a strongly sized paper and recommend—

Arrowroot .....	4 parts.
Glucose .....	1 part.
Water .....	200 parts.

Dissolve by heat. Skim and strain through muslin and apply hot with a soft clean sponge.

REV. F. C. LAMBERT.

## FLASH POWDERS.

[American Journal of Photography.]

THE sun is not the only source of radiation which produces chemical effect. Any substance which, when heated intensely, resists all tendency to conversion into vapour or gas—that is, remaining still in a solid condition—will give a continuous spectrum, analogous to that of the sun. It will emit the so-called actinic rays.

There are several bodies which resist the vapourising power of the intensest heat we are able to produce on earth, though they do yield to the solar heat. Such bodies give a continuous spectrum from the red to the violet. The carbon points of the electric light arc yield a pure white light with the uninterrupted spectrum, and such as is capable of producing chemical action and may be employed in photography. Incandescent lime, magnesia, zirconia, and other substances likewise give forth the chemical light. It is for this reason that the Welsbach light may also be employed photographically, the mantle being composed of these incandescent earths. Magnesium metal is especially rich in the blue rays of the spectrum, and, though the light it produces when ignited is not so intense as the electric light, it is still capable of producing in an equal degree photographic action.

There is chemical action in all the rays of the spectrum, but the blue have the preponderance.

The light from magnesium is a beautiful soft light and would form the ideal light for illuminating purposes, but the rapidity of combustion precludes its use, even if it could be made cheap. But for photography nothing is equal to it except, perhaps, aluminium. Magnesium, when supplied with oxygen, is converted into magnesium oxide—or magnesia, as it is generally called. The burning in air or in oxygen gas is attended with intense heat, which causes the particles of solid magnesia to grow incandescent. Bunsen estimated the light of incandescent magnesia to be in intensity only  $\frac{1}{100}$  of that of the light of the sun, while its actinic or chemical energy is  $\frac{1}{10}$  of the sun's—that is, the sun's light is 500 times stronger than burning magnesium, but only 86 times stronger in actinism. To get the whole benefit from the burning metallic magnesium, it will be seen that anything which increases the intensity of the heat will increase the actinic light. The ribbon or wire burns comparatively slow when ignited in the ordinary air, because the supply of oxygen is diluted, but how it glows when burned in a jar of pure oxygen! Hence bodies which quickly and readily supply it with oxygen during its combustion increase its energy. When the mechanical means were improved for converting the metallic magnesium into a fine powder, it occurred to many to mix it with some oxygen-yielding chemical and so increase its power. Pure magnesium, without any substance mixed with it, will give photographic effect, but a great deal of its usefulness is lost thereby, though in many cases its power is sufficient, especially when instantaneousness is not desired.

The danger attending the compounding of other chemicals with magnesium has led many to employ it alone, and lamps are in the market for giving a continuous flow of powder to the flame. But there is a risk of recording movements in the photograph—and to get snapshots by its use alone is out of the question.

Messrs. Gædicke and Miethe, of Germany, some years ago patented the use of magnesium compounds for photography, but no one seems to have introduced their powder to the market, neither in England nor America, or, as far as I can discover, even in their own country. Their claims, however, were published in both the English and German photographic journals, and it is surprising to me that no one ever recommended the mixture for efficacy. The peculiar feature which made their powder different from others was the introduction of amorphous phosphorus in connexion with powdered magnesium. Amongst the many formulae published, I have not been able to find any mention of the use of this chemical other than in the brief specification published with their patent. They mention, it is true, amorphous phosphorus combined with magnesium and chlorate of potassa, but I am sure they were well aware of the danger of employing such a violent explosive, which mere friction of stirring with a feather will cause detonation.

Although chlorate of potassa cannot be used, the nitrates of some of the earths, such as baryta or strontia, may be safely employed in com-

bination with magnesium and amorphous phosphorus. The barium and strontium nitrates are preferable to the alkaline nitrates, as they are less liable to absorb moisture from the air; but even they should be thoroughly dried before mixture, and so should the amorphous phosphorus.

Take 4 ounces of nitrate strontium (dried) and mix it thoroughly with 1 ounce of metallic magnesium in fine powder; this may be done by sieving through a rather fine sieve, which will serve the further purpose of separating any large grains of magnesium, which cause a miniature sky rocket if left in the powder and make a streak across the plate. Instead of using all strontium, one-third barium oxide may be substituted.

To the mixture of baryta, strontia, and magnesium, add from 50 to 100 grains of amorphous phosphorus. Increase of amount of phosphorus will increase rapidly of the powder, so that, if a very rapid powder is desired, 120 grains may be used.

The amorphous phosphorus should be added last by way of caution, but I think there is little danger to be feared in the mixing. The powder formed will stand considerable friction, and probably is no more liable to explode spontaneously than gunpowder, but even with gunpowder it is well to take care and not presume.

However, let me say here *no compound flash powder should ever be compressed and ignited in a lamp intended to burn only pure magnesium.* Though comparatively safe when ignited unconfined, it becomes a blasting powder, like gunpowder, when rammed or compressed.

Amorphous phosphorus is sometimes called red phosphorus. It is a modified form of common phosphorus, but entirely unlike it in many respects. It is not poisonous, does not ignite until heated to over 500° F., and is not luminous in the dark. The drying of the amorphous phosphorus should not be done over a naked flame, and care should be taken to sieve it first through a fine sieve before mixing with the other ingredients.

It will be seen that the use of flash powder is much more economical than the use of pure metallic magnesium, inasmuch as one has five times as much powder for a little extra expense, and then the same quantity of flash powder as magnesium will do more than threefold the work of magnesium.

A slower form of flash powder may be made by omitting the amorphous phosphorus and mixing 5 parts of peroxide barium (dried) with 1 part of magnesium. Portraits may be made with such a mixture, and I would estimate its rapidity at about one second, while that of the amorphous mixture is probably less than one-tenth of a second. This compound may be made as rapid as the above mixtures of baryta and strontium by adding the amorphous phosphorus. It has the advantage of producing less smoke, and is entirely free of the unpleasant odour which attends the above mixtures.

Recently I read of a compound which is said to give good light with very little smoke—an objection to most powders. It may be prepared, according to Prof. Alex. Lainer (*Phot. Correspondenz*), by mixing equal parts of magnesium powder and of ammonium nitrate. The ammonium nitrate being somewhat hygroscopic, it is necessary to fuse the salt before its use, and to keep it pulverised in a well-stoppered bottle. The powders should be perfectly dry and finely powdered, and then mixed with a feather on a sheet of paper. As to the quantity of the required flashlight powder, the author states that he has obtained perfect negatives, with plenty of detail in the shadows, by using a mixture consisting of 0.3 gramme (about 5 grains) of magnesium powder and 0.3 gramme of ammonium nitrate, the lens being stopped down to f-7, and the distance of subject from the lens amounting to about 6 feet. The volume of smoke given off was so small that five subsequent exposures could be made in the room without the least disturbance to the occupants. In taking a photograph of a room of 15 by 15 feet, the author obtained a sufficiently detailed negative by using a mixture of 1 gramme of magnesium powder with 0.8 gramme of ammonium nitrate. The rate of combustion with this new flashlight mixture is, perhaps, not quite as rapid as with the above mixtures, but, nevertheless, it is sufficiently quick to enable the operator to photograph by means of it portraits and groups, provided that the constituents of the mixture are perfectly dry and finely powdered, and that the mixture is spread over a thin film of gun-cotton, which may be ignited by means of a taper fastened on a long rod.

I have not tried this smokeless powder, but would here caution any one not to try to increase its rapidity by addition of amorphous phosphorus unless they make the experiment at first with very minute quantities. I am inclined to think that even the mixture of ammonium nitrate and magnesium should be made with care.

A word about the use of aluminium in flash powders. It might seem astonishing that so slightly oxidisable a metal as aluminium should be made to burn with a very brilliant light. True, in the shape of wire or ribbon it will not burn when placed in the flame of a gas jet, but when the heat is intense it burns with a beautiful light and affords an energy equal to magnesium. It has one advantage over magnesium. Very finely powdered magnesium soon tarnishes and becomes almost useless, so that, when the other ingredients of the flash powder are such as attract moisture, it is necessary to keep the powder closely protected from damp atmosphere. Fine aluminium powder will keep for years at ordinary temperature without oxidising, but aluminium powder must be exceedingly finely ground to be of any use photographically. Coarse-

ground magnesium will ignite without difficulty, but aluminium must be in the form of what is called silver bronze before it will burn with the flame of alcohol or gas.

I have found that about twenty-five per cent.—that is, one-fourth—aluminium with magnesium, the other components remaining the same, will give an excellent flash powder.

GEORGE RAU.

## SOME ADVANTAGES IN THE USE OF FILMS.

[Communication to the Edinburgh Photographic Society.]

DOUBTLESS the bulk, if not all, of the members present are more in favour of plates than of films. Anticipating this, I have thought, as a counter-blast, to indicate a few of the good points of films, and, if possible, to modify the adverse views regarding them.

Films are much more portable than plates. Space for space, you can get five packets of films in the space of one packet of plates, while one packet of films weighs one-sixth part of a packet of plates. I use the word packet, because these data are taken by comparing packets. If the bare plates and films were taken, the comparison would be still more in favour of the films.

I need not enlarge to any extent on this advantage. The tourist or traveller, be he a hill-climber, cyclist, or pedestrian, asks for something light and portable. He gets it in films as against plates.

Films are non-breakable. We all know what it is to have a pet glass negative broken. How many questions arise regarding how to print a broken negative, how to float a film from a cracked plate, and so on. The photographic question-box would be void of such queries, and the time of societies thus saved, if films were used instead of plates.

Risk of transmission by post or rail would not concern the photographer if he used films. It is not the first time that it has been the duty of the law courts to decide as to the liability attendant on the breaking of a glass negative. Tourist friends abroad can, with every safety, and with minimum cost, transmit exposed films to their folks at home for development; whilst, if the exposures had been made on plates, there would be great risk and expense in transmitting them.

With the ever-increasing number of amateur photographers, the foregoing claims of films have, doubtless, induced many of them to join the ranks.

Now as regards the efficiency of films. There have been, and still are, defects to contend with. These defects, I venture to say, are mechanical, and in a very short time will be quite overcome. The quality of the emulsion is equal to the best; the defect all lies in the support. Strange and apparently unaccountable markings on film negatives have been carefully looked into by the makers, and I am convinced they will soon be blemishes of the past.

Consider the storing of film negatives as against plates, and the small space occupied by a book containing a hundred films as compared with two bulky boxes to hold a hundred plates. Film negatives are also practically, if not entirely, free from halation, and cloud effects are easily obtained on the same film as the subject proper. Plate negatives, even when backed—and backing plates is a troublesome operation—are not void of this evil.

Carbon workers need not make reversed negatives; all that they require to do is to photograph on thin film, when prints may be taken from either side.

As a further argument, a prize picture in our own Exhibition of a year ago was taken on a roll film.

Roll-film photography is a distinct advance in the art. I cite the cinematograph and its results as my reason for this statement. Where would the cinematograph have been without the roll film? We would still be climbing up the hill "Difficulty" with a burden of plates on our back.

Mr. Chairman, we are told "the proof of the pudding is the tasting of it;" the proof that film photography is holding its own and making rapid strides to the front is shown by the following specimens.

Mr. Baird then exhibited a number of quarter-plate, 5 × 4, and 7 × 5 film negatives, and showed several enlargements from these.

A. H. BAIRD, F.R.P.S.

## FLASHLIGHT PHOTOGRAPHY.

At the Photographic Club Mr. Reinhold Thiele attended as promised to take a group of the members with the Weiss flashlight apparatus described last week. On this occasion he had with him a specially designed automatic smoke trap wherewith to prevent the smoke arising from the combustion of the flash powder from pervading the premises. The flashlight apparatus was supported upon a brass standard and was adjustable to various heights by a telescopic movement and damping screws. The actual smoke trap partook somewhat of the form of a balloon, and was made of some fireproof material. It was suspended by an arm over the lamp, and when ready for action its sides are gathered up together with a weighted hoop attached to the lower end, and hitched over two levers. These levers in turn are connected by a cord to a silk thread, which passes across the path of the igniting match which fires the

powder, the object being, when the flash has been made, for the silk to be burnt, so releasing the levers which, dropping, allow the weighted skirts of the bag or balloon to drop and enclose the smoke. The lower end of the bag is closed by drawing a string, the bag lifted off the standard by means of a bayonet joint, taken to a window and the smoke discharged. Mr. Thiele made an exposure, promising to send the result on another occasion.

Mr. Luboschcz showed some photographs resulting from his experiments in flashlight photography, the exposures being practically instantaneous. The absolute sharpness of every detail was in his opinion almost unpleasant, and he thought that if the exposure had been slightly prolonged, giving the effect of a time exposure, the results would have shown a more pleasing diffusion. His examples included some work by flashlight done in the United States of America upon the stage, and others showed the effect of lighting the sitter from several different points. Several of the pictures measured  $22 \times 18$ , and were taken direct. Mr. Luboschcz believed Mr. Falk had done a little in the direction of stage photography by the usual stage lights, but generally supplemented with arc lamps. Referring to some remarks about diffusion of focus, he said that he had seen this effected by holding the flame of a spirit lamp in the path of the rays immediately in front of the lens. Mr. Luboschcz afterwards gave his views upon the subject of development, advocating the use of diluted solutions until by the appearance of the image one could be guided as to what was really the condition of the exposed plate. For the avoidance of halation in a plate which would otherwise show it, nothing was better, he held, than development with plenty of water.

The Chairman dealt in a few sentences with the merits of rodonal for under-exposed plates. One or two minims of rodonal to the ounce made a developer in which the plate could be left for some hours unattended until every detail possible was brought out. A strong solution used for a quarter of an hour then sufficed to yield the best result that could be got from an under-exposed plate.

#### VIEWING LARGE STEREOSCOPIC PHOTOGRAPHS.

[Photographic Times.]

RECENTLY, in making some experiments in optics, it was found desirable to view very large pictures stereoscopically, even stereopticon slides projected, and the writer set about its accomplishment. Apparently there are but two simple conditions involved, i.e., (1) that two pictures (the size is of no moment) shall be made from different positions, say, three inches apart, and (2) that this stereoscopic pair shall be so viewed that the right eye shall see only the right picture and the left eye only the left picture.

Working upon this simple hypothesis, two  $22 \times 24$  negatives were made and prints made and mounted in the usual manner. To make them appear in stereoscopic relief, they were viewed through a binocular eyepiece containing four total reflecting prisms so located that the right

picture was seen by the right eye through the two prisms in front of the right eye, and the left picture by the left eye through the two prisms in front of the left eye. An adjusting screw was provided, which permitted the exact superposition, at varying distances, of the mental impressions of the retinal images of the two pictures. In the construction of other eyepieces magnifying lenses were added, giving a stereoscopic picture of great size, beauty, and atmospheric effect.

Pieces of mirror may be substituted for the more expensive prisms, and even two pieces may be used, each set at  $45^\circ$  to the line of vision, if the pictures are placed some distance apart, with their surfaces parallel, and viewed from a middle point.

The eyes are much more independent of each other in action than is

generally supposed. To demonstrate: If one looks at a single object through this instrument, properly adjusted, the object appears natural. Now, by turning the adjusting screw slightly, two images appear, only for a moment, however, for the eyes actually change the angle of vision without changing focus. By turning the screw farther, the angle can be still further changed, the eyes again assuming the new position. This can be continued in easy steps until the muscles fatigue, and, relaxing, resume their customary angle for that focus. It will then be noticed that there are two images. (Incidentally, engineers, microscopists, &c., who are accustomed to use the eyes more or less independently, are able to decrease the angle of vision much farther than others.) This leads me to believe that, by the use of this instrument, the eyes of "cross-eyed" children may readily be corrected by the purely gymnastic exercise suggested above, and the few experiments made bear out this belief.

In this connexion it may not be amiss to mention an interesting observation in this line. To measure, unaided, the distance from centre to centre of one's own eyes, all that is necessary is to hold the first and second fingers, about three inches apart, before the eyes, meantime looking past them, focussing the eyes infinitely far in the sky. There will appear, indistinctly, four fingers. Gradually close the fingers until but three are seen. They are now exactly the width apart of the pupils, and represent the distances two stereoscopic pictures should be placed from centre to centre to be easiest viewed stereoscopically by the unaided, trained eyes. A pair of dividers may be used for more accurate measurements.

C. FRANCIS JENKINS.

#### HYDRAMINE: A NEW DEVELOPER.

[Revue Suisse.]

AMONG the numerous substances which we have obtained in our experiments on introducing developing groups into amines and phenols, we may draw attention to one of which we have made a special study, which, when used as we describe below, forms an excellent developer. It is a definite combination of hydroquinone and paraphenylene-diamine, obtained by the direct interaction of these two substances, and is, according to our analysis, a molecular compound of these two bodies without the elimination of any elements. It is possible that the two hydroxyl groups of the hydroquinone are saturated by the two amidogen groups of the paraphenylene-diamine, the groups which give rise to the developing properties of the two substances being left intact, as the formulæ represent:—

To avoid the difficulty of naming this compound in accordance with its chemical constitution, we propose giving it the purely conventional name of "hydramine."

Hydramine occurs in beautiful white scales, melting about  $194\text{--}195^\circ\text{C}$ . to a brownish red liquid. It is sparingly soluble in water (1 part in 500 parts of cold water), more soluble in hot water (five per cent. at  $100^\circ\text{C}$ .), sparingly soluble in cold alcohol, soluble in acetone, and dissolves easily in acids and alkalis. The alkaline solution becomes gradually brown in the air, but the change is retarded by the presence of soda sulphite. At a boiling heat acids and alkalis decompose it into its two components. Ferric chloride gives, in aqueous solutions, a dark blue colour, changing rapidly to dark red. Excess of ferric chloride converts the compound into quinone.

A plain solution of hydramine in water is a developer of the latent image, but its action is so slow, and the resulting image so feeble, that, from a practical point of view, the developer in this form need not be considered.

Sulphite of soda, added to this aqueous solution, does not increase the developing power, a difference which marks off hydramine from compounds which contain two developing radicles in the same aromatic nucleus. Even if alkaline carbonates be added to the solution, which already contains sulphite, it is not possible, however the proportions of sulphite and carbonate be varied, to develop a vigorous image; the plate develops slowly, and the negative is flat.

If tribasic phosphate of soda is used in place of the carbonate, the development is quicker, and yields a more vigorous, though still flat, image, and this happens whatever proportions of reagents are employed. Acetone and sulphite of soda, in conjunction with hydramine, give an energetic developer, which gives stronger images than does carbonate or tribasic phosphate, but still very inferior to those resulting from the use of a small dose of caustic lithia in the developer. But we will not further dwell on the various ways in which the developer can be "alkalinated," except to speak of what we consider the best, viz., with caustic lithia.

Very small quantities of lithia, added to the soda sulphite solution of hydramine, greatly augment its developing power. The image appears quickly, and the half-tones show a normal gradation. With a view to determine the best formula, we tried various proportions of sulphite and of lithia. We found the best proportion of sulphite to be 15–16 grammes of anhydrous salt per litre (=13–14 grains of crystallised sulphite per ounce). More causes loss of vigour; with less the solution deteriorates quickly. If the lithia is kept below 2 grammes per litre

( $\frac{1}{15}$  grain per ounce), the image is feeble; 3 grammes per litre ( $\frac{1}{15}$  grains per ounce) is the best strength. The addition of any more will not increase the energy of the developer.

We may put the normal developer as follows:—

Hydramine .....	5 grammes	2½ grains.
Sulphite of soda (anhydrous)...	16 "	7 "
" " (crystallised)...	"	14 "
Caustic lithia .....	3 "	1½ "
Water .....	1000 c.c.	1 ounce.

This solution gives good gradation in the half-tones; the image comes up quickly, gains strength gradually, and can be brought to an intensity equal to that given by the most energetic of developers. Owing to the low proportion of alkali, there is no softening action on the gelatine. The solution, prepared as above, is colourless, and will keep practically unchanged in a corked bottle. It does not stain the skin to any extent worth speaking of.

One point which must be mentioned is its great sensitiveness to the action of potassium bromide. One c.c. of a ten per cent. solution has a very marked action on 100 c.c. of developer (this is at the rate of  $\frac{1}{4}$  grain per ounce of developer). With 10 c.c. of potassium bromide solution development is quite arrested, so that it will be seen that the developer lends itself freely to the correction of over-exposure.

In conclusion, it is curious to note that the direct combination (without elimination of water) of two bodies possessing developing properties—of which one, hydroquinone, is acid, and the other, paraphenylene-diamine, is basic in character—should give rise to a compound possessed of such striking developing properties as to act properly in conjunction with a small quantity of caustic alkali. That hydramine does act thus must probably be attributed to the fact that the groups of the two components saturate each other.

It is equally interesting to note how different is the action of alkaline carbonates, acetone, sulphite, and tribasic phosphate of soda upon hydramine from what obtains with many developers, with which these alkalies or their substitutes react like caustic alkalies.

Lastly, the retarding action of small quantities of bromide is equally noteworthy, for it is well-known that this is exhibited in connexion with only a few organic developers.

LUMIÈRE BROTHERS AND SEYEWETZ.

### THE LADY IN THE RECEPTION ROOM.

For a lady to be a success in the reception room she must be well supplied with tact, highly intuitive, a quick thinker (says Miss Ida M. Smith in *Wilson's Photographic Magazine*), slow to anger, and pleasant and courteous in manner, straightforward, energetic, and business-like in conversation, careful and artistic in dress, but not over-dressed. Add to this a knowledge of people and business, and she will win the confidence of all classes. She should have a feeling of joy and pride in her work, and be allowed freedom in method. A look into other studios and a chat with other work people will aid in the matter of enthusiasm, stimulate self-improvement, and preserve a cheerful disposition. Courage is half the battle in dealing with people. As a person enters the room I "size them up," and am ready for them by the time it is necessary to discuss styles and prices. The successful clerk at the dress-goods counter will bear more imitating in many ways, but I must do more than he. Whether I get the order or not, I must make friends, and, if they are not ready for a sitting, I must make them feel that we can do the work satisfactorily. I assure them that it is a pleasure to show samples, and, should they call again, will be glad to make it a special point to please, and hand them a card, so that they will not forget the place. I must know how to make suggestions as to dress and arrangement of hair, or in many cases I will fail. To admire a dress a lady is wearing will sometimes catch an order. If a child is brought in, I must admire it, whether it be a prospective subject or not. The mother knows the child is pretty, and I ought to. As far as possible I try to make a person feel that I am studying to give them just what they will feel best satisfied with when the work is finished. I believe truthfulness will work best in the end, but I need not utter painful truths. Policy and tact will keep the path smooth. Stating prices should be done incidentally; I often show the \$8.00 work when I know the \$5.00 work is wanted; \$5.00 will sometimes frighten, when it will not sound so bad after hearing the higher price, while others would rather pay \$7.00 for the \$5.00 work. While one customer must wait for another, I try to entertain the one who waits.

I make it a point to examine all negatives before proofs are made, and retouch where improvements can be made. Having secured my proofs, I study them, to know them and be ready to meet criticism or make suggestions should a resitting be desired. I think it poor policy to persist in urging a person to accept a proof they do not like, unless they be of the number who are never pleased or desire unreasonable things. No matter how good a negative may be as to lighting, exposure, and development, if the expression is blank or troubled, or the posing stiff, it should never be urged unless it be the best that can be done with that particular patron.

While I am showing a proof, my time is fully occupied; it is no time to talk prices to another. The average person imagines it a mark of

modesty to frown at a proof, and, after a little fussing, will grant that it is a good picture. If I am sure the proof will call out favourable comment, it will aid me greatly to show the proofs while another is looking around. The same rule holds good in delivering work.

Having once secured a name, I must remember it if possible, but, if not, must remember the face, and, by a little tact, can get the name without saying that I do not know them. Sometimes I can recall circumstances and find the name by referring to the book. A little real study and method will make this comparatively easy, and is well worth the effort. Where I feel sure of pleasing without harming myself, I make it a point to recognise customers on the street or at public gatherings.

If it is made an object to a lady, she can cultivate a wide acquaintance and draw trade; but it is expensive to be much in society, and she cannot do it unless there is some recompense.

To do my best, I must not be crowded every moment and required to put in my time just to make sure I earn my wages. I must do some thinking, and it must come in during working hours. If I work faithfully the year round, unless my wages are especially good, I think I have a right to the dull season for some self-improvement and rest. Such a matter can easily be overdone on either side, but I will do my best work for the man who takes pleasure in my good.

### THE LATE W. B. BOLTON.

As we foreshadowed would be the case, a fortnight ago, it was humanly impossible for Mr. W. B. Bolton to recover from the disease of cancer from which he had been suffering for several months past, and he died on Friday morning, May 12. Only eight hours afterwards his mother was also removed by death, and she and her son were buried in the one grave on Tuesday last.

William Blanchard Bolton was born at York in the year 1848. It was in the month of September, 1864, that the collodio-bromide emulsion process, with which his name and that of the late Mr. B. J. Sayce were associated, was published in the pages of *THE BRITISH JOURNAL OF PHOTOGRAPHY*, so that, although still, comparatively speaking, a young man at the time of his death, he had been before the photographic world no less than thirty-five years. In the year 1865 his name figures in our *ALMANAC* as the Honorary Secretary of the Liverpool Amateur Photographic Association. With the exception of our esteemed friend, Mr. James Alexander Forrest, one of those originally associated with the Editorial direction of the *Liverpool and Manchester Photographic Journal*, we believe that all Bolton's Liverpool friends have passed away.

In the month of January, 1874, Bolton published in *THE BRITISH JOURNAL OF PHOTOGRAPHY* a washed-collodion emulsion process; and for several years considerable commercial success attended the method which owes its origin to him of removing all the soluble salts from the emulsion and adding an organifier. This amounted to an almost revolutionary improvement in the unwashed process of Sayce and Bolton, introduced ten years before; and, looking back, it must appear strange that so obvious an improvement should have escaped notice long.

For many years one of its most valued contributors, Bolton became Editor-in-chief of this *JOURNAL* on January 1, 1879, and occupied that position until the end of 1885, when the late Mr. J. Traill Taylor resumed his occupancy of the chair. During the years 1879-84 Bolton's writings and experiments on the preparation of gelatine emulsion were both valuable and voluminous, and there is no doubt that in the early days of the new process much useful knowledge was gained from what he published in these pages on the subject.

For several years past deafness and other causes obliged Mr. Bolton to live in the country and absent himself from photographic society meetings and so forth, so that he became a little out of touch with current photographic matters; but he retained his intellectual vigour almost to the very last, as a letter we received from him shortly before his death amply shows. In other circumstances Bolton might have filled a foremost place in photography to-day, and we are sure the news of his painful end will be learned with great regret by many of the old school. He leaves a widow, but no children.

### YORKSHIRE PHOTOGRAPHIC UNION.

A MEETING of delegates was held at the Leeds Institute, Coobridge-street, Leeds, on Thursday evening, May 11, the following gentlemen being present: Messrs Godfrey Bingley, P. Lund, J. Taylor, Dickinson, J. W. Holland, Hansworth, T. Heaps, H. W. Briggs, P. Sheard, T. W. Rhodes, J. C. Coultas, J. A. Ashby, and Ezra Clough, Hon. Secretary.

Mr. Percy Lund having been elected to the chair, the meeting received the report of the sub-committee as to the proposed excursion to Selby, and after some discussion they were empowered to carry out the necessary arrangements to make the visit a success. The date finally fixed for the excursion is Saturday, June 17 next.

As to the programme, the morning will be devoted to photographing the Abbey, and afterwards the members will proceed by special train to Cawood Castle, where the cameras will be busily employed obtaining pictures of the Castle and the river scenery, and, returning to Selby, dinner will be served at the Londesborough Arms Hotel at six o'clock.

The Secretary was instructed to obtain the collection of slides from societies and members of the Union for circulation, in accordance with the objects of the Union, during the coming winter sessions.

Messrs. Godfrey Bingley (Leeds P. S.), Alexander Keighley, F.R.P.S., Percy Lund (Bradford P. S.), and Percy Sheard (Batley P. S.), were unanimously appointed the official Judges of the Union.

The next meeting in connexion with the Union is to be held at Halifax, on June 22.

## Our Editorial Table.

### THE CUT-FILM SWALLOW CAMERA.

Marion & Co., Soho-square, W.

The leading features of this ingenious hand camera for taking cut films may be thus summarised:—

Its outside measurements are  $8\frac{1}{2} \times 6\frac{3}{4} \times 4\frac{1}{2}$ . It takes thirty quarter-plate flat films, without notches. Its weight loaded is 4 lbs. The lens is a single achromatic; it has three diaphragms. The camera is provided with two finders, one for upright and one for oblong pictures. It has an instantaneous shutter, with adjustment for time exposures. A carrying strap handle is placed at the top of the camera.

The user of the camera is advised, before inserting the sheaths in the camera, to see that the number 30 is shown in a small opening at the side. This is done by working the lever at the side of the camera to and fro until the number 30 appears. The films slide easily into the grooves of the sheaths. As the sheaths are filled, place the little projecting pins at the bottom of the sheath, on the runners on either side of the interior of the camera, and slide into place, back of sheath towards back of camera. The sheaths may be inserted in any order, with the exception of one sheath, which will be found to be extra thick and heavy. This sheath, which is easily recognisable by its weight, must be inserted last of all.

Its object is to receive the pressure of the spring on the door of the camera without bending. When all the sheaths are inserted, close the door of the camera, and the spring on the door will keep them in place.

To change the film, the following are the instructions: On the upper right-hand side of the camera will be found a small lever. Hold the camera in the left hand firmly, the front of the camera well downwards, as shown in the illustration. Rest the fingers of the right hand on the top of the camera, and the thumb on the top of the lever. Smartly press the lever down and round, so that it makes a circular movement from

pin to pin, then bring the lever back to its original position. The film will be heard to drop, and at the same time the number at the side of the camera will be found to have changed from 30 to 29, thus denoting that there are 29 more films left to expose. This number changes automatically every time a film is changed, the number indicating always the number of films left to be exposed. This changing of the film should be done immediately after each exposure; thus the films will be found to have moved in succession from the vertical position at the back of camera to a horizontal position at the bottom of camera.

The many admirable points in the Cut-film Swallow Camera should render it exceedingly popular.

### THE SIMPLEX CHANGING AND DEVELOPING TENT.

Manufactured by F. Beresford, 14, Bridge-road West, Battersea, S.W.

MR. BERESFORD has submitted to us the latest form of his changing and developing tent, which well deserves its description of "a model dark room, that can be erected or closed in one minute." It consists of a neat box containing the tent, &c., when closed, and it opens like a book and forms the foundation. Two light iron uprights and a crosspiece drop into sockets, and the fabric is drawn over this framework, and fastened underneath the box. It is fitted with a window of ruby medium, two sleeves, and a facepiece, which leaves the mouth free for breathing out-

side. The 'greatest freedom is given to the hands and head.' A sink, specially prepared to resist the action of chemicals, is fitted, large enough to hold three half-plate dishes. The remaining space is amply sufficient for dark slides, chemicals, water bottles, &c., whilst a movable india-rubber waste pipe is fitted to the sink. The measurements of the tent are: erected,  $20 \times 20 \times 20$ ; closed,  $20 \times 10 \times 8$ ; and its weight about six pounds. Either closed or open, it is exceedingly portable, and is very roomy or comfortable to change or develop in. Mr. Beresford has long been noted for the practicability of his developing and changing specialties, and the tent under notice is a really useful piece of apparatus, which should be greatly appreciated by travelling photographers. It is well made and cheap.

### BERESFORD'S RECTISCOPE.

THIS is a handy little prismatic instrument for enabling the photographer to view the inverted image the right way up. It may be used under the focussing cloth, and gives a brilliant image with perfect definition. The instrument may also be used as a focussing magnifier, a movable lens

being provided for that purpose. Used in this way, there is the advantage of viewing the magnified portion of the picture in its non-inverted position. The rectiscope will be appreciated by many who value the acme of convenience in focussing.

### GRIFFIN'S RAPID HYPO FIXER.

J. J. Griffin & Sons, 20-26, Sardinia-street, Lincoln's Inn-fields, W.C.

IN sending us a sample of this fixing agent, which is sent out in the convenient form of exceedingly fine pulverulence, Messrs. Griffin point out that it is suitable for plates, films, or lantern slides. It is unfortunate, they add, that the hypo crystals used in such large quantities for photographic purposes should be supplied, up to the present, in a form so unsatisfactory to the consumer, besides bringing little profit, if any, to the retailer. The crystals soon absorb moisture, are unpleasant to handle, dissolve with difficulty, are unequal in action, and to many, who often work in a hurry, are the cause of stains, spots, and unequal fixation. The Rapid hypo is introduced to permanently displace the crude hypo now sold. Besides its more expeditious fixing action—due to an exact degree of concentration—it clears and hardens the emulsion, destroys

etains, and contributes to permanency. The price has also been fixed so low that it is hardly more expensive than ordinary hypo and is undoubtedly far more economical in the long run.

Each box is waxed to exclude air, and contains two charges, separated by a cardboard disc. Thus amateurs who wish to fix only a few plates can do so, and leave the second charge for another occasion. Each charge makes ten ounces of fixer for plates.

We can speak from personal experience of the great convenience of using hypo in the form here mentioned, and have no doubt that many other photographers will appreciate their hypo in the state of fine powder, having all the features claimed for this.

*To Mountain, Castle, and Crag by an Ocean Route* is the title of a well-illustrated book issued by the Aberdeen Steam Navigation Company, describing a number of attractive Scotch tours by land and water.

## News and Notes.

**PHOTOGRAPHIC CLUB.**—Wednesday evening, May 24, at eight o'clock. Open Night.

**THE AUSTIN-EDWARDS MONTHLY FILM NEGATIVE COMPETITION.**—The prize camera for the current month has been awarded to Mr. W. B. Green, Grasmere, Gladstone-road, Watford, for his negative, *Primroses*.

A JOINT outing of the Borough Polytechnic and Cripplegate Institute Photographic Societies took place on Saturday last to St. Paul's Cray. Both Societies were well represented, and, favoured with fine weather, the innovation proved highly successful.

**THE DERBY EXHIBITION.**—Messrs. Byrne, of Richmond, write: "In your last issue you give a list of the names of those who have accepted the invitation to exhibit at the forthcoming Exhibition. In that list our name does not appear, although we accepted the invitation to exhibit frames."

**ROYAL JOURNEY TO THE NORTH POLE.**—H.R.H. the Duke of Abruzzi has just left Rome for Scandinavia for his expedition to the North Pole. It is calculated that the journey will occupy eighteen months, and will cost three million francs, of which one-fourth is provided by the King. Messrs. Adams & Co. have had the honour of supplying the expedition with photographic apparatus, including a Tella film camera.

**THE SANDELL "PERFECT" COMPETITIONS.**—The following are the results of the April competitions of Sandell Films and Plates, Limited: 10*l.* prize, Mr. C. Speight, Kettering; 5*l.* prize, Mr. F. W. Fielder, Guildford; 1*l.* prizes, Messrs. Julius A. Kay, Southampton; G. W. Morgan, Aberdeen; Arthur Waterall, Flixton; John H. Coath, Liskeard; Edwin Matthews, East Dulwich; the Rev. C. J. Metcalf, Ambleside; Messrs. H. R. Campion, Ely; William McClean, Belfast; S. M. Hibberd, Seaforth; and William Towell, Coventry.

MR. WILFRED EMERY writes: "I wish to thank you for your kind notice in last week's BRITISH JOURNAL OF PHOTOGRAPHY, and to draw your attention to a slight slip of the pen, but one which would create a very false impression. You describe me as *agent* for the folding "Apeks." Now, the word "Apek" is my special property, and applied to goods which I either make, or have specially made for me, or take especial trouble to push, so that the term *agent* might lead the trade to believe that the "Apek" trade mark belongs to some one else. I trust you will be able to correct this.

**THE WARWICK MONTHLY COMPETITION.**—The prize-winners in the Warwick Monthly Competition for May are as follows: 1*st* prize, 10*l.*, Mr. F. W. Fielder, Foxenden-road, Guildford, *Lady in Victorian Dress*; 2*nd* prize, 5*l.*, Mr. John M. Whitehead, George-street, Alva, N.B.; twenty prizes of 1*l.* each, Messrs. A. George, W. G. Elcombe, R. H. Beavan, C. Sordes Ellis, J. H. G. Ridley, J. Walker, Thomas Knox, Harold Baker, F. Whaley, Ernest Coath, Cecil D. Palmer, F. G. Dalby, H. E. Watkin, Albert Durn, Gus. Edwards, Charles Speight, G. Campbell Dickson, Ernest Oetzmann, Misses M. Craigie Halkett, and F. Yate-Lee.

**TRANSPARENT PAPER.**—There are several methods of rendering paper transparent. Coat white paper with a solution of Irish moss in water, to which a slight quantity of previously dissolved gelatine has been added. It should be applied hot to the paper. When colours are desired they must be transparent; they must be ground in varnish, and a stronger varnish is required than for opaque colours. A fine yellow may be produced by using yellow lake and red sienna. These make a warmer colour than the yellow lake alone. If cost is no objection, auramine may be used. For pale red, madder lakes should be employed, but for darker shades crimson lakes and scarlet cochineal lakes. The vivid geranium lake gives a magnificent shade, which, however, is not at all fast in sunlight. The most translucent blue will always be Berlin blue. For purple, madder purple is the most reliable colour, but possesses little gloss. Luminous effects can be obtained with the assistance of aniline colours, but these are only of little permanence in transparencies. Light transparent green is hardly available. Recourse has to be taken to mixing Berlin blue with yellow lake or red sienna. Green chromic oxide may be used if its sober, cool tone has no disturbing influence. Almost all brown colouring bodies give transparent colours, but the most useful are madder lakes and burnt umber. Grey is produced by mixing purple-tone colours with suitable brown, but a grey colour hardly ever occurs in transparent prints. Liquid siccativ must always be added to the colours, otherwise the drying will occupy too much time. After the drying, the paper must be varnished on both sides. For this purpose a well-covering, quickly drying, colourless, not-too-thick varnish must be used, which is elastic enough not to crack nor to break in bending.

A NEW method of marking glasses of spirit levels and other instruments has been devised by a Connecticut concern making levels and other instruments. The usual way of marking glasses is to scratch lines on the surface of the glass, but the skin of the glass is thus weakened and the glass itself made very liable to fracture. In the new process, by fusing the glass at the mark and incorporating with it minute particles of metal, a coloured line is obtained. The metal is imbedded in and enclosed by the glass, which effectually protects it. In fact, the glass at the grooves has been so strengthened that it will break first at some other point. In addition, the line is absolutely indelible and permanent, and is sharp and well defined. This is effected by bringing the spirit tube up to an iron disc rotated at a velocity of about 2500 revolutions per minute. The frictional heat generated practically fuses the glass at the point of contact with the wheel, and in this fused portion fine particles of iron given off by the wheel are imbedded. A microscopical examination of the line proves this to be true. An actual mechanical union of iron and glass is the result.

**APPARATUS FOR UTILISING THE SUN'S RAYS.**—It is well understood that the great desideratum for the successful working of apparatus dependent upon the sun's heat is that the sun should shine uninterruptedly upon it through air devoid of all moisture. With this in view, a machine is proposed (says *Le Monde Scientifique*) for realising this requisite by storing the sun's heat. This consists of a large conically shaped reflector of highly burnished copper, which has located in its centre a boiler made of heavy glass. The heat obtained is stored in a reservoir of sand, surrounded by a heavy woollen covering, which is said to effectually prevent the heat from radiating, while retaining it in the sand until it is required; and the reflector may be moved backward or forward in a horizontal plane by means of a lever, while a pair of cog wheels running in a toothed rack enable it to be elevated or depressed. In operation, the conically shaped funnel is set at the proper angle facing the sun, and the heat converging upon the reflector from all directions is transmitted to the reservoir of sand; engines and dynamos may thus be operated under this arrangement by simply drawing out the heat thus stored up.

## Patent News.

THE following applications for Patents were made between May 1 and May 6, 1899:—

**CINEMATOGRAPHS.**—No. 9552. "Improvements in Cinematographs." J. PESCHER and G. H. CHARD.

**CHANGING BACKS.**—No. 9574. "Improvements in Changing Backs or Magazines for Films, Plates, or the like, to be exposed in Photographic Cameras." M. NIELL and J. STUART.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
22.....	Borough Polytechnic .....	Excursion: Burnham Beeches. Leader, F. W. Bannister.
22.....	Bradford Photo. Society .....	Open Night.
22.....	Kingston-on-Thames .....	Excursion: Shere. Leader, A. E. Smith.
23.....	Hackney .....	Lantern Evening: A Trip on a Norfolk River.
23.....	Ludlow .....	Excursion: Penbridge, Herefordshire.
23.....	Royal Photographic Society .....	Corea. Mrs. Isabella Bishop, F.R.G.S.
24.....	London and Provincial .....	Important Photographic Problems that Require Investigation. Herbert J. Starnes.
24.....	Photographic Club .....	Open Night.
25-31 .....	Ashton-under-Lyne .....	Exhibition of Loan Collection of Pictures Toning Gelatine Emulsion Paper. W. A. Nash.
25.....	Oldham .....	Conversational Meeting.
26.....	Croydon Microscopical .....	Excursion: Warwick. Leader, Harold Baker.
27.....	Birmingham Photo. Society ..	Excursion: Storeton and Bebington. Leader, G. A. Carruthers.
27.....	Liverpool Amateur .....	

### ROYAL PHOTOGRAPHIC SOCIETY.

MAY 16.—Photo-mechanical meeting.—The Right Hon. the Earl of Crawford, K.T., F.R.S. (President), in the chair.

#### COLOURS IN PLATINUM PRINTS.

Mr. J. C. H. WALLSGROVE forwarded a platinotype print of some flowers, the image being partly in brown and partly in black, together with a note explaining the method by which he obtained "three distinct colourings—black, white, and brown—direct in one printing from a single negative, without further treatment of the prints." The process appeared to consist in over-exposing platinum paper under a negative possessing full contrast, the variation in colour being due to solarisation.

#### IRREGULAR GRAINED SCREENS.

Mr. DAVIS (representing Messrs. E. S. Hunter & Co.) exhibited specimens of the "Haas" grained screens, with specimen prints, in black and white and in three colours, from negatives made with the screens.

The PRESIDENT, Colonel WATERHOUSE, and several members spoke very highly of the excellence of the results shown, and of the great uniformity in the distribution of the grain of the screens, several of which were passed round for examination.

## COMING EVENTS. THE SOCIETY'S NEW HOME.

It was announced that on Tuesday, June 20, the President and Council would receive the members of the Society, and of affiliated societies, at No. 66, Russell-square, and the President expressed the earnest hope that that occasion would be the inauguration of a long and prosperous career for the Society. The arrangements in the mean time are as follows:—May 28, Technical Meeting. "Korea," by Mrs. Isabella Bishop. June 13, Ordinary Meeting. "Acetylene," by Professor Vivian B. Lewes.

## LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 11.—Mr. T. E. FRESHWATER opened a discussion upon the subject of Modern Photographic Lenses, and showed one of the smallest of these, the Zeiss Planar, Series A, No. 2 35 mm. focus, 12 mm. diameter. He exhibited some photographs of very curious spiders that he had just made with this instrument, working at full aperture, in conjunction with his photomicrographic apparatus, and in which the definition and crispness of the hair left but little to be desired. He next passed round two or three of the new stigmatic lenses of Messrs. J. H. Dallmeyer, Limited, and from the remarks made by the meeting it appeared that this series of lenses was very much in favour.

Mr. J. E. Hodd brought up several lenses, including the convertible Ross-Satz, Series IIIA, working at 7.5; the Cooke Lens, Series V; Voigtlander, Series III; and Wray's Platystigmat.

Mr. F. C. Kellow showed some photographs made with a hand camera, fitted with the Ross-Zeiss, Series III Lens, of 3½ focus.

Mr. PHILIP EVERITT had several lenses of various makers, amongst which were Steinheil's orthostigmat, Series II, and Dr. Schroeder's concentric lens, which, he said, was the first to employ the new glass in its construction. The same speaker had had a Ross-Zeiss fitted to his hand camera, the advantage of the lens being that it could be also used with a 7½×5 camera; moreover, used singly, the focus of the back combination was nine inches and the front eleven and a half inches, with no marginal distortion.

Many other lenses were brought forward and shown, and a long discussion ensued upon their various qualities and peculiarities.

**Croydon Camera Club.**—A comparison of hand cameras formed the staple on Wednesday, the 10th inst., when a considerable attendance of members, and a good show of various types of the hand camera, ensued. The PRESIDENT described a cartridge Kodak, pointing out both its strong and weak points, this wholesome precedent being generally followed. Mr. CHADWICK TAYLOR spoke up for the Frena, Mr. PACKHAM doing the same for his Tella, which is a remarkably compact and ingenious instrument, carrying fifty films. Mr. BEN EDWARDS explained a Verascope, and showed stereoscopic results obtained with it. Mr. Willeocks exhibited a Gear model hand camera, made to use with lenses of foci from three to ten and a half inches, rising front, vertical swing, focussing screen, T.-P. shutter, four double backs, cost, without lens, 41. 8s. 6d. This was considered a capital type of all-round hand camera for serious work. Mr. Rogers was represented by the Bruno, which is only less convenient than the foregoing on account of its greater size. Mr. J. Smith showed the Dresser pattern hand camera (made by Hirst). Mr. CARR claimed approval for the Yale, a newly contrived compact instrument working on the bag-changing system. Twenty-four films, or twelve plates, are usable at each change. It was thought good value at 54. 11s. Mr. PEARCE spoke of his Rover hand camera, which has been his companion over many thousands of miles. In a humorous speech he dwelt on its imperfections, which, he said, had rather endeared him to the camera in question than otherwise. Mr. Mote brought forward a Munro pocket camera. Messrs. Pym, Noaks, and others also showed cameras, including Shew's Eclipse, now well known for its utility and portability. At the conclusion of the main subject, Mr. BEN EDWARDS described a new light-filter for use with isochromatic plates. In the subsequent discussion Mr. CHADWICK TAYLOR stated that a certain make of plate claiming to be isochromatic gave no better results than an ordinary plate tested against it, using in each case a yellow screen. Mr. PACKHAM stated that not all plates possessed the degree of isochromaticism indicated by the labels on the box. But the best makes of isochromatic plates, such as Edwards's, were, he found, from their action in microscopical photography, much in advance of ordinary plates for full-colour rendering. An excursion, at short notice, was held on Saturday, and proceeded, in charge of Mr. S. H. Wratten, for a photographic ramble *via* Croyham Hurst to Addington Hills.

**Croydon Microscopical and Natural History Club (Photographic Section).**—On Friday evening last a circulating lecture on

## HAND-CAMERA WORK, WITH A VIEW TO ENLARGEMENT,

by Mr. J. H. Gear, was read. If it is permissible to criticise these lectures, we would say with regard to this one it struck us that, while it was a fairly good exposition of photography generally, treated in a somewhat elementary manner, the main subject as indicated by the title was rather lost sight of, for instance, what kind of negative was most suitable for enlargements, and the class of negative which was unsuitable, pointing out how to obtain the best kind, which would depend rather on development than exposure, and illustrating these points by the negatives themselves as well as lantern slides. On one or two points we should not feel disposed to agree with the author, and some of the slides, we should think, could hardly have been made from negatives produced strictly by the hand camera, but by a hand camera used as a stand camera, judging, that is, from the exposures which must have been necessary. In saying this we do not for one moment wish to deny the capability of those gentlemen who produce these circulating lectures, that is too well known and recognised to need any defence, but rather to the treatment of the subjects by some of them. Of course, if the subject must be treated in an elementary manner, for the benefit of certain members of the

societies receiving the lectures, then it seems a reflection on certain other members, who could, and perhaps ought to, render the necessary information to their less experienced brethren. It is like paying some one else to do work that one could do equally well oneself. If that is not the object, then we would suggest that the lectures should be less elementary, and give us a little more of the benefit to be derived from the experience of masters of the art.

**Leeds Photographic Society.**—On Tuesday evening, May 9, Mr. Frank M. Sutcliffe, of Whitby, was to have delivered his lecture on

## SOME EXPOSURES

to the members of this Society, but, to the regret of every one present, the PRESIDENT (Mr. Godfrey Bingley) announced that Mr. Sutcliffe was unfortunately laid up at home in bed, and forbidden to come to Leeds by his doctor. The lecturer had, however, done the next best thing to coming himself, and that was to forward his manuscript, which he would read to them, and he asked for the indulgence of the audience if, in doing so, the lecture did not run as smoothly as it would otherwise have done. In the course of the paper the writer said the Americans had a saying, "Be sure you are right; then go ahead," and that was just what every photographer ought to remember to do, and, when we had found a suitable spot, there was nothing to stop us going ahead when our nerves and instinct show us we are right. If there was one thing photographers had to be proud of, it was that they had made evident the beauty of the heavens. Fifty years ago Ruskin told the people how much they lost by not looking at an ordinary sky and the clouds which passed over it, but it had remained for photographers to demonstrate, by practical examples, the unparalleled beauty of cloud forms. There was no photographer worthy of being called such who had not taken as many photographs of the clouds as the earth. Sometimes, when taken over the sea, they formed a not inharmonious whole. Stock negatives of clouds came in very useful. He could well remember the time when all photographs which were considered good had perfectly white skies, and if they did not print white the negative had to be painted to make them so. If there were any photographers there that night who had not gone in for taking the sun, it might save them a headache if he told them to provide themselves with a smoked glass to watch the clouds through. In many instruction books the student was advised to go over a district without his camera, make up his mind when the sun would be in the best position, and go next day and take each view as decided. This advice always seemed very foolish to him, as anything worth photographing was not likely to happen twice. The lecture was illustrated by as fine a series of slides as it has been our lot to see for some time, and comprised almost every class of subject, but principally scenes of Whitby and the fisher folk "snapped" in their native haunts. The paper, which occupied an hour in reading, was a very interesting one, and full of practical hints to photographers. At the conclusion of the lecture the SECRETARY announced that Messrs. T. H. Oxley and W. S. Crowther had been elected members of the Society.

## Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* We do not undertake responsibility for the opinions expressed by our correspondents.

## SPOTS ON PRINTS.

To the Editors.

GENTLEMEN,—Having noticed, in a recent issue of the JOURNAL, queries respecting the above, it may be worth while to call attention to the cause of this annoyance, which gave me considerable trouble some time since. After many fruitless efforts to discover cause for small brown spots, apparently sprinkled over the prints (generally the cabinets and cartes), I eventually found it to proceed from minute particles of iron distributed over the mounting table by revolutions of the roller squeezes I had then in use. This conclusion is supported by the fact of continual wearing away of pivots of roller when in use; also by total disappearance of spots from the time of its being put aside.—I am, yours, &c.,

Rosebank Studio, Winchester, May 16, 1899.

W. PALMER.

## A SOCIETY FOR PHOTOGRAPHIC PRINTERS.

To the Editors.

GENTLEMEN,—It would be impossible to correct all the statements made by Mr. Randall, as space would not allow of it. There seems to be but one way in which Mr. Randall views the matter, and that is through the already organized systems which exist. What I want to do is this, keep in view the original statements.

1st. I hold that photographic printers, or, for the matter of that, any photographic employes, can not be induced to join any of our trades unions, because it would simply mean ruin to them. They know that to be compelled to accept only a union rate of wage would be to stand on one side and allow others to take their places. Such is the present condition of things, and I think Mr. Randall admits this. It is, then, a question of what can be done, not what we should like.

2nd. Mr. Randall says I attempted "to maintain two lines of conduct which are contradictory" because I advocate a printers' union, which, as he (Mr. Randall) says, could not recognise the right of a member to

work for 11. when 21. would be a fair wage, and that the assistant cannot afford to join a union because he must accept what he can get, in which case the union would be quite useless. Now, if I misunderstand your able correspondent, I shall be pleased to stand corrected.

If Mr. Randall will refer to the first letter on this subject (April 21), and kindly read my last paragraph in that letter, he will see that my intention was not to set a wage limit (although this would come in due course with sufficient support and strength of members), but to have a general centre, where members could not only mutually improve themselves in their work, but where grievances could be ventilated, where printers could be classified, where the "trade" could apply for a man, and then we should have a printer remain a printer, as we have a plumber or a carpenter in the building trade remaining such. Let me again remind your readers that no assistant in photography can at present join a restrictive union, and I am afraid that, unless a society be formed on some such grounds as indicated, then no society will exist.

I should feel glad if some other correspondents would be good enough to express their opinions on this subject. In the mean time I am sure we are pleased with Mr. Randall's very comprehensive remarks, which he has so ably made, upon unionism.—I am, yours, &c.,

F. G. WILLATT.

101A, Fulham Palace-road, Hammersmith, W., May 15, 1899.

### THE RECENT FLASHLIGHT EXPLOSION.

To the Editors:

GENTLEMEN,—With reference to my recent accident, I should like to say it was in no way due to Maloni's four-jet lamp. The facts were as follows: In taking a flashlight photograph, my usual glass bottle being empty, I used a piece of cardboard to take the powder from the tin containing about two ounces of magnesium powder. In filling one cup, the cardboard caught in the jet. After blowing it out, and waiting for the heat to subside, I was in the act of taking more powder when the explosion occurred. I have used the lamp with much success, and was quite satisfied with it, and distinctly wish it to be understood that no blame whatever is attached to it.—I am, yours, &c., W. C. HARVEY.

124, High-street, Gosport, May 15, 1899.

### AN ADDRESS WANTED.

To the Editors.

GENTLEMEN,—Can you, or any of your readers, kindly give me the address of Mr. S. Wing, the patentee of Ferrottype Photo Apparatus, or the firm in England or America who make his apparatus? I have one of his patent machines, with some parts missing, which I would like to replace.

Hoping to be excused for taking up your valuable space, I am, yours, &c., A. W. ANDREE.

Hoptown Studio, Colombo, April 27, 1899.

[Some reader may perhaps be able to supply the address.—Eds.]

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

T. REVERLEY, Market-place, Wantage.—Photograph of men accused of the Horwell (Berks) murder, handcuffed to policemen.

J. LOWERY, 47, Newgate-street, Bishop Auckland.—Photograph of football team, Bishop Auckland team, winners of the Durham Cup and Northern League Championship, 1898-9.

T. FRASER and others.—In our next.

E. WILLIAMS.—Thanks for your letter.

GWYNFFA.—Possibly a dilute solution of citric acid would remove the stains.

H. RICKETTS.—If the photographs are really copyright, and have been duly registered at Stationers' Hall, you would run the risk of an action for infringement.

T. KING.—With the photograph as it stands there is no serious fault. It is, perhaps, slightly under exposed, and it might have been better if you had chosen the point of view a little more to the left; but otherwise it is very good.

LEGAL.—This is a matter into which we regret we cannot enter. Your best adviser would be a patent agent, although, having regard to the smallness of the matter and the fact that the larger proportion of so-called "photographic patents" run a serious risk of being declared invalid in the Courts, it would be very doubtful policy on your part to take legal proceedings. It might be a case of throwing good money after bad.

THE PROJECTED COPYRIGHT ACT.—C. R. You seem to be under a misapprehension. The new Bill has not become law, and it is possible that it will not be so without some amendments. Even if it were law now, it would not help you, and it would be very undesirable that it should. So would any law that would countenance piracy, and what you propose would be decided piracy in a disguised form.

DRYING COLLODIO-CHLORIDE PRINTS.—R. E. DAVEY writes: "I am told that collodio-chloride prints may be dried by blotting them off between blotting-paper. My experience has been entirely confined to P.O.P., which cannot be treated in that way, and I often require to dry prints in a hurry. Please say if I am correctly informed, because, if so, C.C. paper would sometimes be a boon to me!"—Yes, collodio-chloride paper may be blotted off, and the drying completed before the fire without injury, just the same as albumen prints may be.

COMBINATION PRINTING.—GROUP says: "I have taken a 12×10 group in which two spaces have been left for printing in portraits of gentlemen not able to be present when group was taken. I have good cabinet photographs, which I am about to reduce to exact size of those in the group, and should be glad to know which you consider the best way to print them in so as to show no join. I should require to print about twenty copies, and, as I have never done anything of the kind before, should like your advice."—An article on the subject, which will just meet our correspondent's case, will be found on p. 18 of our volume for 1895.

SPOTTING AND MOUNTING.—W. J. says: "I shall be glad if you will kindly inform me—1. What is the best thing to use to 'spot' prints to be enamelled that will not leave the picture when in water or gelatine? 2. Is there any method to mount an enamelled print so as to make the whole surface of the block adhere to the mount without injuring the polish of the photograph?"—1. There are special colours supplied for the purpose. Mr. Rudowsky, 22, Coleman-street, E.C., supplies them, so do most of the large dealers. 2. Yes, by pasting one or two thicknesses of paper on the prints when they are squeezed on the glass. When dry and stripped off, they may be mounted in the usual way.

GELATINE FOR MOUNTING PURPOSES.—D. McLEOD says: "I have recently been trying gelatine for mounting my prints, and I have used both Coignet's and Heinrich's, but my mounters say they cannot get on at all with it, as, before they can even cover a cabinet print, the solution sets. With the larger sizes the case is still worse. Can you tell me a remedy, as I often see that gelatine is recommended in preference to any other mountant?"—The cause of the trouble is the unsuitability of the gelatine for the purpose. What is required is one with slower setting properties, such as Nelson's No. 2 soluble, or Cox's soup gelatine. These, when used dilute, enable large surfaces to be coated before the mountant gelatinises.

VALUE OF LENSES.—GVALIA says: "A friend of mine showed me some lenses and wooden cameras, which he wanted to sell me. The lenses are from the following firms: One single landscape, one *carte-de-visite* portrait lens, by T. C. Ponting, Bristol, engraved on both lenses; also one portrait lens, *carte-de-visite*, by Jabez Hughes, London. This one is registered No. 4012. We had two wooden cameras, 5×4 and 7½×5½, if I am sure. What would you estimate the lot? Could I use the lens with Lancaster whole-plate camera?"—The lenses can, of course, be used on any camera. Neither of those whose names they bear were makers of lenses. They are of French make, though probably good, but, like the cameras, are of little market value, being very antiquated.

RESIDUES.—TONING BATH says: "Will you please inform me if the gold and silver from used toning baths can be saved and the method used to do so? I have occasion to use about five toning baths in a week, and always use a new bath for each batch of prints, of about sixteen cabinets. I use separate toning and fixing, and tone without previous washing, and have always thrown the used baths away, and should like to know if the gold and silver can be obtained from them."—The silver and gold can be saved, and the method of doing so has often been described in the JOURNAL; but, if gelatino-chloride paper be used, and the toning bath be well exhausted of its gold in toning, we doubt the economy of saving the residues from such a small consumption of paper.

MEALY PRINTS.—W. & B. write: "We have always used P.O.P., but, finding that so many of our prints turn yellow, we have recently been trying albumenised paper, both ready-sensitised and of our printer's own sensitising, but all our prints turn out mealy. We have used the acetate toning bath, made as follows: Acetate of soda, 1 drachm; water, 16 ounces; chloride of gold (Johnson's), 2 grains. We have used the bath directly it was mixed, also after keeping it an hour and up to three hours, but in all cases the prints turn out mealy. With the carbonate bath we get on all right, but we do not like the colours. Where are we wrong?"—In not keeping the toning bath long enough before using it. The acetate bath requires to be kept for at least twenty-four hours before it is used, or it will yield mealy prints.

ACETYLENE.—Acetylene, like the cinematograph, seems to be heavily handicapped. By an Order in Council, some time ago, calcium carbide was made petroleum within the meaning of the Act. Last week a London firm were proceeded against at the Thames Police Court, for permitting a vessel carrying forty drums of carbide of calcium to be navigated in a manner contrary to the by-laws made by the Conservators under the Petroleum Acts of 1871 and 1879 and an Order in Council of 1897. But the magistrate held that the carbide was not within the Act, and, if the Conservators thought it ought to be, they should pass a by-law dealing with it. The case was adjourned *sine die*, to enable the point to be considered. What with the restriction regarding the conveyance and storage of the carbide, the prospect of the acetylene light is not altogether promising in this country.

## EX CATHEDRA.

JUST about this time of year the receipt of the *Handbook of Imperial Plates and Papers*, issued by the Imperial Dry Plate Company, Limited of Cricklewood, N.W., warns us to look to the Company for something practical and useful in the way of photographic information, and our expectations are again realised in the 1899 *Handbook* now before us. This is sent free of charge to applicants, and we may promise them that the book is well worth asking for. Mr. Gear writes on "Bromide Printing," and Rev. F. C. Lambert on "Errors in Exposure and Development and how to Recognise Them." Illustrating this paper is a set of nine half-tone reproductions from faulty and correct negatives, five minutes' study of which is an education in itself. It is one of the most useful and instructive papers we have recently read. The *Handbook* has about a dozen half-tone illustrations made from negatives on Imperial plates, which need no higher testimonial than the good qualities of these results. A table of percentage solutions, formulae, &c., are also included in the *Handbook*, which is only to be seen to be assured of the highest appreciation.

A RECENTLY published specification for an improved photographic developer is that of Herr Julius Hauff, whose invention relates to the "application of the chlorine, bromine, and iodine substitution products of hydroquinone, hydrotoluquinone, pyrocatechin, pyrogallols,  $\alpha$ -hydronaphtoquinone,  $\beta$ -hydronaphtoquinone for developing photographic pictures.

"For this purpose he employs halogen substitution products of hydroquinone, hydrotoluquinone pyrocatechin, pyrogallols, and hydronaphtoquinones for the development of photographic pictures. These products are distinguished by the fact that they develop quickly and very powerfully and are only in the slightest degree affected by the temperature. They are thus capable of excellent service in instantaneous photography and in the studio or laboratory. The halogen products of substitution are as follows:—

Water .....	100 cm.
Monochlorhydroquinone .....	1 gramme.
Crystallised sulphite of sodium ...	8 grammes.
Potash or calcined soda .....	4 "
Bromide of potassium (1 : 10).....	10 to 20 drops."

\* \* \*

WE are informed that the Derby Corporation Photographic Exhibition will be opened on Tuesday evening, June 6, by the Mayor, and that there will be a *conversazione* to which he will invite the members of the Corporation and the Derby Photographic Society.

\* \* \*

A MEETING of the Röntgen Society will be held on June 30, 8.0 p.m., at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Mr. C. W. Mansell Moullin, F.R.C.S. A paper will be read by Mr. A. W. Isenthal, "Short notes on the Wehnelt Electrolytic Break." Mr. H. W. Cox will read some notes on the same subject. Mr. Apps and Mr. Wilson Noble will also speak. The apparatus will be demonstrated. Members who have worked with this Break are specially invited to attend and join in the discussion.

\* \* \*

THOSE of our readers who, at one time or another, have interested themselves in the Photographers' Benevolent Association may like to know that the fund of 300*l.*, which remained when the Association ceased its official existence, is in process of comparatively rapid extinction. With the approval of the

Registrar of Friendly Societies, the Photographic Club appointed a committee to administer the fund, which is being distributed among suitable applicants, of which, of course, there is no lack. The secretarial work of the Committee, which is very considerable, as that body meets weekly, is being performed by Mr. H. Vivian Hyde, to whom special recognition is due for the able manner in which he is filling a thankless office. The total disappearance of the Photographers' Benevolent Committee cannot long be delayed, and when the word "finis" is appended to its labours there will have been closed a chapter of history which reflects little credit on professional photographers and their assistants.

\* \* \*

PRESSURE of journalistic work prevented us from attending the funeral of the late Mr. W. B. Bolton on Tuesday in last week, but on the following Thursday we made our way to the pretty little village of Silsoe, in Bedfordshire, and saw the wreath-covered grave in which the remains of our late friend were laid only a few hours before. The churchyard, which contains all that is left of one who in past years contributed many important stones to the elegant edifice of modern photography, is situated at the gates of one of Earl Cowper's seats, Wrest Park. It will be learned with satisfaction that so much was Mr. Bolton liked in the village that business was entirely suspended during his funeral.

\* \* \*

WE have received from the Directors of the Crystal Palace the programme of general arrangements for the season 1899. It will be remembered that last year and the year before two great photographic exhibitions were held at the Palace. There appears to be nothing of special interest to photographers included in this year's programme; nevertheless, a glance through the latter shows that the Directors have included a great number of very attractive items, and it is to be hoped that the efforts being made this year to strengthen the hold of the beautiful Sydenham glass house, and its delightful grounds, upon popular favour, will meet with success.

\* \* \*

THE first number of the second volume of the *Birmingham Magazine of Arts and Industries*, published at 57, St. Paul's-square, Birmingham, has reached us. It contains fifty-five illustrations in half-tone, including one in three colours of a painting by Mr. Ormond E. Gollins. The aim of the *Birmingham Magazine* seems to be to represent all phases of local art and industry in their best aspects, and the editor appears to have a particularly warm corner in his heart for photography, as he has included a photographic survey and gives reproductions of many photographs. The *Birmingham Magazine* is full of interest and beauty, and we wish it a long career.

## COLOUR FACTS AND FALLACIES.

### II.

FROM the pile of Bennetto literature to which we referred a fortnight ago we have had no little difficulty in selecting such materials as may bear directly on the validity or otherwise of that gentleman's extraordinarily extravagant claims; but, if the sifting process has not been so easy as a busy editor could desire, it has brought with it the compensation of a little

genuine amusement. Indeed, if we could afford space to print the whole mass of nonsense penned by the ignorant journalistic and other friends of a great discoverer, who has still to prove that he has made any discovery at all, the extracts, seen by the light of recent developments, could hardly fail to excite pity and laughter in about equal proportions.

Two dates are of first-rate importance when we come to examine Mr. Bennetto's claims. In this JOURNAL of July 31, 1896 (p. 482), we printed the notable announcement that, "after seven years of patient investigation, our townsman, Mr. Wallace Bennetto, of Newquay, has attained what at one time appeared to be an unrealisable dream, viz., photography in colours of nature by *purely* photographic means. The results by this process are . . . , &c. Several leading scientists and distinguished persons have seen the results, and have declared them marvellous. . . . We congratulate Mr. Bennetto on having discovered the long-sought-for Philosopher's Stone of photography. . . . Mr. Bennetto intends to give an exhibition at Newquay before the season is over." We took these sentences from a little Newquay publication, to which for months afterwards Mr. Bennetto and ourselves made copious contributions on the subject of colour photography, and there is consequently no reason to doubt that the quotation represents what Mr. Bennetto said about his process and the claims he made for it.

From July 1896 let us whisk the reader to January 1899. In the first number of our volume for this year we again quote from an interview with Mr. Bennetto, this time with a Plymouth journalist. In that interview, after politely accusing us of misrepresenting his three-colour process in pigmented carbon, which we published from his own description last November, he goes on to say that he could have completely upset every one of our statements, but had decided to adopt another course, viz., to give a lecture and demonstration in Newquay. So far, not only has he not attempted to upset our statements, but the promised demonstration has not been given. Mr. Bennetto is very frequently going to do something which unfortunately invariably stops short of the stage of accomplishment. Finally, in the interview from which we have quoted, Mr. Bennetto makes it clear, after two and a half years' hesitation, that it is by means of three-colour carbon transparencies or prints that he claims to have solved the problem—"what at one time appeared to be an unrealisable dream, viz., photography in colours of nature by *purely* photographic means" (*vide ut supra*). How quaint it sounds to be told that three-coloured carbon prints or transparencies were once, in Mr. Bennetto's ideas, an unrealisable dream, when it stands on record that the process was worked out by Du Hauron in 1869—thirty years ago!

While in this article it is strictly our aim to examine Mr. Bennetto's remarkable claims by the evidence of their accomplishment with which he himself has supplied us, it is, perhaps, convenient that we should give the general reader who merely devotes casual attention to the subject of photography in colours some little idea or definition of the terms "photography in natural colours" and "colour photography" as both or either might be taken to apply to the work of Mr. Bennetto.

Both in these pages and in those of our ALMANAC we have more than once made pointed reference to a lecture given at Oxford, two years ago, on "The Scientific Requirements of Colour Photography," by Captain W. de W. Abney, unquestionably the highest living authority on the subject. In

the very first paragraph of the lecture the distinguished author tells us that colour photography and photography in natural colours are two distinct methods of arriving at the same end, viz., the production of a picture of objects in the same colours as they appear to the eye. Any feasible theory of colour vision lends itself to the success of colour photography, whilst it requires no theory to take a photograph in natural colours.

A glance at these definitions, the philosophy of which it is hardly possible to challenge, tells the reader at once how he may classify the different colour processes that have been brought to notice from time to time. The various three-colour processes in general, and those of F. E. Ives and Du Hauron in particular clearly come under the designation of colour photography, because they rely primarily upon the application of a theory of colour vision for their successful working out; on the other hand, the Lippmann interferential process; the Becquerel experiments on silver chloride; the Carey Lea experiments in the production of coloured photo-salts are direct processes, i.e., they "rely upon the simple act of light," and thus give results in "natural" colouring as distinguished from those which rely upon indirect methods of producing colour in the final results.

Now, it will be apparent from the foregoing that Mr. Bennetto's coloured carbon transparencies or prints are not produced by simple means, that is to say, they are indirectly obtained results, and consequently they are not natural colour photographs. If we may accept Captain Abney as an authority—and we know of none higher—Mr. John Wallace Bennetto's claim to have "attained the unrealisable dream and to have solved the problem of photography in the colours of nature by *purely* (i.e., direct) photographic means" is not worth a moment's consideration. It ought never to have been made; and only an ignoramus would any longer pay the slightest attention to it.

So much for the unfortunate claim to have solved a problem which still defies solution. But we have by no means finished with this claimant's indefensible pretensions. Still adhering to Abney's definition, it is clear that a three-colour carbon process on glass or paper ranks itself as an indirect or colour-photography process whose novelty, at this stage, can hardly extend beyond points of detail; in other words, experimentalists in three-colour work to-day are simply confronted by the minor problems of practice; the "discoverers" were the great masters of theory—Young and Helmholtz, Clerk-Maxwell, König, Abney, &c. Not even Ives, whose three-colour achievements far transcend those of any living photographer, allows himself the title of "discoverer," or makes large claims similar to those with which the name of Mr. Bennetto is associated. As between the latter gentleman and Mr. Ives on questions of three-colour theory and practice it would be cruel to make any comparison.

We have reserved till the last the severest commentary that can possibly be made on Mr. Bennetto's claims, and this issues out of the negative statements which that gentleman uttered about his process nearly three years ago. In one place we are told there is "no colouring, no dyeing, no staining, *all* the colours being obtained by photographic means alone; they were pure and simple natural colours." Again: "Accepting his assurance that no stains, dyes, or pigments are used." Yet again: "He has assured me that no pigment, dyes, or colouring matter of any kind was used." These statements were made by Mr. Bennetto to gentlemen who saw his results, and we have them both in print and in writing!

*No stains; no dyes; no pigments; no colouring matter of any kind!!!* On top of these amazing statements, which we have all along carefully held in reserve, Mr. Bennetto at last publishes details of the process that has "solved the problem," &c. (see this JOURNAL, December 2, 1898). Will it be believed, to quote his own words, that, "In order to produce the positives, I proceed as follows: I first prepare three pigments, a red (such as scarlet or vermillion), a blue (such as cobalt), and a yellow (such as chrome yellow), grinding them very fine and mixing with gelatine or other vehicle. . . . sensitising these bands with bichromate of potash," &c.—carbon printing with coloured pigments, in fact!!

Surely nobody but the veriest dunce, after the absolute destruction of every single one of the very weighty claims Mr. Bennetto has made and entirely failed to sustain, could accuse us of "injustice" towards his "process" (*sic*)! We should hope indeed, for the credit of photographic journalism, that after this exposure none of our contemporaries will allow themselves to be misled any longer in this matter. The Bennetto process has been thoroughly found out at last, and should at once be allowed to join the many other colour fiascos that preceded it.

#### NEGATIVES FOR ENLARGING FROM.

At the last meeting of the Photographic Section of the Croydon Microscopical and Natural History Club, a circulating lecture by Mr. J. H. Gear, on hand-camera work with a view to enlargement, was read. The report of the meeting supplied to us complains of the elementary character of the lecture, and that the main subject, as indicated by the title, was rather lost sight of, "for instance, what kind of negative was most suitable for enlargements, and the class of negative which was unsuitable, pointing out how to obtain the best kind." With reference to the elementary nature of these lectures, the report says: "Of course, if the subject *must* be treated in an elementary way for the benefit of certain members of the societies receiving the lectures, then it seem a reflection on certain other members, who could, and perhaps ought to, render the necessary information to their less experienced brethren. It is like paying some one else to do work that one could do equally well oneself." By the way, these remarks quite sustain others we have heard expressed of the exceedingly elementary and textbook character of some of these circulating lectures, and that they ought to be something more than what the veriest tyro is already familiar with.

Now, the question put in the report—and it is not an unimportant one—as to what is the best negative for enlargements, and what is the most unsuitable, it may be explained, depends very much upon the process by which the enlargement is to be made. This subject brings to mind many queries we have to answer through our Correspondence column. For example, the writers often complain that they are unable to obtain good enlargements from negatives that yield good direct prints. The term "direct prints" often means nothing in this case, for it is, or should be, well known that the kind of negative that is best suited for giving good vigorous prints on albumen paper, platinotype, or the carbon process, is not that best adapted for the gelatine papers, or for developed prints on bromide paper. In the same way the negatives that are the most desirable for enlarging from direct on bromide paper are not the easiest

ones to deal with in making enlarged negatives for platinum or carbon printing. For the former, negatives of a thin or feeble nature are best, and for the latter those of a more vigorous type are desirable. If these latter are used for bromides, there is a general tendency to give hard black-and-white results unless special precautions are taken with the exposure and development. With negatives of the feeble kind there will be a difficulty in getting a brilliant printing negative, though that difficulty may be readily got over by the practised worker.

One of the first essentials, it may be mentioned, in making an enlarged negative for platinum or carbon printing, is a vigorous transparency, and, if the original be feeble and flat, the transparency will partake of a similar character, by whatever process it be made. Therefore, if it be made on a dry plate, the development should be conducted so as to increase the contrasts as much as possible. If the transparency be made by the carbon process—and in some instances this will be the best to employ—it will be well to use a tissue somewhat thin in pigment, such as one of the ordinary portrait tissues, as they give a greater thickness of gelatine in the shadows than the special transparency tissues, and then intensify with permanganate of potash. In developing the enlarged negative, if the transparency still necessitates it, the development should be such as will enhance the contrasts. Now, it will be seen that the negative which is best adapted for one system of enlarging is often just the reverse for another, though, as we have just intimated, both may, with skill, be made available and give good results, although neither is the best adapted for their purpose.

One very desirable characteristic in a negative for enlarging from is that it should be sharp, for it is obvious that, if the original is not sharp, it is impossible to obtain a sharp enlargement from it, whatever may be the system adopted; but with an absolutely sharp negative any desired effect, or degree of unsharpness, may be secured by merely making the enlargement with the lens put more or less out of focus; also with a sharp negative, if it be desired to retain the sharpness at one part and subdue it at another, we can do so simply by using a lens with a somewhat round field—one of the rectilinear type, for example—and working it with its full aperture, focussing upon the portion it is desired to secure with the greatest sharpness.

Here is another point in connexion with negatives for enlarging from that should receive consideration. In hand-camera negatives, on some plates that have been under-exposed and much forced in the development, the image is often very coarse and granular. If such as these be enlarged direct with sharp focussing, the grain with the magnification in the enlargement will be very conspicuous, particularly if the paper upon which it is made is of fine surface and texture. This may, however, be greatly ameliorated by putting the lens very slightly out of focus. This, if judiciously done, will really not materially interfere with the general sharpness of the picture. Granular negatives are, perhaps, best dealt with by the enlarged negative system, because in making the transparency there is, by whatever method, a trifling loss of the finest detail, and so there is in making the enlarged negative from that. These two trifling losses, though not sufficient to mar the general sharpness of the enlarged negatives, render the granularity of the image, if not *nil*, certainly less conspicuous than if it were made, sharply focussed, direct on a smooth bromide paper.

The main object of the present article is to point out that no hard-and-fast line can be laid down as to what type of negative is the best for enlargements without consideration being given as to the method by which they are to be made. One would have surmised, from the title of the lecture above referred to, that these facts would have been pointed out, and thus rendered unnecessary the comments in the report supplied to us of the meeting at which it was read.

---

**Silvering and Gilding Glass.**—The production of a silvered surface upon a glass plate or a telescope mirror is an important operation in some branches of photography, and we have given many recipes at various times for compounding the solutions requisite. The method of pouring the solution upon the glass itself is liable, through inclusion of air bells, to lead to the production of flaws and blemishes in what should be a perfect coating. A foreign journal recommends the following method: The sheet of glass to be silvered is placed in a vessel of glass or porcelain somewhat larger than the glass sheet, the opposite edges of the latter resting upon two cross bars of glass or porcelain. The side of the sheet to be silvered is placed face downwards. Then the silvering solution is poured into the vessel until its surface just reaches the lower surface of the glass sheet, which has previously been cleaned with dilute potash solution and rinsed with distilled water. The silver is soon precipitated upon the glass; the longer the contact, the greater the thickness of coating. The coated article is then removed from the solution and rinsed with distilled water and dried at ordinary temperature. The instructions for gilding are the same, the method of making the solution being as follows, and might be with advantage a little fuller. Three solutions are required—one a solution of chloride of gold; the second, caustic soda in distilled water; the third, the reducing solution of starch sugar dissolved in distilled water with alcohol and aldehyde.

---

**The Nernst Lamp.**—The old and the new forms of the coming lamp, as previously described by us, were shown at the *Conversazione* of the Royal Society. The new form is a neat arrangement, taking 1.5 watts per candle, which increases to 1.67 watts after about 500 hours, when the consumption of current remains about uniform. When run at 2 watts per candle, a life of upwards of 1700 hours has been obtained, and even then the lamp was not worn out. Some idea of the increased light may be formed when it is said that the temperature at which the filament is worked approaches 3600° C., while 2700 is given as about the limit with the ordinary carbon filaments. It is, however, necessary to bring the lamp to a temperature of 636° C. before it conducts. A resistance of platinum wire is used for the purpose, and as soon as it brings the rare earth filament to the requisite temperature an automatic cut-out, applied by means of a short circuiting device worked by a solenoid, at once takes the platinum out of use.

---

**The Cause of the Blue of the Sky and Sunset Colours.**—On the 24th ult. the Right Hon. Lord Rayleigh, F.R.S., gave a discourse upon transparency and opacity at the Royal Institution, which possessed many features of interest to photographers. An abstract is given at some length in last week's *Nature*. It may be said to have been chiefly a consideration of the effects relatively produced when light strikes upon a piece of a transparent body such as glass, and upon the same when reduced to fine or coarse powder. In the latter case it is opaque to light; in the former, as we all know, transparent. If, however, a mixture of benzole and bisulphide of carbon be poured upon the glass powder placed in a flat-sided glass bottle, and the liquid be mixed in such proportion as to have the same refractive index as the glass, the contents of the bottle act as a homogeneous body, and light passes through as though it

were a solid piece of glass. As, however, the two liquids have different dispersive powers, the adjustment of the liquid to glass powder only holds good for one region of the spectrum; for other parts the action is almost the same as the powdered glass itself. Hence, if we look at a small flame backed with a black background, it appears to the eye in its own shape, but strongly coloured. Lord Rayleigh varied the effects in several ways, among them being to use powder from plate glass and liquid cedar-wood oil adjusted with bisulphide of carbon. In this case the free rays, so to speak, extended over a region thirty-four times as large as the separation of the D lines of the spectrum, while with the first-named method (Christiansen's experiment) the region embraced was only equal to 11.3 times. At the close of the lecture the failure of transparency arising from the presence of particles which are small in comparison with light wave-lengths was discussed. The light from an electric lamp was passed through a liquid in which sulphur was slowly being deposited, and the varying amount and kinds of the rays obstructed indicated by the colour of the issuing light the effect of the setting sun. The lecturer also stated his disbelief in the theory that the blue of the sky was owing either wholly or principally to particles of foreign matter. He believed the molecules of air to be capable of dispersing a light not greatly inferior in brightness to that which we receive from the sun.

#### PANAK AND BIRASSOL.

In the *Correspondenz* Dr. E. Valenta reports upon these solutions, which are offered commercially as sensitizers. Panak is brushed upon paper, dried, exposed, and fixed with—

Water.....	100 c. c.
Hypo .....	3 to 5 grammes.
Sulphite of soda .....	1 „ 3 „

The image is dark brown. Analysis shows it to consist of silver, iron, ammonia, nitric acid, organic acids, and sulphuric acid. One hundred parts contain 4.2 parts of silver.

Birassol is a similar preparation, but does not contain any sulphuric acid. There are indications that the brown salt has been used instead of the green ammonio-citrate of iron. Dr. Valenta gives the following formula for the preparation of a similar solution by those interested in the subject:—

#### SOLUTION I.

Green ammonio-citrate of iron.....	2.5 grammes.
Water .....	25 c. c.

#### SOLUTION II.

Nitrate of silver .....	3.5 grammes.
Water .....	15 to 20 c. c.

To Solution II. add ammonia, drop by drop, until the precipitate first formed is redissolved. The excess of ammonia should then be neutralised by carefully adding dilute sulphuric acid until the solution loses all smell of ammonia, whilst yet retaining an alkali reaction. Solutions I. and II. should then be mixed and kept in the dark. The brown ammonio-citrate of iron may be substituted for the green, or ammonio-tartrate of iron may be used, in which case the sulphuric should be replaced by citric acid. The solution then gives brown prints similar to panak. The tartrate gives more vigorous prints, but impairs the keeping quality of the solution. The brightness of the prints is enhanced by addition of gelatine or other suitable viscous substance.

#### PETZVAL'S FIRST PORTRAIT LENS.

Dr. Eder, in the *Photographische Correspondenz*, gives the following particulars concerning this interesting instrument, made in 1841. It has been presented by Ritter von Voigtländer to the Austrian Industrial Museum, Vienna, and photographers will be glad to learn that camera and lens have been preserved intact. The camera is an octagonal cone made of pasteboard with lens fixed at the narrow end, and dark slide with circular opening at the other. A jointed screw is attached to the camera as a means of support. The opening in the dark slide is 97 mm. in diameter. The front combination has a diameter of 39 mm., and the entire lens has an effective aperture of 38 mm. and focus of 15 c. The

following particulars of the elements have been determined by Dr. Rudolf Steinheil. They are given in order, starting with the radius of the front surface of the front lens.

Front Combination	Radius	78.68	Crown (mid. n.=1.528)
	Thickness	7.6	
	Radius	62.45	
	Thickness	1.5	
Back Combination	Radius	653.06	Flint (mid. n.=1.598)
	Separation	51.5	
	Radius	157.96	
	Thickness	1.9	
	Radius	56.01	Flint (mid. n.=1.622)
	Separation	4.2	
	Radius	72.10	
	Thickness	5.3	
	Radius	228.04	Crown (mid. n.=1.546)
	Thickness		

There may be some doubt concerning the refractive indices of the glass, but they appear to be correct, and they show that the front combination consisted of light crown and flint, and the back of heavy crown and flint. Dr. Eder remarks that there can be no doubt that this trial lens had been so carefully calculated that it was found unnecessary to make any subsequent alteration.

#### THE PROJECTED COPYRIGHT BILL.

APPENDED we give such portions of the Copyright Bill now before the House of Lords, together with extracts from the Preliminary Memorandum, as are of interest to the holders of copyright in photographs. The reader is referred to an article on the subject on May 5:—

#### MEMORANDUM.

This Bill is intended to simplify and amend the law relating to copyright in artistic works.

The main features of the Bill are:—

(1.) To secure greater uniformity in the terms and conditions of copyright.

(2.) To reserve to the artist (except as hereinafter mentioned) the copyright until expressly assigned or disposed of by him.

(3.) To make registration of copyright (except as hereinafter mentioned) and of all dealings therewith compulsory.

(4.) To improve the remedies for infringement.

The subjects of copyright are dealt with in three classes:—

(1.) Works of fine art:—(a) Paintings. (b) Drawings. (c) Engravings. (d) Sculpture. (e) Other artistic work (see Definitions, s. 26).

(2.) Photographs.

(3.) Casts from nature.

There are two terms of copyright conferred by the Bill:—

(1.) For an original work of fine art, the life of the author and thirty years after his death.

(2.) For a work of fine art made by one person from the design of another; for a photograph; for a cast from nature; a term lasting until the expiration of thirty years from the first day of the month of registration (see s. 2).

By s. 4 the copyright remains with the author, notwithstanding the sale or disposition by him of the work, until expressly assigned or disposed of by him in writing, or except in case of his bankruptcy (see subsection 2), but (a) where the author is employed for valuable consideration to make a photograph; or (b) to make or assist in making, from the original design of the employer, any work of fine art or cast from nature, the copyright belongs to the employer (see subsection 1), provided that, where the employment is to make any work the subject of copyright, other than a photograph, with the knowledge of the person employed that the work is intended—

(1) for publication (a) as an illustration in a book or newspaper, or (b) as an advertisement, the employer has the sole right of such publication (see subsection 2 (a));

(2) for reproduction as an engraving, or in some other specified form, the employer has the sole right of such reproduction (see subsection 2 (b)).

Subject to the above restrictions, the author's rights remain (see subsection 2 (c)).

Such employer has all the remedies of an author for infringement, and is exempt from registration (see subsection 2 (d)).

With all the above-mentioned safeguards, it is submitted that the reservation of the copyright to the artist should be conceded.

With regard to registration:—

Under s. 16 (1), the author and his executors or administrators need not register so long as the copyright remains in him or them, but, on the copyright passing from him or them, registration is necessary. Under s. 1, however, authors of works first made in the United States of America must register.

Under s. 4 (2) (d), an employer to whom the copyright passes in the

cases provided for in subsection 2 (a) and (b) need not register, and under s. 5 owners of portraits are likewise exempt.

Subject as above, registration is compulsory (*see* s. 16 (1)), and must be effected within six months from the date when the person who is bound to register became entitled, power being given to the Court to extend the time for registration (*see* s. 16 (2)). Failure to register voids the interest which should have been registered (*see* s. 16 (3)). Registration, where compulsory, is a condition precedent to proceedings for infringement (*see* s. 18).

The remedies for infringement and the provisions for repressing the commission of fraud under the existing law are amended and strengthened, and, in addition, is given (a) power to search for and seize unlawful copies in houses and shops; (b) power to seize unlawful copies on hawkers.

These powers were recommended in the Copyright Commission Report of 1878 (*see* paragraphs 173-180).

With reference to Part IV. of the Bill, it should be noticed that by the definition of "copy" (*see* s. 26) every form of copying is intended to be protected, including the reproduction of a picture by sculpture, of a sculpture by any other work of art, and a representation of a picture or sculpture by a living picture (*see* Copyright Commission Report, paragraph 99, and *Hanfstaengl v. Empire Palace* (1894) 3 Ch. 109, and (1895) Appeal Cases 20).

#### A BILL INTITLED AN ACT TO SIMPLIFY AND AMEND THE LAW RELATING TO COPYRIGHT IN ARTISTIC WORKS.

##### Part I.—Nature and Duration of Right.

1. The author, being a British subject, of any work of fine art, photograph, or cast from nature, made after the passing of this Act in any country whatsoever, and the author of any work of fine art, photograph, or cast from nature, made after the passing of this Act in any part of the British islands, or, in the case of any work of fine art, photograph, or cast from nature, first made in the United States of America, registered at Stationers' Hall within three months after its registration in the United States of America, shall have throughout the British dominions copyright as defined in this Act.

2. The copyright conferred by this Act shall, subject to the provisions of this Act, endure for the following terms:—(a) In the case of an original work of fine art, for the life of the author and thirty years after his death; (b) In the case of a work of fine art, made by one person from the design of another, of a cast from nature, and of a photograph, for a term commencing on the completion of such work of fine art, cast from nature, or photograph, and continuing until the expiration of thirty years from the first day of the month in which the same shall have been registered.

4. (1) If any person employs another for valuable consideration to make any photograph, or to make or assist in making from the original design of the employer any work of fine art, or cast from nature, the copyright in such work shall belong to the employer as if he were the author of such work, cast, or photograph.

(2) Except as above provided, the copyright in any work the subject of this Act shall remain in the author, whether such work be sold or disposed of by such author or not, unless the copyright therein be expressly assigned or disposed of in writing by him, or except in the case of his bankruptcy; provided that—(a) Where any person employs another for valuable consideration to make any work the subject of copyright under this Act, other than a photograph, with the knowledge of the person employed that such work is intended by the employer for publication as an illustration in a book or newspaper, or as an advertisement, the employer shall, during the subsistence of copyright in such work, have the sole right of publishing the same as an illustration in a book or newspaper, or as an advertisement, or in any of such forms, but not otherwise. (b) Where any person employs another for valuable consideration to make any work the subject of copyright under this Act, other than a photograph, with the knowledge of the person employed that such work is intended by the employer for reproduction as an engraving, or in some other specified form, the employer shall during the subsistence of copyright in such work have the sole right of reproducing the same as an engraving, or in the specified form, but not otherwise. (c) Neither the author nor his assigns shall publish or reproduce such work in any form of reproduction, the sole right to which has been conferred upon the employer by subsection (a) or (b) hereof. (d) Such employer shall have all the rights and remedies of an owner of copyright under this Act to prevent and obtain damages for infringement of his rights under subsections (a), (b), and (c), and to obtain seizure of copies dealt with in breach thereof, and such employer may maintain an action or other proceeding in respect of his said rights, although neither the copyright in the work in question nor the interest of such employer therein is registered under this Act.

##### Part II.—Infringements and Remedies.

6.—(1.) If any person shall infringe copyright in any work the subject of this Act, by committing any act the exclusive right to do which is, by this Act, reserved to the owner of the copyright in such work, without the consent in writing of such owner or of his agent thereto authorised in

writing, such person shall be liable: (a) to an action for an injunction to restrain such act, and for damages, and for an account of all copies unlawfully dealt with by him; (b) to penalties of an amount to be fixed by the jury hearing the case, or, if there is no jury, by the Judge, not exceeding 20*l.* for each copy unlawfully dealt with, together with twice the price at which such copy shall have been sold or offered for sale, and the costs of the proceedings to be taxed as between solicitor and client; providing that an action for penalties shall not lie against any person who commits, or causes to be committed, any of the acts specified in subsections (b), (c), and (d) of the definition of copyright in this Act contained, and who proves to the satisfaction of the court hearing the case that he had no reasonable ground to suspect that such acts were infringements of any copyright, to the forfeiture and destruction of all unlawful copies, and of any plates, blocks, negatives, moulds, or other similar things, from which such copies were or may be produced, in his possession or control.

(2.) The above remedies shall be cumulative, except that the amount awarded in penalties may be considered in assessing damages, and the amount awarded in damages in assessing penalties.

##### Part III.—Registration.

16.—(1.) So long as the copyright in an original work of fine art remains the property of its author, his executors or administrators, no registration thereof shall be necessary; but, if such copyright or any interest therein shall pass to any person other than the author, his executors or administrators, it shall be compulsory upon such person to register his interest in such copyright. Save as above excepted, registration of copyright in a work the subject of this Act, or of any interest therein, shall be compulsory upon the owner of such copyright or interest.

(2.) Where registration of the copyright in any work or of any interest therein is compulsory under this Act, it shall be effected within six months from the date when the person who is bound to register became entitled to such copyright or interest, or within such further time as the High Court, or a Judge thereof, shall, with or without imposing terms on the applicant, think fit to allow.

(3.) In default of such registration of any copyright under this Act within the time herein provided, such copyright shall become null and void, and, in default of such registration of any partial interest or license relating to such copyright, such interest or license shall determine, but without prejudice in the case of a license to the rights of the author or duly registered owner of such copyright.

17.—(1.) There shall be kept at the Hall of the Stationers' Company, by the officer appointed by the said Company for the purposes of the Copyright Act, 1842, a book entitled *The Register of Owners of Copyright in Works of Art*, wherein shall be entered, except as hereinbefore provided, a memorandum of every copyright to which any person shall be entitled under this Act, and also of every subsequent assignment of or license relating to such copyright.

(2.) Any assignment or license so entered shall be effectual in law without being subject to any stamp or duty, and shall be of the same force and effect as if such assignment had been made by deed.

(3.) Applications for registration, and the entries in the register made thereon, shall be in the forms and contain the particulars set out in the first schedule hereto, with such modifications as the Stationers' Company may from time to time prescribe.

18.—Except in the case of proceedings by the author of an original work of fine art in respect of infringements of his copyright therein, no action shall be sustainable, or any penalty recoverable, in respect of anything done before registration.

Provided that, where any person entitled to copyright under this Act registers such copyright within the period provided by this Act, such registration shall have effect for the purpose of proceedings against infringements as if it had been made on the day on which he became entitled to such copyright.

19.—(1.) The officer appointed by the Stationers' Company shall have power, upon written application being made to him by the registered owner of the copyright in any work the subject of copyright under this Act, and, on his being satisfied of the existence of any inaccuracy in the registration of such work, to make any correction in the name or place of abode or business of the author, publisher, or owner of the copyright of any such work, or in any other matter, as stated in the register, on payment of a fee of 1*s.* for each entry so corrected.

(2.) If the plaintiff in any proceedings for infringement of copyright was registered as owner of such copyright before the infringement complained of, no inaccuracy in the manner or form of such registration or particulars stated therein shall be a defence to any such proceedings, unless the tribunal before which such proceedings are taken is of opinion that such inaccuracy reasonably misled the defendant in such proceedings.

20.—(1.) The Stationers' Company shall in respect of the book of registry kept by them under this Act make and keep an index for each year, showing in alphabetical order the name of every owner or licensee of copyright registered under this Act, with the date of his registration and the reference to the book of registry in which the particulars of registration may be found.

(2.) The said Company shall also, in respect of all works registered under this Act, make and keep an index for each year, showing in alphabetical order the names of the authors thereof, with the title or short description of each work, and the reference to the place in the book of registry where the entry relating to such work may be found.

*Part IV.—Supplementary Provisions and Definitions.*

23.—(1.) The copyright subsisting in any work of fine art, photograph, or cast from nature, by virtue of any enactment in force immediately before the commencement of this Act, shall endure for the term limited by that Act, or for the term fixed by this Act with respect to such works first produced after the commencement of this Act, whichever is the longer.

In this Act, unless the context otherwise requires—

The expression "work of fine art" shall mean a painting, drawing, engraving, or sculpture, or other artistic work.

The expression "engraving" shall mean any work, executed upon any material, whence by any process, whether immediately or mediately, prints may be taken and multiplied indefinitely, other than a photograph, and shall also include any prints so taken.

The expression "photograph" shall include the photographic negative or positive, and any prints or copies made therefrom.

The expression "original work of fine art" shall mean a work of fine art made by a person from, or according to, his own original design.

The expression "copy" shall, subject to the provisions of this Act, mean any representation or reproduction of a work or any part thereof, or the design thereof, in the same or in any other form, and in any material, and in any size, and shall include a reproduction of a picture by a sculpture, or a sculpture by any other work of art, and a representation of a picture or sculpture by a living picture.

**PRACTICAL NOTES ON SOME IRON PRINTING PROCESSES.**

*Part III.—BLUE LINES ON WHITE GROUND.*

*Pellet's Process. Positive Cyanotype.*

The foundations of this process were worked out by Herschel about 1840–2, i.e., about the same time that he introduced the negative cyanotype or ferro-prussiate process (q.v.).

In 1863 Baudesson and Houzeau (of Rheims) employed tartrate or citrate of iron for coating paper, and developed it with ferrocyanide of potassium.

In 1877 Pellet suggested the addition of some such colloid as gum. Gelatine, dextrine, &c., have been tried, but gum arabic seems the general favourite.

*The Paper.*—This should be of a firm, non-absorbent, and well-sized kind. It may be sized with gelatine or arrowroot. For an arrowroot mixture take 5 parts arrowroot and add 100 parts water, and boil slowly until a clear starch-like fluid results.

The following formulae for coating the paper are all highly recommended:—

1. Citric acid .....	40 grains.
Iron perchloride .....	48 "
Gum arabic .....	42 "
Water .....	11 ounces.

2. Oxalic acid .....	5 parts.
Iron perchloride .....	10 "
Gum .....	9 "
Water .....	100 "

A.	
3. Gum arabic .....	8 parts.
Water .....	40 "

B.	
Ammonio-citrate of iron .....	8 parts.
Water .....	16 "

C.	
Ferric chloride .....	5 parts.
Water .....	10 "

Add B to A, with constant stirring; then add C. At first the mixture is rather thick, but, if kept in the dark for a few days, it becomes thin enough for coating purposes.

A.	
4. Gum arabic .....	170 grammes.
Water .....	600 c. c.

B.	
Tartaric acid .....	40 grammes.
Water .....	100 c. c.

Add B to A, slowly stirring all the time. When thoroughly mixed, add 110 c.c. of a solution of iron perchloride, which indicates 45° on Beaumé's

hydrometer. This is practically a fully saturated solution of the iron salt. This mixture is well stirred and kept twenty-four hours in the dark. When required for coating, it is diluted with pure water until it indicates 14° to 15° on Beaumé.

5. Indian ink of a creamy consistency can be added to the coating mixture. The resulting picture is thus made black rather than blue, i.e., a blue-black image is obtained.

Another strongly recommended formula is—

A.	
6. Gum arabic .....	1 ounce.
Water .....	5 ounces.

B.	
Ammonio-citrate of iron .....	1 ounce.
Water .....	2 ounces.

C.	
Iron perchloride .....	1 ounce.
Water .....	2 ounces.

Mix in the following order: Take 10 parts of A; to this add, with constant shaking, 4 parts of B; and, finally, 3 parts of C.

7. The following formula, without any colloid, is also worth a trial, but it must only be used on a very thoroughly sized paper. It possesses the advantage that it is easier to spread and get an even coating.

Oxalic acid .....	5 parts.
Ferric chloride .....	10 "
Water .....	100 "

*The Coating* should be applied with a fairly stiff flat brush, and made even by crossing and recrossing the brush strokes. It should be dried as quickly as possible, i.e., by the heat from a stove, &c., and stored in a dry and dark place. If properly stored, the paper keeps in working order for a very long time. If, after keeping, the paper is found to be working in an unsatisfactory way, it should be immersed in clear cold water for two to three minutes, and then quickly dried. It will now print more slowly.

*Printing.*—This should be in a good light, i.e., strong diffused light, or in the direct rays of the sun if the heat is not excessive. The time for strong direct sun may be about half a minute to a minute. For diffused light the time will probably be four to ten times as long.

*Exposure* is best estimated by employing a small similar negative, under which is placed two or three small strips of paper. These are withdrawn from time to time, and developed on a twenty per cent. solution of potassium ferrocyanide, i.e., yellow prussiate. If, after floating the strip for a minute, you see that the lines are clear and strong blue, and the background yellow, the exposure is sufficient. Over-exposure gives faint lines, patchy and weak. If the ground is stained blue, it indicates under-exposure. The image is visible when sufficiently printed, but only shows very slightly. Test slips should therefore be used until experience is gained.

*Developing and Clearing.*—For these operations three dishes are required. One contains cold water; a second has a solution of potassium ferrocyanide, of strength 20 parts of the salt to 100 parts of water. The exact proportions are not of great importance. The third dish contains either dilute hydrochloric or sulphuric acid of strength 1 to 2 parts strong acid and 100 parts water. To develop a print, first lay it face down on the table, and turn up a strip about half an inch wide all the way round. Now lay it face down floating on the potassium ferrocyanide. In a minute or so examine it. The image should now show a violet-blue on a yellow-green background. If not sufficiently out, it may be returned to the developing bath, or held in the hand a few seconds. When sufficiently developed, immerse in the clean water, keeping it moving for a short time to get rid of the potassium ferrocyanide solution. Next, transfer it to the acid clearing bath, when the print should come a bright Prussian blue colour. It is again well washed and hung up to dry.

*Varnishing.*—It is advisable at times to varnish such prints as maps, plans, diagrams. This may be done as in ferro-prussiate prints, with Canada balsam in turpentine, or thin dammar varnish.

*Corrections* may be made by applying the following solution locally:—

Caustic potash .....	1 part.
Oxalic acid .....	1 "
Water .....	10 parts.

Or a five per cent. solution of potassium oxalate may be used.

Application of the fluid should be made with a quill pen or small brush, and care used to see that it does not run. To prevent spreading action, a little gum arabic may be added.

**SUNDRY NOTES.**

*Ferric Chloride* is the same thing as iron perchloride. It is a deliquescent substance, i.e., attracting moisture, and should, when first bought, be a dry, hard, rather pale yellow colour. On exposure to air, it

crumbles, darkens, and gets sticky. A saturated solution is like treacle, and measures about 45° on Beaumé's hydrometer.

*Potassium Ferrocyanide* is the yellow prussiate of potash of the oil shop.

*Stains on the Fingers* may be removed by a dilute solution of caustic potash, but as this is apt to remove the skin also, care must be used not to employ too strong a solution. As soon as the stain is removed, rinse the fingers well with warm water, and apply a trace of oil for a minute or two, and wash off with soap.

REV. F. C. LAMBERT.

### ART FOR PHOTOGRAPHERS.

At the monthly meeting of the Blairgowrie and District Photographic Association on Tuesday evening an admirable paper on "Art for Photographers," by Mr. A. Geekie (President), was, in his unavoidable absence, read by Mr. J. B. Maclean. The writer stated that the study of the human figure included all the finest principles of the art, and when the eye of the student had been accustomed to see faithfully all the minute circumstances which constitute the character of a figure, and to attend to the innumerable beauties and graceful forms which it presents, he would be better qualified to proceed with advantage to every other branch of the fine arts. In the conception of a picture, he pointed out that there must be a principal object which should receive the principal mass of light, and though a second or third group might be added, and a second or third mass of light, they should all be kept so subordinate that they would not come into competition with the principal. In our endeavours to obtain a pretty picture we forget the different values which were required, and if we knew how to balance one object by another, or understood how each ray of light brought about its corresponding value in shadow, considerable time would be saved and better work done. Simplicity was of the first importance in the design or composition of a picture. The story should be distinctly told, and nothing should be introduced but what was absolutely necessary.

The one great point of simplicity was that it prevented confusion; it gave to each figure or object its position; there was no stepping out of place or jumbling together, as was too often seen in photographs where simplicity had been overlooked. This feature bore directly on photography in various ways: first, in the subject itself; secondly, in the use of backgrounds; thirdly, in the quality of light and shade; and, further still, in the arrangement of light and shadow. The old-fashioned photograph invariably suffered from the hardness of tone as well as exaggeration in the lights and shadows, and generally failed to do more than remotely suggest what it attempted to represent; even now, many of the photographs representing living persons were so stiff and uninteresting as to leave much to be desired. He advised a study of works by famous artists, who, however, should not be servilely followed; the photographer should rather endeavour to imbue himself with their spirit. In conclusion, he said expression was the very soul of art; a picture without expression was nothing.

### FRAMES AND MOUNTS.

THERE was a large attendance at the Croydon Camera Club on Wednesday evening, the 17th inst., to hear "A Chat about Frames and Mounts," by the President, Mr. Hector Maclean.

Mr. Maclean prefaced his lecture by apologising for the "scrappy" nature of his remarks, due to the fact that of late he had had numerous and unexpected calls upon his time; but the ease and comprehension with which he handled his subject made apology quite unnecessary. He began by adverting to the theory that a frame should, to some extent, resemble a hole in the wall or an archway, and pointed out how that the interest and beauty of a landscape are greatly enhanced when framed, as it were, by these means. The frame of a picture should perform a similar office by focussing the eye and concentrating attention upon the print. Frames have been regarded from two points of view, *i.e.*, as decorative objects or as aids to setting off and improving pictures. The first use which might be made of them would not interest his audience, because the more decorative the frame the less effective it would be in improving the picture enclosed. One fundamental maxim regarding frames as aids to pictures is that they should be, almost without exception, inconspicuous and subordinate, and, in the case of photographs the extremes of both high light and darkness in the frame should always be less than in the print. Glitter, vivid patterns, and bright colouring are all harmful, as are strong light or full dark tones. This was illustrated by a reference to the framing of a snow scene, which, being full of half-tone and gradation beautifully rendered, was most unfortunately framed in black and burnished silver, which flattened the whole thing and detracted greatly from its beauty. It was pointed out that, as regards exhibitions, the frame should be calculated to isolate the subject from the other competing prints. In this connexion Mr. Maclean gave his hearers the benefit of his knowledge with regard to the modifications necessary in framing for exhibition as against framing for the drawing-room. He recommended that prints framed for exhibition should be examined first in diffused outdoor light, and explained by analogy of the lantern slide

the differences of effect produced by gallery lighting and ordinary room lighting. As to mounting with a margin or framing close, this really gives rise to no question, as the mount should be considered as part of the frame, and the proper frame is that in which the picture looks best. The best style of frame is often asked for. It is, however, impossible to formulate any universal system, although this would seem to be contradicted by the gift of the Royal Academy. The lecturer pointed out that this was only a choice of evils, and was rendered necessary on account of the clashing which would ensue were framing left to individual taste. Fashion and novelty in framing should not be wholly neglected. Mouldings and materials offer a wide range, and this should be noticed, although, if the prevailing fashion is unsuitable, it is, of course, not permissible. The proportion and shape of a frame are regulated by the picture. Many hold that the only shape for a picture is that of a rectangle in which one side has a ratio to the other of about 3 to 2 or 4 to 3; but it must have been noticed how often a square, circle, or an oval, was the best, if not the only, shape for some compositions. Tone was next dealt with, and the influence which could be exercised by its means would, said the lecturer, sometimes amount to making a success or a failure. The colour of a frame was not less important than its tone. It should never be unpleasant in itself, nor too attractive to the eye, nor raw, primary, or vivid in colour, such as scarlet, cobalt, emerald green, &c., and the nearer its approximation to these the worse is the result. The result of the colour of a frame will be either a harmony, a contrast, or a discord. The latter effect was, of course, only mentioned to be condemned. The modifications to be got by the two former effects in capable hands were lucidly pointed out at some length, and, in conclusion, Mr. Maclean dealt with the subject in a practical way, giving his experience regarding wood and stains.

Mr. Packham, who moved a vote of thanks, and eulogised the able manner in which Mr. Maclean handled his subject, treated his fellow-members to some valuable hints as to the study of colour harmony, and went on to give them the benefit of his experience in wood-working and staining.

Messrs. Slater, Costa, and J. Smith gave recipes for staining; and the City Frame Company contributed several striking prints surrounded in the most approved Salonique solemnity. Upon separating, the members congratulated themselves upon having spent a pleasant and instructive evening.

### FLOWER PHOTOGRAPHY.

At the meeting of the Photographic Club, on May 17, Mr. Thomas Bedding in the chair, the Chairman announced the death of one of the Club's honorary members in the person of Mr. W. B. Bolton, at one time a regular attendant at the meetings of the Club, a body of which he was one of the original founders. Mr. Bolton's life work in the photographic cause was briefly alluded to, and a vote of condolence with his widow in her loss was passed and ordered to be communicated to her.

Mr. H. T. Malby, F.R.P.S., read his Affiliation lecture on "Flower Photography," in which, in a manner calculated to render the best of help to those possessing but the scantiest of knowledge with the special features of this fascinating branch of work, are given the full fruits of the author's thoroughly practical acquaintance therewith. A valuable feature of the paper was the series of slides, many of which compared the possibilities of ordinary and orthochromatic plates with and without colour filters, which, in view of the variety of tints in flower subjects, is a matter of the first importance.

Mr. J. H. Baldock passed to Mr. Malby some of his own work in flower photography, many being taken necessarily in the close confines of a hot-house, where there was little scope for pictorial treatment or arrangement. It was his custom to give a generous exposure, and to develop with a pyro developer, half a grain to the ounce. The lighting was modified by drawing down screens over the housetop, and he particularly wished to know what were the most suitable backgrounds for the work.

Mr. Malby replied that a background of distempred calico had served him very well, and the lighting could be regulated to an extent by means of mats on the roof. The difficulties of working in a hot-house were sometimes exceedingly great, the high temperature and humid atmosphere having before now caused his apparatus to swell and the slides to lock. He preferred pyro for development, but at a vigorous strength, say, two grains per ounce.

Mr. E. Dockree raised the question of size of image in relation to size of original, a question which has been much discussed. Some said that a flower photograph was of no value unless it represented the actual dimensions of the flower, and some of his own work on a reduced scale was the recipient of expressions of opinion to this end. He said there were two sides to the question of flower photography, the purely pictorial and the scientific sides, in pursuing the latter of which he had often given as much as three hours' exposure in order to secure certain essential details of the flower. The matter of background and of suitable colours, therefore, was a difficult one, to which he was still devoting much attention. He referred to the difficulties in the way of photographing certain plants and flowers. The maidenhair fern, for instance, could not be photographed quickly enough to get the detail in the petals, on account

of its continual motion. Certain flowers were still in the shade, but, let a ray of light fall upon them, they immediately become animated.

Mr. Malby replied to these and other points, adding that the colour screens he employed were the original Ilford screens, the pale yellow practically necessitating an exposure of three times the normal, and the dark yellow six times.

Mr. Baldock said he had used a greenish-yellow screen made of chromate of potash, approximating, as Mr. Malby remarked, to the Burchett screens.

#### EXHIBITIONS: TECHNICAL AND OTHERWISE.

[Paper read before the London and Provincial Photographic Association.]

We hear a great deal nowadays about the need for paying more attention in our exhibitions to the technical side of photography. I am going to ask you to-night to bear with me for a little time while we look into this cry, see what it means, inquire whether there is any substantial basis for it, and, if so, how the demand could best be met.

And in the first place, what is meant by the technical side of photography? This seems a simple question to answer, and yet I have heard very few satisfactory explanations of the phrase, as far as an exhibition is concerned. Some people appear to mean examples of good, clean photography, carefully purged from any trace or hint of the pictorial. They profess to desire an exhibition in which an appreciable proportion of the wall space shall be covered by examples of correctly exposed, properly developed, glossily enamelled silver prints, free from all trace of double tones, depicting such things presumably as semi-detached villas, boots of various makes, machinery, interiors of chapels, jars of pickles, groups of footballers, wheelbarrows, prize turnips, and professional beauties. With the single (or married) exception of the last, who are perennially and universally interesting, I ask you how many photographers would go to see such a show? How many members of the great British public would visit it? An exhibition to which no one would go fails to be an exhibition at all. The mere hanging of frames on a wall, and charging for admission to see them, is hardly an exhibition.

The "exhibitees" form an essential feature to my way of thinking. Hence the importance which was rightly attached to the huge total of visitors to the justly celebrated Bradford Exhibition recently. When I went there I found quite fifty people in the gallery, mostly elderly men and children, the former quietly sleeping on the seats thoughtfully provided by the Committee, the latter playing about. I myself, with a morbid desire for singularity, went round and looked at the pictures. Admission was free, so the good people of Bradford poured into their exhibition. It was raining outside at the time.

Visitors, then, are an essential feature of an exhibition, and the kind of technical exhibition I have just referred to would, I am sure you will agree, fall short in this particular. This is one of the ways in which it is supposed an exhibition may "cater for the technical side."

Another explanation of this mysterious want is given. We are told that more attention should be given to the technical side of pictorial photographs. I confess that this might, in a few instances, be done, but surely not in our big exhibitions. To take the case of the Salon and Royal Exhibitions, I cannot recall, amongst the leading pictures in both, going back for several years, any signs that their producers were bad technicians. I ask you, does anybody this side of Hanwell think that, because to get certain effects their pictures have been thrown out of focus, printed through silk or celluloid, allowed to pass although showing signs of movement, Messrs. Craig Annan, Berghelm, Cembrano, Crooke, Davison, Emerson, Hinton, and Sinclair, to name offhand just a few whose work shows some of these peculiarities—I say does any one suggest that any of these workers could not produce what we should here be satisfied to regard as a technically perfect photograph?

I should like to see every picture in every exhibition submitted to a jury of photographers, not focus maniacs, but sensible men—members of the London and Provincial let us say—with instructions to reject every print which bore upon it signs of technical imperfections, and that greatest of all technical defects, *handwork*. Let it be an instruction to them to throw out all double-toned prints, all Chinese-whited prints, all prints trimmed apparently with the teeth, all those spotty and showing signs of halation. None of the recognised leaders of pictorial photography would suffer, except, perhaps, those who disguise good photography with varnish and paint. We should lose no print that we could not well spare, but a few misguided beginners, who have accidentally produced one print, into which those who know far more than they can read intentions and aims that never existed, would receive at the outset of their careers a reminder that they must learn to walk before they run, and we should be spared the spectacle of a high place being given to the accidental result of one who never again made a presentable photograph, and such things have been.

I do not for one moment believe that any photograph would be rejected by such jury which the exhibition would not be stronger without; I do not consider that one really stupid composition, one result of the earnest work of an earnest worker, would be excluded. I do believe that it would mean a very great saving of time and trouble to the jury of

picture-makers who should be asked subsequently to decide which should be hung, or which should be medalled.

In this sense, no doubt, there is room in a good many exhibitions for paying more attention to the technical side of photography.

There is another definition of a technical exhibition, which would refer to one containing specimens of various processes, new and old. As far as these are concerned, there may be room occasionally for some such a show. It entails a great deal of trouble in getting together, and to be of any real use at all an immense amount of labour in cataloguing. Such a show we had last year at the Crystal Palace. It was the most complete of its kind I have ever seen, and probably you will agree with me in this. It was furnished with a catalogue giving the interesting points of each exhibit, the processes were classed together, and, thinking the matter over now in the light of my experience gained on that occasion, I do not know of any great improvements which could be made were another being organized. Small changes for the better in various directions, no doubt, would be beneficial; but I can recall no important example of an instance where it might be made more complete or available.

What was the result of this collection as an exhibition? It was very rarely out of the thousands interested in photography that any one was seen in those sections, and then only because they had lost their way into them, an incident which the general arrangements of the Palace did much to facilitate, and were anxiously trying to get out.

It is, in my mind, a moot point whether from the point of view of an advantage to the public such a show is really worth the trouble and expense it necessarily involves, except perhaps at long intervals.

New processes may be exhibited, and in this direction there is a clear field for the technical side of an exhibition, but this is a very limited one. There are those who complain of the technical side of the Pall Mall Exhibition as inadequate. Its accommodation is poor, no doubt, and I think might be greatly improved with advantage. I do not think, however, that we must look for any very extended exhibition in the shape of results by new processes unless the number of these undergoes a considerable increase. Run your minds back over the last twelve months, and think whether you could cover, say, the walls of this room with specimens by methods new within that time, which should be of interest as such, and not merely as pictures. It can be done when the ground covered is five years or ten years, but one year is too short to give a decided enough advance to make an interesting show annually.

Another direction in which an exhibition may be technical is found in the display of apparatus and material, and herein lies, to my thinking, the one direction in which a good show may be made every year. The present system in vogue at Pall Mall of excluding everything not decidedly novel would not do at all, and it would have to be left to the dealers and manufacturers themselves to decide what they should put in and what they should omit. Every user of a camera, whether a picture-maker, a technical worker, or a plate-spoiler, is interested in cameras, developers, plates, and so on, and would like, I have no doubt, to see under one roof all the varied makes and patterns. Here, then, is room for a truly technical exhibition, and this is the direction in which I think a successful one is most probable.

Having dealt then with what this demand means, the next question to decide is whether there is any basis for it. The real persons to bear the brunt of such a show (I am presuming it is supposed to be an annual one) will be the manufacturers and dealers. If it is to be organized, it is to them that we shall look for the guarantee against financial loss. It may (it probably would) be carried out without any great margin either of profit or loss, but the guarantee would have to come from the trade; they would have to pay the piper, and theirs, then, is the privilege of calling the tune. Have they done so? Has there been, not any determined and organized demand; but, to put it at the lowest, have there been even spasmodic cries for such a show from the trade? I for one have not heard them; have any of you?

No. The outcry has been raised in quite a different quarter. Each year we have two exhibitions—the Salon and the Royal—two essentially picture shows, competing, as we all know them to compete, for the same kind of work—the pictorial. It may suit certain partisans of one or the other to suggest that they are not competitors, that they fill different fields, and that they should continue to do so. But we who see them both know perfectly well that they are keen rivals in the same field; that the highest type of pictorial photograph, the cream of the year's work in artistic photography, the finest show of photographic pictures in fact, is what both aim at. We may hear that the one encourages the fuzzy, the other the sharp, school, but no one really heeds these things.

If we take the finest work of the year, it does not go to one because the other does not appreciate it, but because the other does not get it. I am very far indeed from deprecating this rivalry. As one whose sympathies (prejudices if you will) incline him strongly towards the side of the older exhibition in Pall Mall, I can yet heartily wish well to the Salon. I am sure that the feeling is shared by all who are interested in the R.P.S. We should look upon the failure of the Salon or the breaking up of the Linked Ring as a calamity. There is ample room for both, and they have a stimulating and beneficial effect upon each other. There are, however, one or two turbulent spirits in both camps. In the Salon they cry for

the Royal to pay more attention to the technical side because they fear its competition in the pictorial.

When it suited their purpose they denounced the Society on the ground that it gave no attention to the pictorial side, but was *purely technical*. There has been no marked change in the scope or aims of the Society's exhibition since then, yet now we hear nothing but the opposite complaint. Both cannot have a basis of fact. One or other must be wrong. In my opinion (prejudiced, if you like) both are.

The outcry of the same nature in the Society's ranks proceeds from slightly different causes. Partly, I think, from a fear of competing with the Salon on the present ground, although, the closer the aims of both resemble each other and the keener the competition, the better for both; mainly, I think the idea that the exhibitions should be more technical is based on Lord Crawford's kindly and admirably expressed wish to do something to help the "bread and butter" photographer. In his desire I am sure he will have the sympathy of all of us, the only question is how such help can best be given.

I do not think a class or room reserved for professionals' work would be of much use. I may be wrong, but it seems very questionable what amount of assistance in money or reputation a photographer, say, in Plymouth or Carlisle, is to get from having two or three specimens of his work hung at an exhibition in London.

If we take the very highest class of portraiture, work such as that produced by Messrs. Crooke or Baker, for example, it forces its way by sheer merit into any exhibition already. If the standard is to be lowered—because that is really what it would come to—if the standard is to be lowered until the work of any average professional is admitted, the exhibition would suffer. I have no wish to decry the average professional work; it is what the public demand, and, if better were turned out, they would not appreciate it. The cultivated people, the people who can value at its true worth the work of such men as I have named, is a very small one, and the general run of professional photographers know their business far too well to send out prints which are over the heads of their customers.

The more I think of this side of the question, the more difficult it becomes to see clearly the best way out of it. One would think, from the huge interests now engaged, that photography should be able to maintain an annual exhibition, bearing the same proportion to the photographic trade that the cycle shows do to their own industry. And yet, in view of the fact that the trade do not demand it, there seems little hope of it ever realising.

The most probable, or, at any rate, the most prominent, outcome would be if the Royal Photographic Society were to take such a gallery as the New Gallery—a proposition which I am revealing no secrets when I say is actually under consideration—and organize an Exhibition there on as broad lines as possible. To do this effectively, the lion's share of the space would have to go to the pictorial section. It is the side which interests the largest number of photographers, and which certainly is the most attractive to the general public. The floor area might well be devoted to the trade if the manufacturers and dealers were agreeable. A room—a small one would suffice—could be reserved for specimens of new processes or things of similar interest, and, finally, an exhibition of professional work, if it could be managed, might be included. Whatever happens, the photograph which has no merit beyond that of good technique should be most certainly excluded. The manufacturers have made bad technique inexcusable.

That, gentlemen, is my view of the ideal exhibition of the future, one which is both technical and otherwise.

R. CHILD BATLEY.

### THE WEHNELT INTERRUPTER FOR X-RAY WORK.

SINCE the introduction of the focus tube, we have had no startling advance in X-ray apparatus, or in the methods of procedure. The discovery, by Dr. Wehnelt, of the Electrolytic Interrupter is one of the greatest importance, and it not only marks an epoch in the history of the X rays, but it will in all probability bring about an entire change in the construction of both coils and tubes. For some time investigators have been engaged in the construction of contact-breakers, for producing rapid interruptions, with the intention of getting rid of the obnoxious and irritating flickering of the tubes. The Wehnelt interrupter has done this, and more, for not only are the tubes worked through it as steady as an ordinary incandescent light, but the efficiency of the coil is increased nearly fifty per cent., whilst the condensers and contact-breakers are rendered useless and unnecessary.

The interrupter itself is an exceedingly simple piece of apparatus, and can be made by any one possessed of a small amount of technical skill; but for its use it is necessary that an electric-supply current be available, otherwise it is expensive and difficult to manage, as at least fifty volts are required to work it. The apparatus (fig. 1) consists of a glass jar, beaker, or small accumulator tank (A) containing a solution of dilute sulphuric acid (about ten per cent.); in this are suspended a cathode pole, (B), consisting of a sheet of lead about six inches square, and an anode, which is made by fusing a short length of platinum wire into the end of a curved glass tube (C), which is filled with mercury to make a perfect contact. A piece of the platinum wire, varying from a quarter to an

eighth of an inch in length, projects through the closed end of the glass tube (D), into the acid solution. These electrodes may be suspended through holes in a wooden cover made to fit the jar, or, better still, from wooden strips (E), which rest upon its edges. In another form the lead plate (which may be circular in shape) may rest upon the bottom of the beaker, whilst it is connected with the binding screw on the cover by a narrow strip of the same metal, the platinum-pointed glass tube being suspended above it (fig. 2). This form of apparatus has not in my

FIG. 1.

hands been so successful as the first, on account of the liability of the glass tube to crack owing to the heat generated by the platinum wire when the apparatus is at work. In the first-mentioned form of apparatus the heated water rises to the surface without touching the glass, whilst in the second the glass tube receives the whole of it. The cracking of the tubes may also be avoided by drawing them to a point, instead of fusing the platinum wire into a thick and rounded end.

In regulating the instrument, the distance between the platinum wire and the lead plate is not a matter of so much importance as the size and

FIG. 2.

length of the platinum wire which is allowed to project from the end of the tube. The wire should be about 20 B. W. G., and a quarter of an inch should be allowed to project. If this is found to allow too much current to pass, it can be easily shortened.

In working the interrupter from the 100 or 110 volt current supplied to most large towns, a resistance must be used which is capable of reducing the supply to from eight to ten amperes. This resistance should be adjustable, so that anything between this amount named and the full current can be put on at will.

In connecting up the apparatus with the coil, it must be remembered

that neither the condenser nor contact-breaker is required, so that these must both be cut out of circuit. In most coils this is easily done by connecting with the binding screws which supply the primary coil; in some, however, it is necessary to rearrange the instrument before it can be used with safety. In starting work all the resistance should be used, when, if your platinum wire is not too large, a large violet brush or a rush of sparks should pass between your sparkers, which, by the bye, with a six-inch coil should not be placed more than four inches apart. On lessening the resistance (which must be done very gradually) the stream of sparks will coalesce into one of the ordinary bright colour, and, on still reducing it, this will give way to a continuous flame of a violet-red colour; beyond this point it is dangerous to proceed.

The noise made by this rapid passing of sparks is difficult to describe, as it is almost deafening, and it increases as the resistance is reduced, until with the violet-red flame above mentioned a high-pitched musical note is produced, showing that between 800 and 1500 interruptions are taking place in a second.

In attaching X-ray tubes to the coil thus worked, the greatest possible care must be exercised, as the platinum anti-cathode can be completely melted in under half a minute. Having chosen a good tube and connected it up, it will be noticed that it glows with a steadiness approaching that of an ordinary incandescent lamp, and that with the screen no flickering is to be observed. During working, the tube must be carefully watched, and immediately the anti-cathode becomes red hot the current must be switched off, otherwise it may reach the melting point before steps can be taken to avoid it. The tubes at the present time are not made to withstand the great heat generated by the electrolytic interrupter, and considerable modifications will have to be made in them before they can be used with perfect safety. The platinum will certainly have to be thicker than that generally used, and it will have to be backed with a large piece of metal to help in radiating the heat.

The electrolytic action of the interrupter absorbs a large amount of the electric energy passed through it, so that, by carefully adjusting the distance between the platinum point and the lead plate, and by still more carefully measuring the length and size of the platinum point itself, it is quite possible to work any coil from the electric-light mains without putting any resistance in circuit. As, however, these adjustments can only be made by repeated experiment, and as it is an advantage to be able to increase the amount of current, I should advise a rheostat being used in all cases. There is a great advantage in this, inasmuch as, with a rheostat in circuit, a platinum point can be used which is capable of carrying more current than is actually required; this the rheostat reduces to a workable amount, and if the vacuum of the tube should become higher, and more current be required, the rheostat can be easily adjusted, when otherwise the troublesome process of placing in the interrupter a larger platinum point would be necessary.

With a good large rheostat in circuit there is little danger in working any fairly large-sized and well-made coil with the electrolytic interrupter; without a rheostat, however, advice should be taken before the novice attempts to experiment.

What, it may be asked, are the advantages of the new interrupter? Cumbersome condensers and costly contact-breakers are unnecessary; the efficiency of coils is greatly increased; the flickering of X-ray tubes is overcome, and the time of exposure necessary for producing radiographs is reduced to less than a fifth of that previously resorted to.

A well-built coil, capable under ordinary circumstances of giving a six-inch spark, will, with the electrolytic interrupter properly adjusted, give a continuous stream of sparks nine inches in length, and a coil which was previously perfectly useless for X-ray work will, under the new condition of things, work an X-ray tube to perfection.

I have not experimented with the new interrupter for a sufficient length of time to be in a position to state with certainty exactly what it will or will not do. However, in using it with my nominal 12" spark coils, with which I previously used an improved platinum contact-breaker, I find the difference in the exposures necessary to produce a good negative upon the "Castle" plate (which I always use) to be as follows:—

#### With Contact-breaker. Electrolytic Interrupter.

Hand	... ..	from 40 to 60 secs.	... ..	from 5 to 9 secs.
Arm	... ..	" 60 to 120 "	... ..	" 10 to 20 "
Thigh and knee	... ..	" 3 to 8 mins.	... ..	" 60 to 130 "
Chest	... ..	" 5 to 15 "	... ..	" 1 to 2 mins.
Pelvis	... ..	" 8 to 15 "	... ..	" 1 to 2½ "

These exposures have, of course, been made with tubes specially made for the old methods of working, no others at present being obtainable. It is more than probable, however, that much more suitable tubes will shortly be constructed, when we may look for still greater advances.

The likely alterations which will, in all probability, be made in coils to be worked by the Wehnelt interrupter, it is not my intention to dwell upon. I shall, however, have more to say upon this point later on.

That the Wehnelt interrupter has placed increased power in the hands of all radiographers, there can be no gainsaying. How far this increased power will take us cannot be answered until we have become better acquainted with it.

J. HALL-EDWARDS, L.R.C.P., F.R.P.S.,  
Surgical Radiographer to the General Hospital,  
Birmingham.

May, 1899.

## PHOTOGRAPHY BY PLAN.

THE ordinary photographer looking over his negatives must be struck by their variety of subject: woodland scenes, water bits, country inns, cottages, a church or two possibly, and, if married, his wife and children, collectively and individually. He asks himself, after going through, whether he has had his time and money's worth in pleasure out of them. Yes, he readily admits that he has, but yet thinks he would have had fuller value had there been more negatives of a certain kind. These, in his opinion the best, will turn out to be those taken along the sunny congenial paths of his own particular liking; the ones that express his individuality. There is no necessity for dilating upon the higher pleasure that following one's particular bent gives over a random wandering, nor upon the increased value of result. Added value not merely to the worker himself, but to his fellow-workers and friends generally, for if a man's heart be in what he is doing it shows itself quickly and markedly enough in the quality of the finished product. The evil of it is that individuality is not given fair play. There is not a consistent admission of it as the most important factor in the prospective arranging, nor the actual carrying out, of work. High worth is shown only too often in scraps; a fine bit of material stitched here and there into a patchwork quilt, very different from the artistic and symmetrical design in a carefully woven whole.

Returning to our supposititious critic and his negatives, he may find, for instance, that he thinks most of his landscapes. He should devote himself, at least mainly, to landscapes, but also, and here lies the gist of the contention, form a definite plan to the systematic gaining of a representative series of landscapes. By doing so the pleasures of photography would be immensely heightened to him. The aim might be at gaining his object, say, geographically, county by county; or more broadly by taking natural distinctions of soil, rainfall, and so on, as divisions. Beyond the interest in the individual picture, a far wider one will soon be generated in comparing and contrasting, the flat corn-lands of one district with the undulating pastures of another; the wooded coombes of Devon with bare Yorkshire moors; steep, rugged Welsh mountain-sides with the long easy grades of Cheshire. Water scenes, winding stretches of river, quiet pools, rippled or brawling brooks, may appeal more to another; the ample spaces of the sea, sandy reaches, and contour of coast to a third. But let each picture dovetail in to the forming of a symmetrical whole. Such a whole to a thoughtful mind may gradually and unconsciously lead not only to a truer idea of the topography of one's country, but through it to the logical deduction of the why and wherefore of its past history and present features. The salient actions of old-time warriors and leaders, that led to a fight here, the establishment of a garrison there, the building of an abbey somewhere else, were not hap-hazard ones, but as carefully thought out from a point of favourable position as the more prosaic building of a soap factory, or the laying down of an iron foundry are nowadays. A river had high strategic value, and its spanning by a bridge always made local, oftentimes national, history. One would imagine that, apart from the artistic side, this wider way of looking at bridges would make a photographic collection of them most valuable, suggestive, and interesting. The same applies more markedly still to roads; or the two could be readily combined, their use and purpose lying so closely together. Various types of houses, again, readily lend themselves to similar photographic purpose: stately ducal mansions set in parks, comfortable manors and farm-houses in rich meadow-land, cottages in gardens, rural inns, churches, scraps of village streets, and sleepy county towns. And, to introduce the all-important human element, how much more readily through these can the life and doings of their past and present dwellers and users be built up and truly realised. Where is there a photographic record of British sports? or, if one be more seriously inclined, of British workers and their varied working places? What of different kinds of carts, horses, dogs, boats, and so on in a hundred different directions, in every-day use in different parts of the country? Here is surely ample material for any number of plans, and, instead of being the *dilettante* hobby it only too frequently is, would not photography be immensely lifted in helping to form such items into well-defined wholes?

All very well for a man of leisure and means, but how is it to apply to one short of either, or both? Many may be short of them in the ampler measure necessary for carrying out a very wide plan, but not so, I take it, for a smaller one, or they could not have bought a camera and taken to photography. Let a small plan be made; but, if small, let it be a complete one; the pleasure lies in working to a known finish. The house must be built complete; and although, to carry out the comforting analogy, a large house undoubtedly gains from its size, there is no reason why a smaller one may not be made very proportionate and pleasing, and succeed in filling up the heart of its possessor every bit as fully as the larger one does that of its wealthier owner. It is astonishing, too, how opportunities can be made to gain a much-desired end. Most people, for instance, have no particular reason for taking a summer holiday in a particular place or district; here, as affording the opportunity of adding a brick or two to the structure building, it is supplied them—and a something to boot, to help the passing of the tediousness of leisure unaccustomed to, so often mis-called holiday enjoyment.

Even if a man be really and rigidly bound down to one spot; have no holidays; cannot, strive as he may, give sufficient time to a scheme that

will take him in any way afield—we are not going to give him up. Such fast ties will probably mean that he is married, and, married, fonder of, and more interested in, his wife and children than anything else. Let his scheme be a record of his children from babyhood onwards. With it he may after all be a happier man than his freer brother. The picture of young wife and first baby takes a lot of beating—to the husband and father. A backyard and a suitable camera will be all that are needed for the record, from the catching of characteristic flashes of childish play and earnest, through boyhood, or maidenhood, up to the wedding-group if you like. Like old wine, these negatives, too, get more valuable with keeping; in the quiet of declining life they will have become priceless. When the account of college honour, or, later, of the ampler one of practical life has reached home, what value, pray, would be put by the happy father or mother upon the photographic record of the boy, lovingly looked through and musingly lingered over? And all with the prime essential touch of the personal equation about it; done by one's self. A pity we do not recognise it more fully in pictures of our children. We send them in their stiff, unsuitable best to be posed—fancy posing a child—by a stranger, and bargain for the result at so much a dozen! Small wonder they look such conscious little popinjays set in their plush and bastard art, something and a half-penny, frames! No one can truly photograph a child except his father or mother, and that at home.

But to leave this particular side of our argument; if unduly lengthened out, let love of children bear the brunt of the fault. Enough, I trust, has been said upon the main idea of forming a complete photographic record of an agreeable and interesting something, and being led through it to a general broadening of thought and interest, to induce some adoption of it. The one who does try it will not readily let it drop when the great comfort is experienced of working in the clear light of a definite aim, in place of half-hearted wandering from one thing to another. He will know what to take, and will take it with a set purpose. Better still, he will know what not to take; be one of the few at a picnic or convention outing without a camera, and all the happier for it. JOHN REES.

#### X RAY WORK AND LANDSCAPE ART AT THE CAMERA CLUB.

On Monday, the 14th instant, Dr. Mackenzie Davidson brought before the members of the Club some remarkable advances which he has made in X-ray work for surgical purposes—advances which, it is not too much to say, will mark a new era in the history of operative surgery. At the outset the lecturer explained that his work was chiefly in connexion with hospital practice, and that photography was but the handmaid of his labours; but he proved at an early stage of his remarks that he was a very competent worker with photographic materials.

He divided his discourse, after the manner common in old-fashioned sermons, into three heads; otherwise his lecture was certainly not sermon-like. First he dealt with the Crookes' tube; second, with the localisation of a foreign body in the human organism; and, third, with the production of radiographs for use in the stereoscope.

When he commenced X-ray investigations, he found a great difference in the various Crookes' tubes which he came across, and noticed that some gave remarkably fine definition, whilst others were most deficient in that respect. This led him to carry out a series of experiments in order to find out in what manner this distinct delineation, which is so necessary in surgical work, could be secured, and he was fortunate enough to obtain the services of a good glass worker, in the person of Mr. Cosser, who made various tubes for the carrying out of these experiments. After describing, by means of a diagram, how the cathode rays in a Crookes' tube are brought to a point in front of the anode where the X-rays are generated, the lecturer had a tube made with a movable anode, and finally, by testing this, he was able to fix upon a length between anode and cathode which gave the best possible definition. The methods adopted in the course of this difficult investigation were fully described, the definition being tested on a fluorescent screen by means of a cross-barred frame.

Working the Crookes' tubes at their utmost capacity by giving them all the current that they would bear, he found that the anode became white hot and quickly perished. Finally, he obtained the best results by using an anode of the rare metal, osmium, which he was not able to solder, but held between plates of aluminium. He also tried osmium held between platinum plates, and rivetted thereto to prevent it falling out. Another set of interesting experiments was with a view to control the current from the induction coil by the use of the spark gap, and the ingenious method by which he secured X-ray records of these experiments was much admired. As a result of all his trials, he decided upon one form of tube which gave admirable definition. It was not so lasting as the common form of commercial Crookes' tube, but the perfection of the results it gave more than compensated for its short life.

And now the lecturer came to his second head—Localisation.

When the X-rays were first experimented with, surgeons were so delighted at getting pictures of hidden structures that they did not realise that there was a necessity for localisation if the X-rays were to be of much use to them. For example, suppose that a needle is buried in a person's hand. When the member is submitted to scrutiny by the X-rays, the needle will appear upon the resulting photographic negative

as a perfectly defined white line, much whiter than the bones of the structure, because metal is far more opaque to the Röntgen rays than are the bones. But no one can say from looking at the picture whether that needle is buried in the palm or surface, or in the back of the hand. And in attempting to remove the foreign body the surgeon would, if he judged the needle to be at the back while it was in front, or *vice versa*, subject the patient to much cutting about, which would be, to say the least, extremely unpleasant. The matter would be vastly more serious in the case of a bullet wound in some deeply seated structure of the body.

By the apparatus which Dr. Davidson has contrived the operator is able to exactly localise the precise position of any foreign body in the flesh of which the X-rays can form an image. In the first place the Crookes' tube is so fixed upon a stand above the operating table that it can be moved laterally a distance of, say, three inches. A radiograph of the subject is taken first with the tube in one position, and then another is taken with the tube moved to its other place, three inches away. The result is two images of the bullet, or whatever may be the nature of the foreign body, on the plate, together with the images of two wires at right angles to one another, which are used as guides. Knowing the exact distance of the tube from the photographic plate, and with the help of these images, it becomes a simple matter to calculate the exact position above that plate of the foreign body which the surgeon wishes to remove.

But the most remarkable part of Dr. Davidson's achievement remains to be described. He has more particularly directed his attention to the detection of foreign bodies in the eye. Such accidents are far more common than most persons would suppose, and at our hospitals workmen are constantly presenting themselves with a chip of metal which, glancing from the lathe or chisel, has struck and buried itself in the eye. A foreign body will often remain in a limb throughout life, and will give no trouble at all, but with the eye it is very different—it must be removed, or the eye must be removed; if allowed to remain, the other eye will probably be affected by sympathy with the injured organ, and blindness of both eyes results. Hence the great importance of a method of detecting the exact position of one of these dangerous fragments, which may be almost too small for the unaided vision to appreciate. That the method which Dr. Davidson has invented and adopted is effective is evident from the fact that up to the present time it has been used effectually in no fewer than a hundred cases in the various London hospitals.

The patient sits while under examination by this method, and his head is, so to speak, wedged into one position, so that it remains perfectly rigid. Behind him, against the eye to be examined, is the photographic plate, held vertically in a frame, and in front the Crookes' tube upon its movable stand. A tiny metal wire, secured on the eyelid by a piece of adhesive plaster, gives the necessary base line from which the exact position of any foreign body in the eyeball can be subsequently calculated.

Instead of taking the two images of a foreign body on one plate, the lecturer prefers to use a separate plate for each, and this plan has the advantage that the two pictures can afterwards be employed for use in the stereoscope. Various paired pictures of this kind were dispersed about the Club room, and members had an opportunity of closely examining them. The form of spectroscope employed was the primitive form of Wheatstone's, with the angled mirror. The lecturer concluded his remarks by a description of the new electrolytic break for the induction coil, which is so effective for X-ray work, but which, alas! is rather destructive to the tubes employed.

Dr. Mackenzie-Davidson's paper was much appreciated, and was followed by a brief discussion, in which Mr. Inwards (the Chairman), Professor McHardy, and others took part.

On the following Thursday—the last night of the present session—Mr. Alfred East, Associate of the Royal Academy, gave one of his charming discourses upon art—that is, the art of the landscape painter. The ordinary camera man is apt to fight shy of these discussions upon the art side of photography, but Mr. Alfred East found a large audience awaiting him, and a brother of the brush in the person of Mr. Storey to act the part of chairman in his usual genial manner.

First, then, came a word of good-humoured introduction of the lecturer from Mr. Storey, who told the audience that his own place in the assembly was merely to keep order and prevent any fighting. They all regarded Mr. East in the light of an ally rather than as an opponent, and he felt sure that they would learn that evening much that would be of use to them as photographers.

Mr. East said that there were many technical difficulties in the art of painting which did not assail that of the photographer, but they all met upon one common ground in their love of art. Nature was not perfect by any means, and it was the art of the painter to select from the wealth of subject offered to him that which would suit his purpose or the purpose of his picture. This was comparatively easy for the painter, but a difficult matter for the photographer. Still, the photographer can often exercise a considerable amount of choice in this matter of selection. Thus he can decide in his picture upon the proportion of earth to sky, and earth to foliage. He should approach Nature in a spirit of receptivity, and should endeavour to get all from Nature which appealed to him as an individual, so that people should afterwards recognise in his work something distinctive in his methods.

With regard to the all-important matter of selection, we should first of all consider the worthiness of the subject which we propose to transfer to canvas or plate—does it contain those elements which will illustrate our emotions? There is a great deal of personality in the matter, and each artist will select that which appeals to him most.

Next there is the important question of the amount of lights and darks in a picture, and the contours of those lights and darks. If these contours are agreeable, that is a long step towards a satisfactory picture.

Mr. East next dealt with the different methods adopted by well-known painters, and especially dealt with the colour schemes of Turner, and pointed out that it was the practice of that great painter to have a counter-point to each colour employed. It might be a figure, perhaps ill-drawn, but giving the point of colour required at the right place. Of course, a photographer could not deal with colour, but it was in his power to obtain contrast by the introduction of figures in an intelligent manner.

A few useful notes followed upon the cutting down of pictures; it was shown how sometimes a composition will gain in apparent size by being in reality reduced. Thus, in the case of a mountain scene with a redundant sky, the mountain will appear much higher if a strip of sky be sacrificed to the pruning knife.

Contrasts of colour for the painter were compared with contrasts of form for the photographer. We are all the victims of inherited convention, and this governs our handwork to a remarkable degree. We frankly accept certain conventions of form and construction as being correct, and this was strongly apparent in the landscape work of artists previous to the time of Constable. It was universal then for foliage, for example, to be painted in a set conventional manner which to-day is horrible to contemplate. Constable changed all this, representing things as he saw and felt them, and painters who followed him happily did the same. Photographers would do well to emulate the same spirit of independence. In this way they would get many followers, and perhaps touch many hearts.

Lastly, Mr. East said a few words about artistic photography, and, in approaching this part of his subject, expressed the hope that he would not tread upon any one's toes. He had a respect for sharply focussed work for certain subjects, and, going to the other extreme, he pointed out how dangerous was the "fudging," or faking, of a negative, so as to obtain a universal blur upon the resulting picture. A tree had a trunk, which was hard in outline, while it had softly defined foliage; by blurring all its parts, its character is obviously destroyed. Some things we might blur, and give the idea of life, and he had seen some marvellous photographic results obtained in this way, but he must confess that they were not always satisfactory. Whatever is done must be done with a view to preserve the character of the thing dealt with.

In many moving subjects, such as the flight of a bird and the gallop of a horse, the points of "extension and recover" were the only paintable incidents. A photograph would show the intermediate attitudes, and such pictures were most useful as studies. He would recommend photographers to study Turner's *Liber Studiorum*, as well as Claude's *Liber Veritatis*, for both books gave valuable lessons in composition. Let them try to invest all their work with the idea of life and movement, which were the predominant and most beautiful characteristics of good art.

The discussion which followed Mr. East's paper was not a very satisfactory one. He happened to give passing notice, by way of illustration, to a certain picture with a moon in it, and, by some strange conceit, the discussion ignored all the best features of the paper, which really bristled with controversial matter, and seized upon this wretched moon as a peg upon which to hang endless harangues. Member after member arose to talk about the apparent size of the moon when at the zenith or on the horizon, until a stranger might have thought that he was in a lunatic asylum rather than a healthy club. When, at length, the talkers had done with the moon, the discussion came to an end, and all joined in a hearty vote of thanks to the accomplished lecturer.

## Our Editorial Table.

### STARS AND TELESCOPES. A HANDY BOOK OF ASTRONOMY.

Founded on the Ninth Edition of Lynne's *Celestial Motions*. By DAVID P. TODD, M.A., Ph.D., Professor of Astronomy and Director of the Observatory, Amherst College, author of *A New Astronomy*, &c. With maps and 219 illustrations. 12mo. Cloth, gilt top, 2 dols.

Little, Brown, & Co., 254, Washington-street, Boston.

PROFESSOR TODD's new work, *Stars and Telescopes*, is practically a compendium of astronomy in all its branches. It gives full and accurate information on all important phenomena of the heavens, and makes use in this of the latest discoveries. There are chapters on "The Calendar," "The Astronomical Relations of Light," and "Solar Physics;" also one on "The Cosmogony," giving Professor See's new theory of cosmic evolution. Besides these and other more familiar discussions, the book contains the story of the great telescopes, and the progress effected by them, together with sketches of noted astronomers; and the reader who

desires to go to original sources will find these indicated in bibliographic lists, which follow each chapter. The illustrations are very numerous, and, being as varied as the text, have great interest. In view of the wide field covered, this book will prove, it is believed, a model of completeness and scholarly statement. The enormous part which photography has played in astronomical progress during recent years is fully set forth, and the book, as a source of reference, is simply invaluable. In minuteness of detail it is remarkably complete, and we have not for a long time had through our hands such a painstaking production.

### THE YEAR BOOK OF PHOTOGRAPHY AND AMATEUR'S GUIDE FOR 1899.

Edited by E. J. WALL, F.R.P.S. 660 pp. Price 1s.

London: Published at 9, Cecil-court, W.C.

THE annual of our contemporary, the *Photographic News*, appears at a time of year when an amateur's interest in photography is thoroughly reawakened. Mr. Wall has so cast his volume that it appeals to a very large class indeed. His own introductory article is on the subject of "Practical Instructions for Enlarging," in which a great deal of useful information is given in terse and direct language. Following this article there is a lengthy review of enlarging apparatus, and papers and formulae, so that all possible information is crystallised round the main subject. Other articles are: "Architectural Photography," by C. H. Oakden, a tried expert in this branch; and "Shutters," by E. H. Birney. About 100 pages are devoted to the Photographer's Gazetteer, a very useful feature indeed for the tourist photographer. Mr. Hepworth gives an article on "Practical Hints for Lanternists," and there are many formulae, illustrations and reviews of apparatus, so making the *Year Book* a thoroughly serviceable amateur's guide.

### THE PLATINOTYPE PROCESS.

By W. J. WARREN.

London: Iliffe, Sons, & Sturmer, 3, St. Bride-street. 89 pp. Price 1s.

MR. WARREN's addition to the literature of platinotype printing is a simply worded exposition of the principles and practice of this most popular process. It is just the kind of book to place in the hands of the beginner, in the reasonable certainty that such a one will find no difficulty in understanding it. The author is on safer ground here than when dealing with a less exact method of "printing," such as gum-bichromate, which has been killed by ridicule, and the details, practical hints, and personal experiences that he gives are sure to be appreciated, coming as they do from a very able photographer indeed. The frontispieces show imitation specimen platinotypes before and after development.

### CATALOGUE RECEIVED.

Edinburgh: A. H. Baird, 37, Lothian-street.

MR. BAIRD's catalogue aims at including "everything photographic," and a glance through its ninety odd well-illustrated pages shows that mention has been given to most of the requirements of the modern photographer. The catalogue is well produced, and is handy for reference.

WE have also received the *Tourist's Vade-mecum of Spanish Colloquial Conversation*, published by Sir Isaac Pitman & Sons, Limited, of No. 1, Amen-corner, E.C. Two or three pages are devoted to photographic questions, and the pronunciation of the Spanish equivalent is given in each case.

## News and Notes.

MR. JOHN A. HICKS, trade enlarger, has removed from No. 291 to No. 355, New Cross-road, London, S.E.

PHOTOGRAPHIC CLUB.—May 31, at eight o'clock. "Demonstration of X-Rays with Fluorescent Screens up to Date," by Mr. J. R. Gutz.

MR. D. L. EVANS, dispensing chemist, 27, Walter-road, Swansea, has had built a very commodious dark room for the free use of amateurs and tourists.

MESSRS. DAVID BURNETT & Co. sold at the Mart last week the freehold of No. 54, Cheapside, in the occupation of the London Stereoscopic Company, for 28,500l. This price is equivalent to 60l. per foot super. in possession.

THE BAY STATE PHOTO CO., of 124, Hospital-street, Nantwich, write: In answer to your correspondent, A. W. Andree, for the address of S. Wing, the patentee of ferrotype apparatus, I enclose it: S. Wing & Co., 100, Cambridge-street, Charlestown, Boston, Mass., U.S.A.

AN interesting work is promised in a few days by Messrs. Horace Marshall. It is entitled *Mr. Pickwick's Kent: A Photographic Record of the Tour of the Corresponding Society of the Pickwick Club in Rochester, Chatham, Dingley Dell, Muggleton, Cobham, and Gravesend*. The author, Mr. Hammond Hall, gives some hitherto unpublished Pickwickiana, and the work is illustrated chiefly by photographs specially taken by Mr. Lionel Gowing.

**BRITISH EXHIBITS AT THE PARIS EXHIBITION.**—The Royal Commission for the Paris Exhibition have issued their first list of exhibitors to whom space has been allotted in the British Section. In the groups of manufactures and various industries the British firms number 500, and are thoroughly representative. It is made compulsory for exhibitors to place prices on their goods in French equivalents. The competition for space has been so keen that the various committees of the Royal Commission experienced great difficulty in making their selections, and, owing to the limited space, out of some 2000 applications more than half had to be refused.

**THE STORAGE OF CARBIDE OF CALCIUM.**—At the Reigate County Bench, on Saturday, Mr. F. C. Morrison, on behalf of the Reigate Rural District Council, made application for a warrant empowering Mr. Talbot Kyle, the County Inspector, to search the premises of Mr. Wells, Green Farm, Smallfields, Burrow, under the Petroleum Acts. Mr. Kyle, he said, had every reason to believe that Mr. Wells had larger quantities of carbide of calcium stored on his premises than were authorised under the Act. In reply to Mr. Kyle, Mr. Wells had written saying that he had a stock of calcium of carbide for his own use. The legal quantity allowed to be stored was five pounds. Mr. Kyle, on being sworn, said he had reasonable grounds for believing that a larger quantity than was allowed was being stored by Mr. Wells. The application was granted.

**WHAT'S IN A NAME?**—At Colchester Bankruptcy Court last week, before the Deputy Registrar (Mr. Joseph Lee), Thomas York Morter, photographer, &c., carrying on business as "T. & E. Morter," in Queen-street, Colchester, attended for his adjourned public examination. In reply to the Official receiver (Mr. Messent), the debtor said he traded as "T. & E. Morter" with the object of turning the business over to his two sons, Thomas and Ernest. His wife's initial was "E." but she had never taken any part in the business, and was not indicated by the "E." He commenced business as "Thos. Morter," but Mr. Kavanagh, in whose employ he was at that time, objected, and he then altered it to "T. & E." Mr. Sichel, a creditor, also examined the debtor upon the same point, and observed that the debtor was now applying for fresh credit as "E. Morter." The bankrupt said it was his wife who wished to start business now, and Mr. Asher Prior, appearing for the debtor, intimated that it was merely an application for goods on the hire-purchase system. The examination was closed.

In a communication to the *Lancet*, Drs. S. Stephenson and D. Walsh say: "From time to time sensational reports have been published as to the effects of the Röntgen rays upon various defective conditions of the eye. It was asserted, for instance, that cases of blindness had been relieved by the aid of the focus tube. In the hands of competent observers, however, the results of similar experiments have proved negative. The fallacy of the original observations may have lain in the fact that they dealt with cases of hysterical blindness—that is to say, with patients who might profess themselves cured under any novel plan of treatment. Or, again, the blindness may have been due to opacity of the cornea, or of the lens, whereby ordinary light would be excluded, but no resistance would be offered by the opaque tissues to the passage of the Röntgen rays. A reference to some of the early literature on the subject shows that none of the alleged cases stand the test of critical examination. It has lately been claimed that the retine of colour-blind persons were acted upon strongly by the Röntgen rays. In order to test this assertion, four colour-blind children were subjected to the rays emitted from an ordinary bicond focal tube attached to a twelve-inch coil working at nine inches. The children were two of them aged eight years, one nine years, and the fourth eleven years, and of good intelligence. Their colour sense was defective in red-green, and their form sense was normal. Perception of light and form proved normal when tested by the screen enclosed in a bellows fluoroscope. When the children looked steadily at the brilliantly lighted tube, they showed no signs of photophobia. They all recognised objects, such as keys, when held against the bare tube or against the screen. The after-phosphorescence of the tube was seen by all of them, as well as the greater intensity of the area in front of the anti-cathodal plane. Lastly, there was no sensation of light when the eyes were shut and bandaged, and the children put in front of the 'live' tube at the level of the eyes. To sum up, there was no reason to suppose that the retine of these four colour-blind children reacted to the focus tube in any way differently from those of folk with normal colour sense."

## Patent News.

The following applications for Patents were made between May 8 and May 13, 1899:—

**ANIMATED PHOTOGRAPHY.**—No. 9783. "Apparatus for Taking and Displaying Photographs of Moving Objects." M. BARR.

**CAMERAS.**—No. 9874. "Improvements in Photographic Cameras of the Reflex Type." A. J. E. HILL and PHOTO, LIMITED.

**SHUTTERS.**—No. 9884. "Improvements in or relating to Focal Plane and other Roller-blind Shutters for Photographic Purposes." A. L. ADAMS.

**CAMERAS.**—No. 9895. "Improvements in or relating to Photographic Cameras." T. K. BARNARD and F. GOWENLOCK.

**DISHES.**—No. 9920. "An Improved Dish for Washing Photographic Prints." R. ST. C. HOUGH.

**ANIMATED PHOTOGRAPHY.**—No. 9954. "Improved Apparatus for Displaying Animated or Zoetrope Pictures." E. CADETT, A. G. MACCULLOCH, and H. DICKINSON.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
29.....	Bradford Photo. Society .....	Miscellaneous Evening.
30.....	Birmingham Photo. Society ..	Members' Lantern Evening: Series of slides illustrating Gwydyr Castle. R. Haines.
30.....	Hackney.....	Suitable Printing Processes. J. A. Sinclair.
30.....	Lale of Thanet .....	Annual Excursion.
31.....	Photographic Club .....	Demonstration: X Rays with Fluorescent Screens—up to Date. J. R. Gotz.
June.		Discussion on Subjects of Photographic Interest. Exhibition of Pictures taken on Easter Excursion to the Wyke Valley.
1.....	Liverpool Amateur.....	A Chat on Stereoscopic Photography. J. E. Hodd.
1.....	London and Provincial .....	Excursion: Knott Hill and District. Leader, W. C. Brown.
3.....	Ashton-under-Lyne.....	Excursion: Waltham Cross and Abbey. Leader, S. H. Kemble.

3.....	Hackney .....	Excursion: Turton Tower. Leader, T. Burton.
3.....	Oldham .....	

### ROYAL PHOTOGRAPHIC SOCIETY.

MAY 23,—Technical Meeting.—Mr. J. J. Vezey in the chair.

#### KOREA.

A large audience, which included a considerable number of ladies, assembled to hear a lecture by Mrs. ISABELLA BISHOP, the well-known traveller and explorer, on "Korea," a country which has lately been much talked about, but of which very little is generally known. Korea is about the same size as Great Britain, with a population of about seventeen millions, a country of mountains and valleys, with no plains, a splendid climate, and a sufficient rainfall, but it has practically put up the notice, "Travellers will have their throats cut," an unpleasant possibility which did not deter Mrs. Bishop from paying four visits between 1894 and 1898, spending six months on two journeys in the far interior, and six months on two visits to Seoul, the capital. Its history began in 1122 B.C., when it was conquered by a rebellious Chinese general, who imposed upon it an alien civilisation, which has lasted unimpaired to this day, laws, religion, and social and political order remaining quite Chinese. Up to 1876 the seclusion of the country was maintained, the only people who had succeeded in getting into it being some Jesuit missionaries, who must have been very successful in making converts, for in 1896 the present King's father destroyed, at a place three miles from the capital, nineteen bishops and priests, and 2000 Korean converts. In 1876 a commercial treaty was entered into between Korea and Japan, but the Japanese were confined to a few miles of country round the port of Fu-san, and failed to trade there, or anywhere else, and in 1884 other treaties were formed, including one with England. Seoul (the capital) is twenty-five miles inland, and, as there are no roads in Korea and no wheeled vehicles, travelling is very difficult. The city is magnificently situated upon a hill, and is surrounded by a wall fourteen miles round and forty feet high, running up and down hills, descending into valleys, crenulated, and with eight very fine gate towers. It is a city of wig-wams, a dead level of thatched roofs, sheltering over 250,000 people. Throughout the day the streets are crowded with men, women being abroad, but at eight o'clock each evening a great bell sounded, and then until midnight the women folk may come out, no man being allowed out of doors within those hours, except blind men and those having business at the druggists' shops. Mrs. Bishop dryly remarks that blindness was apparently very prevalent and that a great many prescriptions had to be made up. This ordinance, however, is very strictly enforced on the women, for many of them told Mrs. Bishop that they had never seen the outside of their own houses by daylight, and the Queen said that, although she had twice accompanied the King on Royal processions, she had never seen more than two streets of the capital. The King was described as a man of a thoroughly bad type, with no sense of justice, no truthfulness, no honour, no patriotism, his own idea being to squeeze all he could out of the people for his own pleasures and gratifications. He changes his ministers with alarming frequency, and a change of ministry always means the fall of several heads, and the consequence is that the country is wretchedly and miserably governed. The one ambition of every Korean is to possess a brass dinner service, but such a luxury inevitably brings about visit from the mandarin, who confiscates the family plate, and makes increased exactions on the ground of the wealth of its unhappy possessor. Although Mrs. Bishop had little that was complimentary to say for the King or the upper classes, and nothing but pity for the oppressed peasant, she highly eulogised the country itself, which is extremely picturesque and very fertile, being capable of supporting a much larger population than it possesses. Her lecture throughout was of the greatest interest and was illustrated by a comprehensive and unique series of lantern slides from her own negatives. It was not an explorer's lecture, but rather full and graphic account of the life, dress, manners, and general characteristics of the Koreans, and was listened to with evident pleasure by the large audience, applause being frequent and hearty.

#### COMING EVENTS.

The CHAIRMAN said that, in consequence of the *Conversations of the Society of Arts* having been arranged for June 20, the proposed reception at Society's new house in Russell-square would not take place on that day.

was proposed, however, to hold that function on June 27, but no final arrangement had yet been made. At the Ordinary Meeting, on June 13, Professor Vivian Lewes will read a paper on "Acetylene," and on June 20 Mr. Redmond Barrett will probably discourse on "Retouching."

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 18.—Mr. Robert Beckett in the chair.

Mr. R. CHILD BAYLEY read a paper entitled

##### EXHIBITIONS, TECHNICAL AND OTHERWISE. [See p. 329.]

Mr. J. E. HODD thought the lecturer had struck the right note in suggesting that the trade could help very much towards making exhibitions more popular and more profitable from a promoter's point of view. He felt that the trade would be glad of an opportunity of stepping in to help create a new interest in exhibitions, and there were many points in favour of the New Gallery to recommend it for an exhibition. To indicate the interest the trade had already shown in such exhibitions, besides the Crystal Palace Show, there was that at the Portman Rooms, which was well patronised and proved helpful to everybody; and Eastman's Exhibition at the New Gallery was perhaps the biggest success in the direction of combined pictorial and trade exhibitions, though confined to the wares of one firm, that had ever been held. He thought that, in these days of perfect materials and appliances, mere good technique was little to base claims for distinction upon. There was no excuse for bad technique nowadays whatsoever.

Mr. A. T. HARRIS thought that, so long as promoters of exhibitions set themselves the task of finding methods of making the trade bear the expense, so long would the trade be unlikely to take up with exhibitions to a large extent. It was only reasonable that, if the trade were expected to pay the costs, they should receive more space and more encouragement. The trade was not philanthropic, but a money-making concern, and it was a poor inducement, after incurring much expense over a stall, to be visited only by a class of people who looked at the apparatus and materials from everything but a purchaser's point of view. He was convinced that the photographic trade was an energetic one, and one which, given the chance, would be quite ready and willing to come up to the front.

Mr. A. MACKIE thought that the doctrine that anybody could edit a paper better than the editor himself was applicable to photographic exhibitions, for it seemed that the biggest fools in the world were always chosen to manage exhibitions, according to many. As a matter of fact, any exhibition must necessarily be a series of compromises, and there was no such thing as a perfect exhibition. It was not to be supposed that, when an individual finds something obviously wrong at an exhibition, it is due necessarily to carelessness. Often enough that very point which looks wrong has been the subject of much consultation, and is only as it is seen because its alteration would involve defects worse than itself. He agreed with the lecturer, regarding technical exhibits, that a display of purely technical work would have no attractions for the average member of the public. He had not the slightest doubt that the majority of people who went to exhibitions went to see what was termed pictorial work, and only a very small section of the public was at all concerned with photography in its technical aspects. How many people in a thousand, he asked, were interested in the most remarkable of photographs of the heavenly bodies, or any other of the various applications of photography? He thought very few indeed.

Mr. W. D. WELFORD said that, seeing that photographic exhibitions were supported entirely by the public, it was due to the public and to their money that the exhibition succeeded. The promoters had to look to the public for the money to support the exhibition and make it pay, and it was nonsense to talk about catering for any one class. In an exhibition there were bound to be a number of conflicting elements which it was a difficult matter to combine.

Mr. S. HERBERT FRY said it occurred to him that these exhibitions were not held from any one single motive. The main consideration in his mind wanting elucidation was why photographic exhibitions were held at all. The main object of the Pall Mall Exhibition, he took it, had been the advancement of photography, and the officers and many members, in the most unblushing way, say they do not mind whether it pay or not. In fact, they are rather proud now that it does not pay. But, while this may be a legitimate reason for the Royal, whether any other body would think so is rather unlikely. Another reason for exhibitions lies in the fact that many societies keep together alone by their help, and an entirely different set of rules would obtain for this purpose than for the other. Then, the Salon, originally started from party motives, it is maintained because excellent work is shown there. However, to his mind, the notion that professionals were at all interested in exhibitions was a fallacy.

The CHAIRMAN expressed the opinion that Judges should give reasons for their decisions, and that in this way an incalculable amount of help was to be given.

There was a long and interesting discussion upon the paper and exhibition matters as a whole, to which Mr. Bayley finally responded.

North Middlesex Photographic Society.—May 15, Mr. S. E. Wall in the chair.—Mr. H. W. BENNETT, F.R.P.S., gave a lecture on

##### PRINTING FROM THE NEGATIVE.

He described the principles of the various printing processes and the class of negative suitable to them. Carbon required the densest, then platinum, albumen, and gelatino-chloride in the order named. In the rendering of detail gelatino-chloride came first, then carbon, albumen, and platinotype the last. He set forth the advantage of using an actinometer for platinotype, and passed round one contrived by himself, the principle of which was judging by the faintest square shown on printing through layers of tissue papers in graduated numbers. He used in this P.O.P., finding that, even on keeping a considerable time, the speed of printing did not vary appreciably. He also gave relative speeds of the various commercial sensitised carbon tissues, judg-

ing from a P.O.P. print printed as appeared right before toning and fixing. Brown tissue required longer printing than black. He also stated that the home-sensitised tissue was considerably faster than ready-sensitised, which was endorsed by several members.

Hove Camera Club.—At the General Meeting the following were elected officers for the year 1899-1900:—President: Mr. G. B. Woodruff, Mayor of Hove.—Vice-Presidents: Messrs. Charles Job, E. E. Manwaring, and W. H. Hornsmon.—Committee: Messrs. W. A. Frid, F. C. Foskett; D. J. Gadsby, H. S. Gilkes, R. C. Ryan, and A. R. Sargeant.—Hon. Treasurer and Secretary: Mr. C. Berrington-Stoner, 24, Holland-road, Hove.

Leeds Photographic Society.—The winter session of the above Society was brought to a close by a *Conversazione* held in the Philosophical Hall, Park-row, Leeds, on Tuesday, May 16, when the President of the Society (Mr. Godfrey Bingley) and Mrs. Bingley received the members and their friends. The early part of the evening was devoted to witnessing practical experiments of a nature especially interesting to the amateur photographer. Mr. F. W. Branson, F.I.C., gave an exhibition of the new apparatus for the creation of the now well-known and serviceable Röntgen rays, and demonstrated the production of cathode and Röntgen rays direct from an alternating current of fifty volts by means of Wehnelt's electrolyte "make and break" and an induction coil without condensers. This, being a comparatively recent discovery, proved a great attraction, as no public experiment of the kind had previously been made in the city. Wireless telegraphy was demonstrated in the lecture theatre by Mr. WILLIAM WALLACE, M.A., F.R.S.E., who showed in operation a series of exhibits to illustrate the subject, and gave a short and instructive explanation of the different methods employed by Preece, Lodge, and Marconi. The President also exhibited a series of lantern slides illustrative of a tour in East Anglia. The second portion of the programme was taken up by a concert in the lecture theatre, songs (humorous and otherwise), recitations, and pianoforte solos being ably rendered. A short statement was made during the course of the evening by the officials, showing that the Society was in a most flourishing condition, and announcing a very attractive syllabus for next session. The whole proceedings distinctly pointed to the great interest taken in the Society's welfare by photographers in the city, and augured well for the membership roll in the forthcoming season. A vote of condolence was passed with the family of the late Dr. Bendelack Hewatson, who was a prominent supporter of the Society.

## Correspondence.

- \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

#### BAS-RELIEF PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—With reference to the correspondence relating to the secret process for the production of bas-relief photography, and your editorial comments thereon in THE BRITISH JOURNAL OF PHOTOGRAPHY of April 28 and May 6, we beg to state that our solicitors have instructions to prosecute any person found infringing our patent rights.—I am, yours, &c., for and on behalf of the Taber Bas-relief Photographic Company, J. H.  
141, New Bond-street, W., May 18, 1899.

#### A SOCIETY FOR PHOTOGRAPHIC PRINTERS.

To the EDITORS.

GENTLEMEN,—Mr. Willatt is mistaken in supposing that I view the question of trade unionism for photographic assistants through organizations already formed. If Mr. Willatt will refer to your issues of April and May, 1895; April and May, 1896; May 21, 1897 ("A First-Class Reference"); September 3, 1897 ("The Wages of Photographic Assistants"); also the ALMANAC, 1897, p. 756 ("A Trade Union for Photographic Workers," by Arthur Field); and the ALMANAC, 1898, p. 784 ("Trade Unionism once more"); and my pamphlet, "The Photographic Worker," he will find that my conception of trade unionism is fairly broad. What I do hold, however, is that, whilst the principles of trade unionism are the same in all unions, the particular manner in which these principles are applied must be determined by circumstances. Hence my practical policy is joining the National Union of Shop Assistants, because that union meets our requirements better than any other. This is clearly an indication of what can be done, and not what we should like. In opposition to this, Mr. Willatt advises a "restrictive union," such advice being superfluous, since by its very nature every trade union is restrictive, otherwise it would not be rightly termed a trade union, and the root of this exclusiveness is the "wage limit," which your correspondent coolly drops. I allow that the National Union of Shop Assistants is not so restrictive as the Engineers' or Compositors'. Why is it not? Simply because a smaller percentage of shop assistants are unionists. Restriction thus comes at the end of organization, whilst Mr. Willatt seems to imagine that he can "right off the reel" secure the perfect discipline of engineers or compositors. That idea is a plain

allacy. It is thus idle to remind your readers "that no assistant in photography can at present join a restrictive union." The above union is a real trade union, which will be very evident directly it is in a position to fight out the question of hours, and overtime. At present it confines its operations to provident payments, unemployed benefit, ventilation of grievances, and removal of injustice, and by so doing I think it acts wisely. I have indeed no hesitation in saying that it will do for the photographic assistant all that can be done, things being as they are.

Mr. Willatt's plan of a "general centre," &c., is, I am afraid, very much in the air, just as much as the "Guild of Photography" I sketched out in this column in 1895; something which has yet to take on "a local habitation and a name" I will leave both for, as Amiel said, "the unfinished is nothing."

In strong contrast we see the National Union of Shop Assistants in working order, with a membership of thousands, a balance in hand, and a branch in many of the most important centres, the very fact of its success proving that it is worked on the right lines and meets the needs of its members. So much cannot be said of unions which have been copied from organizations fashioned to meet the wants of other occupations. Mr. Willatt must remember that the conditions which prevail in shops and photographic establishments are feudal and a relic of the middle ages, the photographic assistant once engaged becomes in law and custom the "servant of his master," meaning that, apart from his employer, he has no rights of his own. To meet this peculiarity, a plumbers' union would be useless.—I am, yours &c.,

May 20, 1899.

JOHN A. RANDALL.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

A. England, Triangle Studio, New Barnet.—Three photographs of a parrot and cat.  
W. T. Westhorpe, jun., 34, North-street, Wandsworth, S.W.—Photograph of model frog and beetle boys dressed as frogs arranged in group.

F. W. Urquhart, 3, Balacava-buildings, Dingwall, Ross-shire.—Two photographs of Colonel Hector Archibald McDonald, C.B., D.S.O., A.D.C.

W. JOHNSTON.—The circulation is limited in this country. You might obtain copies of Messrs. Percy Lund & Co., Bradford, or Messrs. Dawbarn & Ward, 6, Farringdon-avenue, E.C., price about 1s. 6d. each.

BROMIDE-ENLARGING.—S. WRIGHT. The enlargement sent clearly shows that the grey lights are caused by light fogging the paper, probably at the time it was being exposed in the enlarging room or camera, or at least at some stage of the work.

STAINED PRINTS.—W. The stains are unmistakably caused by the mounts. The chocolate colour upon them comes off when they are moistened, as with the starch mountant, and thus the print becomes stained while drying. We have rarely seen mounts on which the colour is so soluble.

MEDIUM FOR SPOTTING.—RETSEF says: "I shall be glad if you will kindly inform me where I can get some medium for spotting enamel P.O.P. prints."—Special colours are sold for the purpose, and may be had from most of the dealers. We are unable to say how the makers prepare them.

COPYRIGHT QUESTION.—G. & S. ask: "Can another photographer take a photograph of ours and have it enlarged to 15 by 12, then canvass with it as their own work in the same town as our studio is situated?"—In reply: Yes, if the copyright of the original does not belong to our correspondent.

MOUNTING SOLUTION.—T. FRASER says: "I have made up solution for mounting prints exactly as described on page 1061 of this year's ALMANAC. When cold it is quite solid. Should this be? or should it not be always ready for use?"—Yes, the solution when cold is a stiff jelly, and requires warming for use.

CRYSTOLICUMS.—A. LAMBERT asks "the number and date of the patent that was taken for colouring photographs from the back?"—In reply we ask which patent? Patents innumerable have been taken for this system of colouring, with but slight modifications, at different times. The first, if our memory serves us rightly, was in the fifties.

FORMULA WANTED.—J. BARRY says: "I would thank you to give, in an early issue of your JOURNAL, formula for ferro-gallic paper (water bath only) for plan printing."—There are many formulae, but this is a good one: Ammonio-citrate of iron, 4 ounces; water, 14 ounces; ferrid-cyanide of potassium, 2½ ounces; water, 15 ounces. For use, mix in equal parts and coat the paper. The iron printing processes are very fully treated upon in the ALMANAC for 1889, and by Mr. Lambert in recent JOURNALS.

CLEANING OFF OLD NEGATIVES.—J. WULF writes: "I have a quantity of old negatives I want to clean off so as to use the glass for another purpose. Can you kindly tell me the simplest way to do so?"—Soak the plates in cold water for a day or so, and then put them in hot water. The film will then dissolve off, and the glass can easily be cleaned.

ENAMELLED DISHES.—G. SELTH. Enamelled iron vessels will do very well for photographic purposes provided the enamel is perfect; but if any of the iron is exposed they will not do for silver printing. For carbon work, for which we presume, from the tenour of your query, you require them, they will do quite well even if the enamel surface is not absolutely perfect.

COPYRIGHT.—WANT TO BE SAFE says: "I have seen some excellent photographs of Hogarth's *Industrious and Idle Apprentice*. Shall I be infringing any copyright if I copy these for lantern slides? Is there any copyright in Hogarth's engravings?"—No; but there may be in the photographic copies of them. If you copy the engravings themselves, you will be perfectly safe.

SPOTTY PRINTS.—T. MASON. The comet-like spots or specks are due to minute particles of matter that have reduced the silver where they have come into contact with the paper while in a moist state. Particles of iron, as rust, from the pipes, in the water in which the prints were washed prior to toning, would produce such spots, so would any other reducing agent in a fine state of division.

FAULTY FOCUS.—R. F. says: "Herewith a couple of negatives, taken in a magazine camera, fitted with a —'s fixed-focus lens. You will see they are far from being sharp. Do you think the lens is at fault? Are these lenses good?"—The negatives are anything but sharp, but we should say that is not the fault of the lens, but its being fixed out of focus. Return the camera to the maker for the lens to be adjusted to focus. The lenses in question are in good repute.

AGREEMENT AS ENGAGEMENT.—ANXIOUS says: "I should like your opinion on the following: I have been engaged as assistant to a certain firm in this town for a month on trial. As I do not like the situation, I gave notice at the end of the first week, but the firm in question will not allow me to leave until the end of the month. Now, as I signed no agreement for a month, can I not leave with a week's notice?"—As you agreed for a month, you should stop for that time, and leave at the end of it, unless your employer is agreeable to your leaving before.

LENS COVERING.—B. PRICE. 1. The prints show that the lens has a moderately round field, and, to cover the quarter-plate with a fair definition at the margins of the plate, it must be used with a medium-size stop. A lens with an aperture of  $f/5.6$ , of four-inch focus, must not be expected to cover a quarter-plate unless it be stopped down considerably. Considering the focal length of the instrument, we can see no fault to find with it if it be used for the size it is made for, namely, lantern size. 2. The shutter you have is one of the best in the market, though it is not the most costly. We do not think you would be benefited by making the change.

VERBAL AGREEMENT.—G. R. A. writes: "I am engaged here as an operator on an agreement (verbal) for a year certain at forty-five shillings a week. Have been working a fortnight, and giving every satisfaction. During the time I have learnt that it has been the custom with this photographer—who, it seems, always engages his operators for the year certain—under some pretext or other, to discharge them about October. Can you kindly tell me if I am likely to be served the same, as it is a serious thing to be thrown out of employment just as the winter sets in?"—We cannot say if you are likely to be thrown out at the end of the season, but you certainly are liable to be. Under this verbal agreement you are only a weekly servant, and can be discharged at a week's notice; also you can at any time leave, on giving a week's notice, if any better appointment offers.

BACKGROUND PAINTING.—BACKGROUND says: "Can you give me any information as to what colours are most suitable for distemper painting for photographic backgrounds, and what is the most suitable size to bind the colour? While admitting the necessity for special artists devoting all their time to the production of a certain class of backgrounds, I am of the opinion that, for certain effects, the photographic artist ought to be able to carry out his own ideas in that respect. Any information you can give on this subject will, I am sure, be of general interest."—The colours generally used are whitening and lamp black, with, sometimes, a little Venetian red to give warmth to the colour. The ordinary common size of the oil shops is used for binding the colour. The whitening and black are mixed in water, and the size added hot, and in sufficient quantity to form a tremulous jelly when cold. In that state it is used.

DEVELOPING FORMULÆ.—H. HARBOUR says: "I have some excellent formulæ based on the following stock solutions:—1. Pyro, 1 ounce; sulphite soda, 4 ounces; water to 9 ounces 48 minims. 2. Potassium bromide, 1 ounce; water, 10 ounces. 3. Ammonia, 1 ounce; water, 9 ounces. I desire to use metabisulphite as the preserver of the pyro, and soda instead of ammonia. Will you kindly tell me (in your Answers to Correspondents column), 1. How much metabisulphite should be put to the ounce of pyro? 2. What would be the composition of the accelerator? 3. In what proportion must I reduce or increase the quantities of the developer, restrainer, and accelerator respectively, now given in my formula, that the action may be the same as at present?"—1. The usual proportions are the same weight of the metabisulphite as of pyrogallic acid. 2. Carbonate of soda, 2 ounces; sulphite soda, 2 ounces; water, 10 ounces. 3. This may be used in the proportion of about 1 ounce of No. 2 to each 8 grains of pyrogallic acid, according to the exposure. A large number of pyro-soda developers are given in the formulæ in the ALMANAC.

## EX CATHEDRA.

THE Britannia Works Company have added to their list of manufactures a platinum paper under the trade name of "Platona." They have adopted the well-known Ilford price (1s.) as a basis, twenty quarter-plate pieces in a sealed tin being retailed for 1s., twenty half-plate for 2s. 3d., and twenty  $8\frac{1}{2} \times 6\frac{1}{2}$  for 4s., the other sizes being charged for in proportion. We are informed that Platona paper will be ready for delivery on June 12, and that full formulæ and instructions for development will also be published. The Company have been engaged in the preparation of the paper for several months past, and we believe that, when it reaches the hands of the public, it will be found simple, easy, and reliable in working.

SOME specimen prints on the new paper have been submitted to us, and these show off the always admired qualities of a platinum print to perfection. We anticipate having an early opportunity of putting the new paper to practical trial. This new and enterprising departure on the part of the Britannia Works Company should materially help to further popularise

this most beautiful process, which has been so long held to yield the same of permanence in a photographic print. Any step which has for its object the exploitation of a printing method fulfilling the highest theoretical conditions of permanency in photographic prints deserves support, and we have no doubt that "Platona" will fulfil all the expectations that have been formed of it. By the way, the word "Platona" is a singularly felicitous trade name for the new-comer.

\* \* \*

THE next time the Article Club holds an Industrial Exhibition at the Crystal Palace or elsewhere, we shall not be over-eager to avail ourselves of the "honour" of being present, lest the treatment accorded to some representatives of the Press at Sydenham on Tuesday last should stand a chance of repetition. In the advance news note which accompanied our invitation ticket we were told that a special attraction during the whole of the Exhibition would be the Court of the Biograph and Mutoscope Company. "There will be regularly given up-to-date pictures of what the world is doing. It is expected that a record will be created on the opening day of the Exhibition, as the whole of the opening ceremony, which is timed for twelve noon, will be represented upon the screen before the Royal party leave the Palace."

\* \* \*

WE were naturally anxious to see what was to be seen in animated photography at the Article Club Exhibition, but, in company with many others, our repeated efforts, extending over hours, to gain admission to the room proved fruitless. We believe the Article Club is run in connexion with a weekly contemporary. In that case the slight that was paid to this JOURNAL—we believe among others—on Tuesday last is doubly inexplicable, and we certainly think the Club owes its disappointed guests an apology, which it is to be hoped will be promptly forthcoming. Certainly, in our experience, we have not known of members of the Press being received so disrespectfully as on the occasion referred to, and, for our part, we desire emphatically to protest against such treatment.

\* \* \*

AN adaptation of the cinematograph for advertisement purposes by night has been worked out by Mr. W. I. Chadwick, of Manchester, who has formed a company to exploit it under the title

of Chadwick's Patent Advertising, Limited, with a large capital at command. Some of the very large advertisers have already taken advantage of the system, which is meeting with great success in the northern towns and villages. It is obvious that animated photography for advertisement purposes possesses possibilities that have not yet been tapped, and the method adopted by the Chadwick Company of allowing numbers of persons in different places to view the pictures is one that must commend itself to the attention of business men. Without precisely indicating the plan worked out by Mr. Chadwick, himself an old hand at optical projection, we may say that it is clever and novel, and should be very popular among those to whom it appeals.

\* \* \*

MR. EZRA CLOUGH (Hon. Secretary of the Yorkshire Photographic Union) sends us a list of lectures which are to be placed at the disposal of societies having membership of the Union during the coming session. We must certainly congratulate the executive of the Union both on the alacrity it has exhibited in getting to work in this important matter and the number and variety of the lectures that have been arranged for. If early appearances count for anything, the Union bids fair to have a successful career. So far its proceedings have been prompt and businesslike.

\* \* \*

We append the list of lectures. The figures in parentheses indicate the number of times the lecturer is prepared to repeat his lecture in a session: W. H. Atkinson, "A Night among the Flowers" (3). Godfrey Bingley, choice of the following five subjects, (6): I., "Lantern-slide Making;" II., "North Wales;" III., "The Dales and Coast of Yorkshire;" IV., "London to North Cornwall;" V., "East Anglia and Adjacent Counties." Harold M. Briggs, "Exposure" (3). Harry B. Buckley, "Instantaneous Photography" (3). B. A. Burrell, F.I.C., choice of the following two subjects: I., "Chemicals Used in Photography;" II., "Weights and Measures." Sparham Camp, "Rivers and Broadlands of Norfolk" (3). Fred T. Coupland, "Carbon: Single Transfer" (3). H. Crossley, "Bromide Enlarging" (3 or 4). Rev. W. Hay Fea, M.A., "Holderness" (3). William H. Hainsworth, "In the English Lake District with a Camera" (3). Thomas Heaps, "The Dry Plate: What is it?" (3). J. Hollingworth, M.R.C.S., "Photo-micrography" (2). Alexander Kelhley, F.R.P.S., choice of the following two subjects: I., "Principles of Art Applied to Photography" (2); II., "The History of Photography" (2). J. W. Laycock, choice of lectures below (2 in October): "The Rhone Valley, Rome and Revolutionary France;" "Western France and the Pyrenees;" "The Riviera." Percy Lund, "Some Prominent Photographers and their Work" (2); "Tom, Dick, and Harry, Amateur Photographers" (2); "Trees as Photographic Slides" (2). J. Hudson Lygo, "Carbon Printing, Single and Double Transfer" (3). Samuel Margerison, "What we See in an Old Church" (3). P. E. Newstead, "Some Photographic Types." Arthur H. Ormerod, choice of the following four subjects (3): I., "Recent Advances in Colour Photography;" II., "Orthochromatic Photography;" III., "Cycling and Photography;" IV., "Practical Hand-camera Work." A. Priestley, choice of the following three subjects: I., "Hints on Portraiture;" II., "Bromide Enlarging;" III., "Development for Beginners." J. V. Saunders, M.A., "Knightly Effigies, and How to Photograph Them" (2).

Percy Sheard, "Cairo to the First Cataract." R. Stockdale, "Carbon-process Demonstration" (3 to 6). James Taylor, "Stereoscopic Photography" (3). George Thistlethwaite, "Lakeland, with Cycle and Camera" (3).

\* \* \*

THE June issue of our contemporary, the *Photogram*, is double the size of the ordinary number, at no increase of price, and it is full of interesting and suggestive matter. There are three supplements, a print on Velox, a wall calendar for the month, and an exhaustive index of photographic trade names extending to twenty-four pages. This index must be exceedingly serviceable for reference to all commercially engaged in photography. An article, "The Next Great Step in Photography," is a powerful plea for the every-day adoption of photography in business and private life. Many other noticeable articles complete a singularly attractive number of the *Photogram*.

\* \* \*

MESSRS. CADETT & NEALL, of Ashted, are issuing a little book entitled *Orthochromatic Photography Simplified*, by Mr. Cadett, from which, in another part of this week's JOURNAL, we give some extracts. The use of measured light-filters in conjunction with Messrs. Cadett & Neall's spectrum plates constitutes a very important step in advance in orthochromatic work, and the extracts from Mr. Cadett's essay will serve to enlighten the reader upon the principal points of theory and practice which have been kept in view in working out this scientific system of orthochromatic photography.

\* \* \*

ANAGLYPHOSCOPY is apparently in a way to achieve some popularity in the United States. An American friend has been kind enough to send us some samples of anaglyphs by the Redheffer Art Publishing Company, Chicago. These are coloured half-tones printed on cards. The dissimilar halves of the stereoscopic pair are printed in red and blue inks, and of course do not exactly superimpose. A pair of spectacles having red and blue glasses are provided, and when the anaglyphs are viewed through the spectacles a very fine stereoscopic effect indeed is obtained. The Redheffer Company mark their cards "patent applied for." Of course the anaglyph owes its origin to Du Haeron. However, the idea is so good, and the results yielded so striking, that it is a pity more attention is not devoted to it in this country.

\* \* \*

DEvised by Mr. F. Whaley, the well-known photographer of Doncaster, Messrs. Marlon, of Soho-square, are introducing a system of portable studio screens, which enable the operator to be independent of blinds on the roof. It consists of a series of brass or iron supports covered with light grey fabric, and, owing to an ingenious system of bolts and screws, the screens, which rise to a maximum height of about ten feet, may be fixed in practically any direction up to that height. The screens are opened and set up in a few seconds, and when closed measure six feet by five inches by five inches. They give the operator perfect control of the light, and are exceedingly light and portable.

\* \* \*

By the aid of the Whaley studio screens it is pointed out that the following advantages may be obtained: Either light or shadow can be thrown on any part of the sitter. They can

be used for busts as well as full-length figures or groups, and either the top or side light may be used together or separate, and also for drawing-room portraits. Amateurs can photograph in their own gardens equal to in a first-class studio. They are useful to the artist and the drawing school for lighting any kind of model. Numbers of professional photographers will appreciate the convenience of these screens, which also appeal to many other kinds of artistic workers, with whom easy control of light and shade is a matter of importance.

\* \* \*

ALTHOUGH the session of the Camera Club closed a fortnight ago, the annual Exhibition of members' work will remain on view for a few weeks longer. The Exhibition includes over a hundred photographs, amongst which are some transparencies by Mr. Henry Stevens, photogravures by Mr. Wilmer, and other contributions by some of the best-known members of the Club—Rev. T. Perkins, Henry Speyer (whose Alpine views are remarkably good), Tom Bright, T. Manley, Major Lysaght, Law Bros, R. W. Craigie, in addition to those mentioned in a previous notice.

### STUDIO CONSTRUCTION.

OF the questions, requiring answers in that part of the JOURNAL set apart for the purpose, which are addressed to us week by week, a large proportion relate to studio construction. The suitability or otherwise of a certain aspect of light; dimensions; the most desirable kind of glazing and blinds; the pitch of the roof; the adaptation of existing apartments to studio purposes—these and many other cognate subjects supply the bases of those questions. It can scarcely be wondered that with young professional photographers, particularly those just starting in business, and having little or no experience in portrait work, the provision of a suitable studio by the most economical means is a matter of supreme importance, and consequently it is not surprising that so many questions on the subject should be put to us.

It has probably escaped the notice of many of our professional readers, including those who seek our advice on matters relating to studio construction, that about four years ago a little book on the subject was published by that able writer, Mr. Thomas Bolas. This book is entitled, *The Photographic Studio: a guide to its construction, design and selection of a locality*.\* There is so much sound and useful information on studio building, &c., condensed in Mr. Bolas's book that we shall devote this short article to a recapitulation of its main features. We believe that many of our readers will be glad to know of the existence of the book, and will be induced to take the opportunity of applying some of the valuable hints it contains to the case of their own needs in studio design and construction.

Mr. Bolas's work consists of eleven chapters. An historical and introductory note briefly traces the development of the photographic studio from the days of the Daguerreotype with its long exposures down to the open-area studio, with its glazed side towards the north—the prevailing form of to-day. This form of studio is minutely dealt with in the second chapter, which describes it in its most favourable position, that is, either in the country or the suburbs. The structural details of this particular form of studio, which has its aspect inclined a very little to the east (N.N.E.), are very full, and

are such as would enable the photographer to build an excellent glass house for himself in the rear of an ordinary dwelling-place. Indeed, the chapter, which extends to about twenty pages, is replete with the most practical details. We may here say that the studio described is an actual structure erected by the well-known photographer, Mr. W. E. Debenham.

In his third chapter Mr. Bolas strikes ground over which many a photographer obliged to work in towns will gladly follow him. He deals with the needs of the city photographer, and discusses the best means of adapting confined situations, at the tops of houses, &c., for studio purposes.

Special studios are figured and described in Chapter IV., modifications of the north aspect or open-air studio, and their adaptation to various conditions, with a view to making the best of an unfavourable position, being closely outlined. Moreover, the author is at pains to show forms of studios which are best avoided. This chapter and the one preceding it condense a vast amount of serviceable information which meets the very numerous cases that come before us where photographers in confined places, and having no choice of situation, are puzzled to know how best to avail themselves of the restricted circumstances by which they are governed in erecting a studio in which variety and excellence of effect in lighting are to be obtained.

The tunnel form of studio next comes in for reference, and, incidentally, Mr. Bolas points out its advantages for copying purposes. The south light studio also occupies a separate chapter. Many years ago Mr. Valentine Blanchard erected and successfully worked in a studio having this aspect, and by the aid of diagrams, and quoting Mr. Blanchard's own description, Mr. Bolas shows how this somewhat unusual form of studio was successfully employed.

In succeeding chapters the subjects of curtains, blinds, and screens; heating, cooling, ventilation, and cleaning the glass; municipal building regulations; sash bars and glazing; glass for the studio; illumination and distance, &c., are briefly noticed.

We have said sufficient to show that this little book on "Studio Construction" deserves to be better known by professional photographers than it probably is, and, if in thus directing prominent attention to it we are at all instrumental in making it so, we shall be very pleased. Certainly it meets the needs of a large class constantly seeking information on a vital matter, which has the peculiarity of differing in nature with the individual. The larger and more complex subject of the adaptation of the ordinary dwelling-room to the needs of portraiture does not here come in for notice. It should, however, be borne in mind that we have had only in view the requirements of photographers for the erection of studios for every-day work and it is in their interests alone that we have directed attention to Mr. Bolas's book.

**Rise in the Price of Silver.**—During the last two or three weeks the price of metallic silver has advanced considerably, and it is dearer now than it has been for the last year or two. Photographers are at the present time not so directly interested in the price of silver as they were in the collodion days and when they had to sensitise their own paper for printing. Although the price of silver is now comparatively high to what it has been, it is still considerably less than half the price it at one time was. Now it is varying in price between 28*d.* and 29*d.* per ounce; in the sixties it was quoted as high as 62*d.* per ounce. Not only at that period was

\* Published by Marion & Co. 94 pp. 28 illustrations. Price 2*s.*

the price more than double what it is now, but then it was customary to sensitise the paper on solutions of more than twice the strength that is usual with the majority of those who now sensitise their own papers. This shows that photography was far more costly then than it is now. It also shows that the value of the residues was very different then from what they are at the present time. This fact should be borne in mind by those who complain that the returns made by refiners for residues are so widely different from what they received in days gone by.

**Testing for Acetone.**—The growing popularity of this substance as an addition to the developer renders interesting a lately published method of testing a liquid for its presence. If the liquid be an aqueous one, a small quantity must be mixed with an equal bulk of a mercuric reagent made by dissolving in a test tube 5 grammes of mercuric oxide in a hot mixture of 20 grammes sulphuric acid and 100 of water. The mixture is plunged into boiling water, and, if after ten minutes' boiling no precipitate or cloudiness appears, acetone is not present; if, after a lapse of at least forty-five seconds, a precipitate or cloudiness is seen, acetone is to be assumed as present, the extent of the precipitate indicating the amount present. If a methylic solution have to be tested, a similar programme is followed, but the proportions are equal parts of the solution, methylic alcohol, and water, and double the quantity of the mercury reagent, which must be diluted with water, as the undiluted methylic alcohol when heated is sufficient of itself to precipitate the mercury. If the mixture be an ordinary alcohol, it must be diluted so as not to indicate more than two degrees of alcohol, or the mercuric sulphate arising from the reducing action of the alcohol will be reduced upon boiling. The process is capable of detecting 0.3 per cent. of acetone.

**Aqueous Solution of Metallic Gold.**—In a recent number of the *American Chemical Journal* a remarkable paper is given upon this subject by Richard Zsigmondi. He states that there are various modes by which gold can be dissolved in water with various conditions of colour, but not to the extent to which Carey Lea obtained with solutions of metallic silver; yet deep red, blue, and black were obtained, as well as shades between. The red solution is that to which the experimenter gave most attention. It was made by adding various reducing agents, such as formic or acetic aldehydes, alcohol, or even hydroxylamine, to very dilute boiling hot and slightly alkaline solutions of chloride of gold. The best proportions, arrived at after many experiments, were 25 c. c. of an 0.06 per cent. solution of chlorauric acid ( $\text{AuCl}_3 \cdot \text{HCl}$ ) were diluted with from 100 to 150 of pure distilled water rendered alkaline by the addition of 2 to 4 c. c. of a  $\frac{1}{20}$  normal solution of potassium carbonate; the mixture to be boiling and instantly removed from the flame, and 4 c. c. of one per cent. aqueous solution of freshly made formic aldehyde gradually added to the boiling solution. In a short time the colourless solution darkens, becomes light red, and in a few seconds attains a deep red colour, which does not change in the slightest degree by boiling or after being kept several months. The directions must be strictly adhered to, or the liquid may become turbid or dark purple. The above red liquid may be concentrated, by evaporation, to half its bulk without precipitation, but beyond that concentration a precipitate is produced. By dialysis it may be purified at a temperature of  $40^\circ$  to  $50^\circ$  and still retain its colour when so reduced to one-twentieth of its volume, solutions of 0.12 per cent. being obtained; but this was the extreme possible limit of strength, further concentration resulting in a deposit of metallic gold on the parchment. The liquid may be filtered and is quite tasteless. The similarity between the colours of these solutions of gold and the colours of thin layers of gold by transmitted light is marked, as well as that of rose or ruby glass, the absorption spectra being identical in the two cases. It would appear from this that we here have an excellent medium for filling cells for filtering out the actinic rays from light in a dark room.

**New Monochromatic Light.**—At a meeting of the Paris Academy of Sciences last month, MM. Ch. Fabry and A. Perot described a new and very powerful monochromatic light from an electric current. The light is of the arc type, but the poles are mercury surfaces *in vacuo*, the mercury being contained in two concentric glass tubes and the surfaces being only just separated by the inner tube. A current of thirty volts and two to three ampères is all that is required. The arc is started by giving the arrangement a slight jerk, which ensures a momentary contact, with the usual result of setting up the illumination. The light is not completely pure, but can be rendered so by the interposition of suitable screens; for example, a cell containing a solution of didymium chloride and potassium bichromate absorbs all rays but the green.

**Bequerel Rays.**—This term is now a recognised form of expression to describe those actinic rays given off by certain bodies, and which possess characteristics greatly resembling the Röntgen rays. Professors Elsler and Geitel have been investigating the subject, and sent two papers regarding it to *Nature*. We have, on several previous occasions, referred to them and to Sir Wm. Crookes' theory of their energy being derived from the air, or that it is due to the influence of external radiations falling upon the emitting salts; but the experiments in these papers appear to be adverse to those theories. The authors also confirm the discovery (already described by us) made by M. and Mde. Curie, of certain substances derived from the uranium pitch of Joachimsthal, in Bohemia, which are capable of emitting Bequerel rays of great intensity.

**Discussions at Societies.**—Too often, when a paper is read or a lecture is given on any particular subject, and a discussion ensues thereon, the main point of the paper is lost sight of, the discussion centering on one or two trivial points in connexion with it, sometimes entirely outside it. A case in point was that as shown by our report last week of a recent meeting of the Camera Club, when Mr. Alfred East, A.R.A., gave a discourse on "Art." Mr. East happened, by way of illustration, to give a passing notice of a certain picture with a moon in it. Forthwith the chief topic of a very excellent discourse was lost sight of, and the discussion centered entirely upon the apparent size of the moon when in different positions. When this discussion, on an insignificant point compared with that which was before the meeting, had "pegged out," the meeting concluded with the usual vote of thanks to Mr. East for his lecture, though the main feature of it was ignored. This kind of thing is of too frequent occurrence at society meetings. But whose fault is it? The answer is, chiefly the Chairman's, in not keeping the discussion confined more closely to the main subject immediately before the meeting, and not letting it divert in the way it does frequently into other subjects foreign to the title of the paper.

**Weather Forecasts.**—We have often referred to the weather forecasts as issued from the Meteorological Office. The Meteorological Council have just decided that the issue of hay harvest forecasts can no longer be made gratuitously, but that they will be supplied in the usual form to persons desirous of obtaining them on the payment of the cost of the daily telegrams during the period over which the forecasts are issued; also that, when so requested, the charge for portage will be arranged for by the Meteorological Office, an additional payment being added to the charge for the telegrams. Forecasts also for the wheat harvests will be supplied on the same terms. Judging from the results of previous hay and corn harvests' weather forecasts, as supplied from the Meteorological Office gratuitously, it will be interesting to see, in the next annual report issued by that department, how many have paid for forecasts to be sent them. It would still be more interesting to learn whether they had full value for their money. That, of course, will not be seen from the report. If these weather forecasts were more reliable than they often turn out to be, they would be an inestimable boon to out-door photographers, and would frequently be availed of. At present they are set at naught.

**St. Paul's.**—Evidently the recent agitation by artists and architects has caused the Dean and Chapter of St. Paul's to hold their hands, for we are told by the Press Association that the Decoration Committee has decided that the stencilling should be removed, and that it was desirable, before proceeding to do so, to see what would be the best mode of finishing the arches by completing the south-west dome without any decoration of the flat stonework. It was also agreed at the Committee's meeting that the panels on the fourth quarter dome should not be proceeded with until the Committee have seen the effect of the whole of the south-west section being so treated. Wren's masterpiece is a fine work as it is, and it would be a piece of vandalism to mar it with incongruous "embellishments" or "decorations." But the question is, Does it require any at all? By the way, we, two or three weeks ago, called the attention of photographers to the fact that just now, through the pulling down of some buildings, a view of the Cathedral is to be had from Cheapside that may not occur again. There is a proposal, and it is not a new one, that the north side of St. Paul's Churchyard should be widened and thrown open for vehicular traffic. If that were done, we should thus be able to see our metropolitan Cathedral to much greater advantage. It is doubtful, however, owing to the value of space in the City, if this will ever be done. Unfortunately St. Paul's, like most other fine cathedrals at home and abroad, is so surrounded by buildings that they cannot be seen to advantage, let alone photographed.

**An Old Friend Once More.**—Like the discovery of colour photography, the sea serpent periodically goes the round of the press. This old friend of the paragraphist, so it is said, has not only put in his, or her—sex not stated—appearance in Kilbrannan Sound, but is still continuing its ravages, and fishermen arriving in port one day last week state that the monster followed the skiff, *Puritan*, "fully 100 yards, sniffing and snorting just behind the rudder, and was with difficulty scared off." A harpooning expedition from the port, it is said, is being projected. If such an expedition is carried out, it is to be hoped that it will be accompanied, like most expeditions now arranged, by one or two photographers. Then, if the harpooners fail to secure the monster, the latter may succeed in obtaining a few photographs of this reptile, fish, or whatever it may be. One or two snapshot photographs, if secured, would certainly conclusively prove that our old friend, the sea serpent, was, at least, not a mythical entity. Here is an opportunity for the local photographers of the district to distinguish themselves. The photographs of such a famous thing would certainly command a ready sale all over the world.

#### JOTTINGS.

SHOULD exhibitions of photographs be judged by painters, etchers, black-and-white artists, and so forth? This is an old question that is again engaging attention, in view of the probability of several members of the Royal Academy being placed on the jury for next autumn's Royal Photographic Society's Exhibition. If the rules of the Society included one that debarred non-members from being chosen as Judges, this question would not arise. Personally, I object to painters being set to judge photographs unless they are thoroughly well grounded in practical photography, are conversant with its pictorial achievements, and can estimate its possibilities; they should, in fact, be right in the "photographic movement." Unless they have that special knowledge, they are apt to give decisions which photographers cannot understand, and that dissatisfy as well as mystify them.

My ideal jury would be entirely made up of photographers—such men as Emerson, William Crooke, Walter Barnett, Gale, Mendelssohn, and others who might be named. These men have gone through the mill of photographic study and are still students. They know how to use a lens as a drawing instrument; they have mastered composition, lighting, posing, grouping, all with a view to their

translation by a sensitive surface; they can tell whether a photograph has been "faked," how much is due to multiple printing, Chinese white, the knife, accident, or intention, what the picture owes to the printing process employed, and whether the photographer be a copyist, an imitator, or a man of originality. They, as I have said, are in the movement. Now, your painter has no concern in these things. Once a year, for an hour or two, he looks at a few hundred photographs, gives his decisions, vanishes, and is seen no more for another twelve months. With photography in the sense I have endeavoured above to make clear he does not concern himself.

Of course, I am not censuring those eminent painters who are kind enough to act as Judges of photographs. It is the system that I go for. I am convinced that photography will always be looked down upon until we become a little more self-reliant. Even from the Salon a useful lesson in this matter may be learned. The Dudley Gallery people do not call in outside assistance to do their judging, for, according to the Salon creed, to be hung in Piccadilly is an honour. I can call to mind no other exhibition but that of the Royal Photographic Society which goes to outsiders—presumably non-practical men—for its Judges. On the other hand, I am only too well aware that as possible Judges the number of photographers is very few. There is not a large choice. But the number is not likely to increase while the painter policy is persisted in. Again, I know that many people like initials after the names of Judges. To them a photograph acquires much more value if medalled by five Academicians instead of five photographers. This is a powerful human sentiment, which is hard to destroy. Still the broad fact remains, that there is no real, no insuperable reason why an exhibition of photographs should be submitted to a group of painters for judgment; on the contrary, as I have tried to show, the arguments are all the other way.

It is time photography stood by itself in these matters. So left by the Academicians and others, it might at first be a little unsteady, that is to say, a sufficient number of ideal Judges might be a long time forming, but I believe that in years to come the growth of pictorial photographic knowledge and study would call up a class of cultivated men to whom photographers would have no hesitation in submitting their works for judgment. Now, the longer we rely on the help of outsiders the longer delayed that time will be, and the farther off the hour when photography will stand alone and be respected for itself. This year circumstances were not favourable to the trial of the photographer—Judge; next year, however, with an awakening of the interest of Royal Photographic Society members in the constitution of its annual jury, I should not be surprised to see the agitation against outside Judges reach its only logical conclusion, viz., the election of members only.

The Copyright Bill now before the House of Lords, and the substance of which was printed in the JOURNAL last week, will, if passed, not leave the photographer any worse off than he is at present. Copyright is limited to thirty years, and registration in some circumstances is compulsory; otherwise the present Act is not very materially departed from. The Bill, indeed, interferes so little with photographic copyright, that it is probably best left as it is, except, perhaps, in some matters of detail. It will be noticed that a distinction is drawn between photographs and works of fine art. This distinction probably owes its existence to the Royal Academy. Surely it is a little undignified for photographers, after this, to go hat in hand to members of the latter body, and ask them to sit in judgment on productions which, according to this Bill, do not even come under the classification of "other artistic work!"

Only five weeks separate us from the Gloucester Convention, the programme of which bears an inviting aspect. The West Country excursions and the proximity of the meeting place to London, the

midlands, and the north, should draw a large crowd to support President Cooke. What it is customary to term a good time is sure to result; personally, I hope that, when all the enjoyment is over, photographers of the "bread and butter" kind will be able to congratulate themselves on having materially profited by their attendance, that is, by an increase of their photographic knowledge. The formal and civic proceedings are bound to be interesting, but in the matter of exhibited photography the Gloucester Convention may not come up to some of its predecessors. There are to be fewer papers than usual. The time has gone by, apparently, when men of the eminence of Joly, Rudolph, Hurter & Driffeld, and others could be induced to address the Convention. Such men doubtless feel that their communications would probably not receive notice at the hands of a holiday crowd! However, here's to Gloucester and all that it is capable of being for and to the members of its Convention!

I am sure that there will be a general agreement in the earnest hope expressed by Lord Crawford (p. 319) that the forthcoming *Conversazione* at the Royal Photographic Society's new premises in Russell-square will be the inauguration of a long and prosperous career for the Society. As one whose efforts, both personally and with the pen, have been freely placed at the Society's disposal for several years past, I look forward with peculiar pleasure to taking a share in bringing about the prosperous state of things which the President hopes for. The hearty co-operation of members, Council, and officers will ensure a flourishing future for the Royal Photographic Society, whose well-wishers could desire nothing so much as that strong and harmonious pull-together without which success in undertakings of this character can rarely be obtained.

Ever since the dark days of 1891, when some of the most powerful members of the Society left it, and for a time it looked as if disaster could not possibly be eliminated from the control of its affairs, the influence and advocacy of this JOURNAL have been cast in its favour. Strange as it may appear now, THE BRITISH JOURNAL OF PHOTOGRAPHY was for a long time the only active friend which the Society had in the photographic press. It may, I believe, fairly be claimed that the support thus freely and continuously given has had not a little to do with the growth in favour with the photographic public which has undoubtedly fallen to the Royal Photographic Society in recent years. There was a time, well within my recollection, when amongst photographers up and down the land the mention of the Society's name was sure to provoke a smile, if nothing worse. To-day the case is different. Its membership is respected, its fellowship is coveted.

Only twelve months ago the Crystal Palace Exhibition, the largest and most important undertaking ever ventured upon by the Royal or any other British photographic society, came to a successful end. It appears to have escaped notice during some recent celebrations that the Exhibition was originally suggested by this JOURNAL, and that for nearly two years before it was held the idea received in these pages an amount of unflinching and strenuous advocacy, without which it is doubtful if the Exhibition could have been brought to a successful issue. But such is the irony of Fate, all the credit goes elsewhere, and so apparently do the thanks and recognitions of a less intangible kind.

I have felt it only right that the support which this JOURNAL has rendered to the Society should be placed on record in view of some recent occurrences from which the quality of gratitude was painfully lacking. Fortunately the recurrence of the events to which I am alluding has been placed beyond the reach of possibility. Were it not so, means would undoubtedly have been taken to remove the cause of complaint. I trust this hint will not be wasted, and I hope the responsible officers of the Society will, in future, not allow its warmest friends and supporters to be treated as some of them were a few months ago.

COSMOS.

## THE GLOUCESTER CONVENTION.

### ARRANGEMENTS.

We append an outline of the arrangements for the forthcoming Meeting of the Photographic Convention of the United Kingdom, to be held at Gloucester July 10-15.

**MONDAY, JULY 10:** *Excursion to Elmore, Fretherne, and Frampton on Severn.*—This excursion has been arranged for the benefit of those Members of Convention who are able to be in Gloucester previous to, or early on the morning of Monday.

Conveyances will leave headquarters at 12 o'clock. Luncheon at the Bell Hotel, Frampton, at 2.30. Tickets (including luncheon), 5s.

*Conversazione.*—The opening conversazione will take place in the Guildhall at 7.30, when the members of Convention will be received by the Mayor, City High Sheriff and members of the Corporation of Gloucester. The Convention will be declared open and the President will deliver his address; Mr. R. Child Bayley will give a "Demonstration of Colour Photography," with a short explanation of the various methods employed; and the programme will conclude with an Exhibition of specially selected lantern slides.

**TUESDAY, JULY 11:** *Excursion to Berkeley Castle.*—The Right Hon. Lord Fitzhardinge has granted special permission for the Convention to visit Berkeley on this date, when the general public will not be admitted, and every opportunity will be given to members to photograph the historically interesting Castle and Church.

Trains leave the Midland Railway Station at 10 and 10.55 a.m., and special carriages will be attached to both trains. Luncheon at the Berkeley Arms Hotel at 2.30. Return Trains leave Berkeley Station at 3.15 and 5.22, arriving at Gloucester at 4 and 6.40 respectively. Tickets (including luncheon), 6s.

At the Guildhall at 8 p.m.—A paper (subject to be announced) followed by an exhibition of lantern slides, by members of the Gloucestershire Photographic Society, of places to be visited during the week.

**WEDNESDAY, JULY 12.**—The Annual General Meeting and Election of the New Council at the Guildhall at 10 o'clock. After the meeting the members will adjourn to the Spa Cricket Field, where the Official Convention group will be taken by Mr. A. H. Pitcher at 12 noon.

At 2 o'clock a visit will be paid to the Cathedral, when the Dean hopes to be able to receive the members and conduct them over the building. The usual visitors' fee, 6d. each, will be charged (N.B.—The visitors' contributions are in aid of the restoration fund).

*Annual Dinner and Smoking Concert.*—At the Bell Hotel (head-quarters, at 7 p.m. Evening dress optional. Tickets (not including wine), 5s. 6d. Ladies are invited to be present at the dinner and concert.

**THURSDAY, JULY 13:** *Excursion to Chepstow, Tintern, and Symonds Yat.*—Trains leave Great Western Railway Station at 9.29 a.m., arriving at Chepstow at 10.20. A special train leaves Chepstow at 12.30, arriving at Tintern at 12.45. Trains leave Tintern at 3.8 and 6.51, arriving at Symonds Yat at 3.52 and 7.36 respectively. Train leaves Symonds Yat at 8.33 arriving at Gloucester at 10 o'clock.

Luncheon at the Beaufort Arms Hotel, Tintern, from 1 o'clock. Tickets (including luncheon and admission to Chepstow Castle and Tintern Abbey), 7s. 6d.

There will be no meeting at the Guildhall on this evening.

**FRIDAY, JULY 14:** *Excursion to Ashleworth, Deerhurst, and Tewkesbury.*—The steamer, *Avonmore*, which has been specially engaged for this excursion, will leave Westgate Bridge at 9.30, calling at Ashleworth and Deerhurst. The time of the departure of the steamer from each place will be posted up at the gangway. Fare, 6s., including luncheon and admission to Saxon Church and Chapel, at Deerhurst, and Tewkesbury Abbey, with permission to photograph at both places.

At the Guildhall, at 8 p.m.—A paper on "Binocular Vision and the Stereoscope," by Mr. Thomas Bedding, F.R.P.S. Followed by an exhibition of specially selected lantern slides.

**SATURDAY, JULY 15.**—Various short Excursions to places in and around Gloucester (as may be required) will be arranged for this day. Among these may be mentioned Highnam, Matson, Hempstead, Cheltenham, Ledbury, Forest of Dean, &c. For particulars see notice boards.

*Bath.*—Should any members desire to visit Bath on their road home, special facilities will be afforded for them to take photographs of the Bath, Roman remains, St. Mary's Abbey Church, &c. Mr. G. F. Powell, 25, Green Park, Bath, a member of Convention, has kindly promised to supply any further information on the subject, and all communications with regard to this matter should be addressed to him.

## IMPORTANT PHOTOGRAPHIC PROBLEMS THAT REQUIRE INVESTIGATION.

(Paper read before the London and Provincial Photographic Association.)

AFTER looking at the marvellous results of modern photographic work, one would almost wonder that there could be such things as any problems requiring investigation.

The speed and quality of our plates, and the perfection to which the manufacturers have brought their printing papers, are such that one can hardly realise that, from a scientific point of view, such a small advance has been made in our knowledge, during the past fifty years, upon such subjects as the action of light in the formation of the photographic

image, or of what that image consists, and the question arises, "Are our photographic societies, especially the parent society, carrying out their duties when they allow such important problems to drift on year after year without, at least, some slight attempt at a systematic organized investigation on a thoroughly scientific basis?"

Of late years an attempt has been made to claim for photography a place among the arts, and to ignore its scientific basis almost entirely by placing the emulsions and printing papers on the same level as the colours of the artists' colourman.

Artists contend, and contend most truly, that photography is not, and never can be, an art. There is as much difference between photography and art as there is between the verbatim reports of our police courts and those marvellous examples of literature in which Sir Walter Scott threw a halo of romance over Scotland and her people. It is true that occasionally the police court will give us a character that, for true nobility and grandeur, the novelist cannot equal. So the camera will now and then produce an effect of light and shade that no artist could ever compete with, but in both cases the bulk of the pictures of life from the police courts and the representation of nature in our photographs have too heavy shadows.

Art is nothing more than dreamland, and an artist is a man who reproduces in his waking moments not what he really sees, but what it appears in the fantastic dreams of his imagination. But photography has done a great work by dragging art out of the sea of falsehood in which it was engulfed in the past. Before the days of photography few people really used their eyes, they accepted the artist's false drawing as correct; but directly the photograph began to teach the world the true representation of form then began a silent revolution in the art world, and there is no doubt that, from an educational point of view, photography has done a great work, because it has not only taught the artist correct drawing, but it has trained every one, from the Board-school child upwards, to use their eyes, and detect the difference between the true and the false in the representation of form.

We will now look at photography from a more scientific standpoint, and, first, as to "light" itself in connexion with its action on the photographic plate according to the absorption theory of light. In passing through a transparent medium, the molecules of the latter take up the waves of certain periods, and the remainder pass through, giving the colour of the medium. Now, if we take a plate coated with a slow emulsion (one that used to give a good ruby colour in our old emulsion-making days), one can understand that the blue and more actinic rays taken up or absorbed in the film have been converted into the light action that has taken place on the particles of silver bromide, and that the slow vibrations are allowed to pass through, thus giving the ruby colour transmitted through the film. In this case theory seems supported by practice; but how about a rapid emulsion that transmits blue rays? The molecules of this film have taken up the waves of the slow period, and yet we obtain a much greater speed of plate, although the more rapid vibrations of the blue or actinic rays have passed through the film. How can we explain these slow vibrations, absorbed or taken up in the film, acting more rapidly on the particles of silver bromide?

When we photograph the spectrum, we have even greater difficulties to explain. If we throw a spectrum on a screen, and look at the blue portion through a piece of blue glass, we find that the glass stops those rays very little, in other words, it is transparent to them. And yet we know that, if we take a rapid plate which transmits blue rays, the blue rays in the spectrum to which the plate ought to be most transparent have been most active in their action on the silver bromide particles. Some one may say that it is because their action is based on a similar law of vibration to that of a tuning fork, which will communicate its vibrations to another of the same note. But, if that is so, why do not the red rays of the spectrum act more strongly on a slow film transmitting red or ruby rays than those at the blue end of the spectrum? I think you will agree with me that we have here a problem requiring investigation.

I now come to the question of the action of light on chloride of silver, on which are based our printing-out processes. The first thing we want to know is, of what does this photographic image consist? If we take some pure chloride of silver with a proper excess of silver nitrate, and expose it to light, we will find that it will assume a slate-blue tone and refuse to bronze; and, if it is treated with hyposulphite of soda, it will be almost entirely dissolved away. So our photographic image is not metallic silver from the reduced chloride of silver, indeed the only part the chloride seems to play is that of an accelerator in the formation of the image.

But, if we add some organic matter to the chloride of silver and expose it to light, we shall find that it darkens usually to a dark-brown hue, and then becomes bronzed, which colour is comparatively unaffected after fixing. This shows that the image consists of silver combined with coloured organic matter. We now want to find out how much silver there is in this compound.

I think the best way to do this is to take a sheet of albumenised paper, and, on sensitising it, we shall find that it will take up about twenty-eight grains of nitrate of silver. We will then expose it to light until it darkens all over to just short of the bronzing stage. Then, if we treat it as an ordinary albumenised paper print, we shall find in the washing

waters about 14 or 15 grains of the silver, in the fixing bath another 10 grains or so, in the washing water after fixing about 2 grains, and in that blackened sheet of paper measuring 23 x 17 inches there will be barely a grain of silver left in the deposit.

That being so, can we call it a silver image at all? The fact appears to be that it is coloured organic matter produced by the action of light on the silver in which it had previously been in combination; and that, after the formation of that coloured deposit, about 97 per cent. of the silver can be removed, although the whole 100 per cent. was necessary to produce it. If this is so, the next question is, What is the action of the gold of the toning bath? Is the gold simply deposited on the organic matter forming the image, or does it keep some of the silver from being removed in the hypo bath?—in other words, is the greater permanence of a gold-toned print due not only to the presence of the gold deposit, but to a locking-up (so to speak) of some of the silver as well? I think this is probably the case, and that some of the sub-chloride of silver is formed into an insoluble hyposulphite of silver, which is not redissolved in the excess of hyposulphite of soda in the fixing bath.

I think the following experiment will show this. If we allow sulphuretted hydrogen to act on a print, it will at first slightly darken the image until the bleaching of the organic matter commences. This same darkening action by sulphuretted hydrogen takes place on sub-chloride of silver that has been treated with hyposulphite of soda.

As far as the permanence of the image is concerned, this extra silver is of course an advantage, but, unfortunately, I have found that the yellowing of the whites in old albumen prints is, in many cases, due to their having been in a toning bath. The gold prevents the whole of the silver being removed by the hypo from the white parts of the print, and the sulphuretted hydrogen in the atmosphere slowly converts this silver into a yellow sulphide. If you will make the following experiment, you will find that this is so. Take two pieces of sensitised albumen paper, and, without any exposure to light, wash them to remove the free silver nitrate. Then soak one piece in a toning bath for ten minutes, then fix and wash both pieces in the usual way. Now, if you expose those two pieces of paper to the action of sulphuretted hydrogen, you will find that on the one that has been in the toning bath there is a formation of yellow sulphide of silver, showing that the gold had prevented some of the silver being fixed out in the hypo bath, whereas the one that had not been in the toning bath has kept its purity of colour.

We often see in the text-books that it is best to tone before fixing; but if the gold prevents the whole of the silver being removed from the whites of the print, and is the cause of the faded yellow photographs we so often see, would it not be better to fix first, to remove the silver, before depositing the gold on the image?

I need hardly point out what an important matter this is to the professional photographer, and what is required is for somebody (say the London and Provincial Photographic Association) to start a regular systematic and scientific investigation into the whole subject; because, after all to get the best results, we must have a printing-out process.

Photographs by blind processes requiring development, or semi-blind like platinum, are very fine when everything is just right. But the waste of material is, and must be something enormous, for the professional man to turn out only the very best work.

So far I have only spoken about light and the visible photographic image. I now come to the subject of the latent image requiring development. We will take the old wet-plate negative first. Here we have a collodion film, mainly on the surface of which are particles of bromide and iodide of silver, with an excess of free silver nitrate. After exposure to light, development causes a building up from the free silver nitrate of an image upon the particles of silver bromide which have been acted upon by light. It seems to me that the sub-bromide theory explains this action very well, although even in this case we find that the physical characteristics of the film have an important bearing on the speed of the plate, the high or low-temperature cotton, and the amount of alcohol used in the collodion, all having a controlling action.

But, when we come to consider the dry plate with alkaline development, all the old theories are topsy-turvy directly. Everything is on an entirely new basis. So far as the particles of washed silver bromide are concerned, the alkaline developer will reduce those which have not been acted upon by light as rapidly and perfectly as those which have been. Then we have to explain reversal of the latent image. It is of no use guessing that the action of light is a chemical, a physical, or an electrical one, unless we can explain reversal as a natural sequence. We have to explain, first, a latent negative image, then a latent positive one, then a visible negative deposit. We have here no building up of an image from the silver in other parts of the film. Every particle of washed silver bromide imbedded in the film of gelatine or collodion has to act on its own account. It has first to be bound up or protected from the action of the developer by the film. If it were not for this protection by the gelatine, dry-plate photography would be an impossibility with alkaline development.

What the actual momentary action of light on a particle of silver bromide is it is almost impossible to say. All we can really say is that, by some means, the protective property of the gelatine over it has been destroyed, and the developer is able to reduce it. As many of you

know, my own impression is that there has been a vibration of the atoms of bromine and silver sufficient to destroy the protection of the gelatine surrounding them, but not sufficient to free the bromine.

If the light action is continued, we obtain reversal, i.e., something has occurred to again prevent the developer reducing that particle of silver bromide to a metallic state. It is no longer a question of the physical protection of the gelatine, that has already been destroyed. What I believe does take place is a chemical action, viz., a reduction of the particle to a sub-bromide. The over-exposure to light, producing a continued vibration of the atoms, has caused the liberation of the bromine, which combines with the gelatine immediately surrounding the atoms of silver, and then this bromine acts as chemical restrainer or protector against the reducing action of the small amount of the developer that is able to soak into the film; and thus we obtain reversal. Of course, the reason we cannot get the amount of density on an over-exposed plate is because there has been a reversal of some of the particles of silver bromide. The silver is in the film to be reduced to a metallic state, if we could only clear the free or liberated bromine out.

There are a great number of other problems requiring investigation, but I will only refer to one which may be taken up by those who are interested in the pictorial aspect of photography rather than the chemical.

Although photography can never be an art, it does not follow for one moment that it will not produce a pleasing, and even artistic, representation of nature. I do not mean the miserable, dull, gloomy, depressing examples found in our exhibitions during the last few years. For instance, the Salon would make a most suitable meeting-room for a club of undertakers—that is, if the average type of female beauty exhibited in the portraits did not scare the members away. To see these exhibitions, one would think there was no such thing as light and sunshine. What we want, for a change, are pictures with a mass of light half-tones, and with only a few intense shadows to give brilliancy. Most photographs suffer through the darker half-tones being too heavy. The best way I can see at present to get over the difficulty is to develop only to that point where the deepest shadows in the negative would remain clear glass when fixed, and then intensify the image heavily. What we want is to raise the scale of half-tones in the print away from the deepest shadows.

HERBERT S. STARNES.

#### ORTHOCHROMATIC PHOTOGRAPHY: A SIMPLE EXPLANATION.

If we examine the spectrum of white light and make a curve showing the luminosities, or eye values of the various parts of the spectrum (as, for instance, Captain Abney has done), we shall see how a perfect photographic plate should behave. Except for special purposes, we require for pictorial work plates which will photograph what the eye sees and nothing else, and they should give densities of image the opacities of which are proportional to the light intensities of the object as they appear to the eye, no matter what the colours may be. The curve of sensitiveness of an ordinary dry plate to the spectrum of white light, compared with the luminosity curve of the same spectrum, shows a difference so astounding that at first we wonder how photography can give any representation worthy of the name at all; indeed, were it not for the considerable amount of white light reflected by nearly all coloured surfaces, the use of photography for pictorial representation would be scarcely possible; nevertheless, the want of orthochromatism, or luminosity sensitiveness, is serious in many ways. Ordinary plates do not sufficiently distinguish the luminous value of blue sky from that of white clouds; and the greens and reds of our landscape which predominate in mixtures of white, to define colour, receive no adequate representation on the plate, and by the time the rays which do affect the plate, reflected by the objects of our landscape, have done their work, the skies are "burnt out" with over-exposure. More particularly is the want of orthochromatism felt in photographing close objects, especially those giving brilliant colour effects, because in ordinary portraiture the hideous spotty faces of untouched negatives are mainly due to want of orthochromatism, and the retoucher's art, though sadly abused, becomes a necessity. In photographing flowers or paintings, a brilliant red or bright yellow will often show as a dark patch in the print, while a deep blue will be represented as nearly white, the impression on the plate giving a result quite contrary to that seen by the eye.

All plates are sensitive to the visible rays of the spectrum, but such sensitiveness is widely different from the luminosity curve above referred to; the plate is also sensitive to rays of the spectrum which the eye cannot see, particularly in the ultra-violet. In practice, photographs are taken entirely with the blue, violet, and those ultra-violet rays which the lens will pass; the simple reason is that the ordinary plate is much more sensitive to these rays than it is to those of the green and red, so much so that in photographing the spectrum you may get full density and even considerable halation at the blue or violet part, without any action worth speaking of in the green and red parts. Practically speaking, we are only taking a picture of the blue and ultra-violet rays from the object.

The eye is a poor analyser of colour; if we take bright reflected pigment colour for instance, the spectroscopic will show us all the colours of the spectrum, because pigment colours and those of natural objects are

more or less always impure, but the predominating colour intensities decide the colour estimation.

We may add considerable quantities of white light to any colour giving rays without altering the colour impression, though the eye is very sensitive to the increased luminosity occasioned thereby.

Colour is merely a physiological effect, quite apart from luminosity, though to the eye a certain luminosity is necessary in order to differentiate colour at all; but the same might be said, of course, as regards even seeing anything. It is possible to have any colours of the same luminosity, for instance, a red or yellow may be shaded to the same luminosity as a deep blue; in fact, in light and shade any colour may be of any luminosity within the limits of the light used for illumination. For the same degree of illumination of white light the primaries, red, green, and violet, are, of course, less luminous than their complementary compounds, blue, pink, and yellow, these being double sensation colours as compared with the primaries. It is necessary to mention these facts in order to clearly understand the requirements of orthochromatism.

No so-called orthochromatic plate is or need be colour-sensitive; the popular error on this point is fatal to clear comprehension. It is a question merely of sensitiveness to certain wave-lengths of light; the plate is absolutely colour-blind, or colour-insensitive, but it must be sensitive according to the luminosity of the light, no matter what the colour may be. Suppose we have a red light of ten luminosity and a green of ten luminosity, the plate under these circumstances must be equally sensitive to both, and for the same exposures give equal densities for both the green and red, simply because the luminosities are equal. The same, of course, applies to any colours. Colour has, therefore, nothing to do with the plate; the fact that certain wave-lengths of light are red, green, or violet, to the eye is a mere physiological condition.

From this we can see that colour contrast can never be rendered in monochrome. Many artists of ability talk nonsense when they say that it can. Suppose in a picture we have a red and a blue of equal luminous intensity side by side, which are you going to represent in monochrome as lighter or darker, considering that the luminosities are actually the same? The artist will tell you that you must differentiate, but, if you alter the luminosities, your balance of light and shade is no longer the same as in the original; and this, unfortunately, applies to the whole of the picture. It is clear that, unless the relative spectrum sensitiveness of the plate can be brought in accord with the relative spectrum luminosity to the eye, any attempt to correctly reproduce light and shade is hopeless. In copying works of art in which coloured light and shade have to be represented in monochrome or black and white, it surely is clear that, as reproduction in colour is denied us, light and shade are all that is left. We can at least reproduce them, but, if we attempt to delude ourselves into the idea that colour simply can be represented by alterations in luminosity, we end in producing a result which neither renders colour nor light and shade as in the original. Every coloured picture consists of two different contrasts—those of colour, and those of light and shade; if we take away the colour contrasts, we have the light and shade contrasts left, which can still be faithfully rendered. In speaking of light and shade contrast we mean both the light and shade of natural objects and the representation of light and shade by the pigments of the artist. The whole matter resolves itself merely into the correct rendering of luminosities quite apart from colour.

It is probable that the false idea that colour contrasts may be represented by luminosity contrasts has arisen through the meagre education the artist usually has on "light," and one of the first things he does is to compare the luminosities of the various parts of the spectrum of white light, and as the result sets out the order of luminosities of the various colours. This would be all right were there no such thing as shade. When we have, as is always the case, the complex conditions of colour contrasts together with light and shade contrasts to deal with, it is easy to see that it is not only possible for any two colours to have the same luminosity, but that the order of spectrum luminosity may be actually reversed. A shaded yellow may have less luminosity than a better lighted blue or violet, and so on. In consequence, if we wish to preserve the light and shade contrasts of the original, the question of colour contrast must be set aside if our rendering be in monochrome or black and white. If we attempt to reproduce both colour and light and shade contrasts, we attempt an impossibility and get neither, unless, of course, we print in colours. This brings us back to our statement that colour contrasts cannot be rendered in monochrome or black and white, and therefore, if we give up colour, we may still render correctly light and shade.

It is fortunate that the complex mixtures of light forming our pictures of nature and paintings enable us to effect a compromise to overcome the imperfections of the plates and screens. For instance, if we photograph the spectrum with both plate and light-filter, we at once see the theoretical faults of both, while the rendering of pictorial work may be sufficiently good to entirely satisfy the eye, owing to mixtures of light making the errors fractional. To those who scorn the aid of the spectro-scope, and there are many such, we would say, When you can photograph the visible spectrum perfectly, you can photograph everything perfectly also, that the eye can see.

Once more we would urge every one to remember the simple fact that colour contrast is totally different to light and shade contrast.

These remarks are necessary because certain firms who photograph paintings say that they will not be able to use correctly screened plates. Fatal mistake! If your plate be not truly luminosity-correct, the harmonious rendering of light and shade of the original will be lost, and the result will be blotchy and untrue.

How far have we advanced in the twenty-six years which have elapsed since Vogel's discovery? Until recently, not very far. The progress of scientific photography must necessarily be slow, as some of the most difficult problems of chemistry and physics have to be dealt with; indeed, it is most galling to the photographic chemist to find how little he knows of the chemical and physical conditions of the materials he uses.

We are still very far from perfection as regards orthochromatic plates. Excepting for representation in colour by the various colour printing processes, no plate, with any pretension to perfect representation of luminosities of whatever colour, should require a light-filter at all. A plate should be sensitive only to the visible rays, and proportionally render the intensities or luminosities of such rays without any regard to colour. Unfortunately, up to the present, no method of sensitising films or emulsions will raise the sensitiveness of the green and red portions of the spectrum sufficiently to equal the light action relatively to luminosity of the blue and violet portions, so we have to use light-filters to cut out the useless ultra-violet, and tone down the blue and violet and various amounts of the green or red, as the case may be, to counteract the imperfection of the plate and compel it to render all luminosities proportionate to their intensities.

JAMES CADETT.

## PRACTICAL NOTES ON SOME IRON PRINTING PROCESSES.

### PART IV.—BLACK-LINE PROCESS (*Ink Process*).

#### *Ferro-gallic Process.*

THE credit of originating this process is generally given to Poitevin, who made a public communication in 1859. In 1880 Riegel published a formula, in 1883 Colas gave another. Shewcross and Thompson, in 1885, took out a patent for a paper of this character. Senzig and Mellis have also made communications on the subject.

The general outline of the process may be compared with that known as Pellet's, with the conspicuous difference that gallic acid is now used (in place of potassium ferrocyanide) for development. The ferro-gallic or black-line process is sometimes called the ink process, but this latter term is preferably applied to a somewhat different printing method described in the next chapter.

The general opinion seems to indicate that the strength of the developer should be adjusted to the proportions of sensitising materials; therefore it will be more convenient to have the coating and developing formulae side by side.

#### A.

1. Ten per cent. solution of gelatine.

#### B.

Ferrous sulphate.....	20 parts.
Tartaric acid .....	40 "
Ferric chloride .....	45 "
Water .....	400 "

Mix while warm, and coat the paper at once.

#### *Developer.*

Oxalic acid .....	1 part.
Gallic acid .....	7 parts.
Water .....	1000 "

2. A.—Soak 35 grains of gelatine in 1 ounce of cold water until quite soft. Then dissolve by placing the containing vessel in a dish of warm water.

B.—Of tartaric acid, ferric chloride, and ferrous sulphate take 20 grains of each, and dissolve in 1 ounce of warm water.

Mix A and B while warm, and apply at once.

#### *Developer.*

Oxalic acid .....	20 grains.
Gallic acid .....	100 "
Water .....	1½ pints.

3. A.—Dissolve 150 grains of gelatine in 4 ounces of water.

#### B.

Iron protosulphate .....	150 grains.
Tartaric acid .....	150 "
Iron perchloride .....	300 "
Water .....	7 ounces.

Mix and coat the paper.

Develop with—

Oxalic acid .....	20 grains.
Gallic acid .....	120 "
Water .....	40 ounces.

4. Zinc sulphate.....	5 parts.
Tartaric acid .....	5 "
Ferric chloride .....	12 "
Gelatine .....	5 "
Water .....	25 "

#### *Developer.*

Gallic acid .....	5 parts.
Methylated spirit .....	50 "
Water .....	300 "

5. Ferrous oxalate.....	10 parts.
Tartaric acid .....	20 "
Ferric chloride .....	30 "
Water .....	240 "

Mix this with an equal quantity of a ten per cent. solution of gelatine.

#### *Developer.*

Oxalic acid.....	1 part.
Gallic acid .....	8 parts.
Water .....	1000 "

6. Iron persulphate .....	10 parts.
Tartaric acid .....	10 "
Gelatine .....	10 "
Ferric chloride .....	20 "
Water .....	300 "

#### *Developer.*

Gallic acid .....	20 parts.
Alcohol .....	200 "
Water .....	1000 "

### HELIOGRAPHIC PROCESS OF FISCH.

#### A.

7. Iron persulphate .....	8 parts.
Water .....	20 "

#### B.

Tartaric acid .....	5 parts.
Water .....	50 "

#### C.

Gum arabic .....	5 parts.
Water .....	50 "

Add A to B, then add C, stirring well.

Then add 10 parts of saturated solution (45 Beaumé) ferric chloride.

#### *Developer.*

Oxalic acid .....	1 part.
Tannic acid .....	20 parts.
Water .....	1000 "

The sensitising solution keeps for some time if stored in the dark.

### 8. NAKAHARA'S PROCESS:—

Gum arabic .....	15 parts.
Water .....	110 "
Tartaric acid .....	2 "
Sodium chloride .....	9 "
Iron sulphate .....	10 "
„ perchloride .....	15 "

*Developer.*—A plain aqueous solution of gallic acid; the exact strength is not of much consequence. If it be too strong, or the prints are left in it too long, the paper becomes stained.

For this process a highly sized paper is recommended. The sensitising preparation should be mixed in the order given above. The paper should be evenly coated and quickly dried. After development the washing should be quickly and thoroughly done.

*The Paper.*—Firm and highly sized paper is the best. Hard drawing paper—Saxe, Reeve, &c.—may be used. Sizing may be done with insoluble gelatine, arrowroot, &c. The less porous the paper, the brighter is the result.

*Coating.*—The paper may be floated, or preferably coated, by using a Blanchard or Buckle's brush, or a soft, clean sponge, &c. Evenness of coating is of importance. Quick drying is also highly desirable. The following plan is strongly recommended for large sheets of paper: Using a clean sponge, thoroughly damp one side of the paper evenly all over. Allow a short time for the surface to get thoroughly wet, then wring out the sponge as dry as possible, and with it remove all the fluid possible from the surface of the paper. The paper must, of course, be dried in the dark and stored in a dry place. It will keep fairly good for about a fortnight.

*Printing and Exposure.*—The paper has a greenish-yellow appearance. The action of light removes the colour, so the design is white on yellow ground. The exposure varies with the make of paper and sensitising solution. An average exposure in good sunlight would be about ten or fifteen minutes.

To render the visible effect of printing more conspicuous, you may add to the sensitising solution a small quantity of a saturated solution of potassium sulphocyanide. This gives the paper a red colour, and, as this colour bleaches out on printing, the contrast of printed and non-printed parts is accentuated. Some workers suggest that a small negative of about the same strength be put out side by side with a large one, and that the test strips be withdrawn from time to time from the small test negative, and that these test strips be brushed over with potassium sulphocyanide solution, which will indicate how far the printing has proceeded.

Under-exposure is indicated when the paper under the clear part of the picture is tinted in development. Over-exposure is indicated when the parts under the dense portions of the positive (or transparency) are broken up or granular. Ferrogallic paper is not usually so quick printing as the Pellet paper, but is quicker than the ferropurssiate paper.

Development is done either by floating the print face down or immersing it. Prolonged action of the developer is apt to stain the whites of the paper, especially if the printing has not been thorough. Some workers develop with gallic acid—a weak solution, to which is added a small quantity of alum.

After development, the print requires very thorough washing. Place between clean blotting-paper and dry. (If the paper is not blotted fairly dry, the lines may run.)

The first washing water after development should be slightly acidulated with oxalic or sulphuric acid.

REV. F. C. LAMBERT.

### THE NEW SEASON.

EASTER is usually about the commencement of the photographic season, when apparatus is overhauled and put on trial for the anticipated work we each, after our own fancy, have elected to pursue. Most photographers have pet subjects of some class, in which they succeed better than with another; but, whatever it may be, sunny, genial weather conduces to its better performance than do the chill blasts and grey skies of winter. That photography, to be enjoyed, must be practised in quiet, pleasant weather, is pretty generally allowed. Although some enthusiasts profess a liking for stormy seasons and grey days, they form a decided minority.

We generally formulate some programme as to what we will do early in the season, to be more or less modified according to the vagaries of this tantalising climate. For my own part, I may say that, if I fix on some special subject for some special time, it rarely comes off according to programme. There is, however, a class of photography that may be fairly well arranged for in advance, and that is interior work. Fortunately, the early spring months, before the attractions of foliage make one long for work in the open air, are the best for it, the light in March, April, and May being far better than later on in the summer, although this is much less important now than in the days of wet collodion, when the best light procurable was a *sine-quid-non*; but even now a good and proper light will be found to produce much the best quality of negative, although there may perhaps be as much detail in one taken in a poor light as the other. A good light gives a creamy richness that makes a good printing negative that a poor light fails to do; the development also goes smoother and nicer than when shadow detail seems tardy in showing itself. Interiors which have to be taken in cold spring weather, of churches and suchlike places, are subject to a special annoyance in the form of smoke from the warming apparatus, which very often fills the building with a haze that renders a good photograph impossible; the worse the light the more influence the haze has, as may be readily imagined, reducing the contrasts very considerably.

To get a good negative of an interior it is imperative that haze shall be absent, whatever the cause of its presence may be. In very dry weather a haze is often caused by cleaning and dusting operations, which are of periodical occurrence in most buildings frequented by the public. A little inquiry beforehand will indicate which days are most likely to be free from the trouble, and we can make our arrangements accordingly. The air being generally moister in the spring months lessens this grievance, and for this reason interior work is better done then than in hot, dry weather.

Outdoor work is, however, the kind more generally practised in summer time, when not only photographs can be taken, but the scenery enjoyed and our health improved, for, unless the work is strictly professional, it is only indulged in as a pleasant recreation to give variety to a holiday, and as such has everything to recommend it. The display of some speciality at our annual exhibitions that has attracted favourable attention has probably some considerable influence in deciding us on the class of photograph we will try to make; but, in doing this, it is all very well to try for a *similar effect*, but not to make a *similar picture*. Slavish copying of other people's work is to be altogether reprehended. Let the individuality of the worker be shown in his work. The hazy, out-of-focus pictures we have been inundated with of late years, because one or two clever pictures were produced by clever men, who knew how to produce pictorial effect and adopted the particular treatment to gain it, caused many to copy the style, but utterly fail to secure artistic effect, with the result of flooding the exhibitions with meaningless rubbish. I

fancy, however, this craze has somewhat subsided, and in the future we shall have photographs that will not only be pictures, but show how our opticians have worked to permit us to make them. Not by any means that I am an advocate for photographs made to show off what an instrument can do in a purely technical sense, for its powers should be utilised without in any way distracting the attention from the picture formed by its aid. *Ars celare artem* is an axiom as good in photography as anything else, for very often those who are so scrupulous about technicalities fail to make pictures; but, when the two qualities are combined—good technical skill and artistic ability—we may safely expect a photograph, in every sense of the word, above the average.

Of all unsuitable media photography is perhaps the most so for the production of impressionistic work as it is termed; the very character of a photograph is the perfect antithesis to anything of the kind, and to produce a result of this sort worthy a passing glance is a mere matter of accident, a thing not to be repeated at will and of very questionable advantage at the best, accident or not. Like many other matters, we rush from one extreme to the other, in this case from microscopic definition to none at all. Perhaps, having reached the extreme of fuzziness, we may oscillate back to our original ideas of photography; but, with the advanced knowledge of art, the probability is we may stop at the happy medium and produce pictures that will not provoke hostile criticism for one quality or the other, at any rate it is to be hoped so.

A great many conditions that our opticians have succeeded in mastering in the construction of a high-class lens are but occasionally required in ordinary outdoor work, but that they are available when they are required is an unmistakable advantage. A good single lens is not to be beaten for the usual landscape work; the photographer provided with several of this kind, of different foci, there is very little outdoor work closed to him. Of course, for architectural pictures rectilinear lenses are necessary; but even such subjects as these, provided the lens is worked well within its full capabilities, can be correctly rendered by the single lens. In some compositions a lens giving a perfectly flat field is less useful than one not so accurately adjusted, and will render an arrangement of material in a concave form, so to say, better, with a larger stop than the other with a flatter field. Single lenses are, however, limited in their usefulness, as a row of buildings, say, the one side of a street, taken from the other side, would show a distinct curvature of the horizontal lines, although the vertical ones, being shorter, would not be noticeably distorted unless they completely filled the plate. Of course, the more broken and varied the lines of a building, the less a slight curvature shows. The photographer must therefore use discretion in his selection, and by doing this many pictures may be taken creditably with the single lens that might be thought to be beyond its capabilities. Very few, if any, ordinary landscapes require microscopic definition, the time when such definition is perhaps an advantage is in small work for lantern slides or when an enlargement of some kind is needed. I am under the impression that the many refinements of our best modern lenses are but indifferently appreciated by the majority of landscape photographers, who are mostly satisfied if they get a crisp, bright picture, including the amount of subject they require.

It is worth while to turn our attention to special effects of lighting, by which many otherwise unattractive scenes are rendered beautiful. Perhaps the most striking effects are seen when the sun is directly in front of the camera, tipping all intervening objects with outlines of light. To be able to notice and appreciate the effect, we must shield our eyes from the direct rays of the sun, and it goes without saying we must protect the lens in the same way, or the result will probably be fog and flatness. Given, however, a good subject, and exercising care, our picture should be exceptionally attractive. Some of the most, to me, pleasing pictures I have seen were taken with this style of lighting, and I can honestly recommend it to any on the look-out for artistic effects. With this particular style of illumination, dust makes itself obnoxious as atmospheric haze, and in dry summer weather often forms an utter nuisance, not only with this but other styles of lighting, especially in the neighbourhood of much-frequented thoroughfares. The amount of dust raised by a rapidly driven vehicle will often stop photography for some little time. I have before now had to give up a subject for no other reason, as the frequent passing of vehicles did not allow the dust to subside sufficiently to get clear shadows.

Negatives taken during a shower, so long as the lens itself is protected from the rain, are often surprisingly clear, much more so than might have been anticipated. In showery weather the light is at its best; all the obstructive dust particles are washed out of the atmosphere, much to the advantage of the photographer. It is not advisable, in a general way, to make an exposure *directly* after a shower, as the beads of moisture on different surfaces reflect the light and produce spottiness. As soon, however, as this has dried off, things are in as good condition as they can be expected to be. This applies especially to roadside studies of flowers and foliage, mixed with stones and earth, which, being damp, harmonise in colour better than when quite dry; in limestone districts this is very observable. Water, than which there is nothing better to give effect to a picture, should be taken at such an angle that will avoid that blank, white look it sometimes has when taken from an improper standpoint, the camera being too high or too low, as the case may be. By all means get the reflections of surrounding objects in it, not cut out

so that there is some difficulty in telling the right way up of the picture, but sufficiently distinct to make good even lights and shadows, and suggest the rest. A slight undulation of the surface will give much more depth and limpidity to water than perfect quiet at any time, whereas a sharp gust of wind will entirely destroy the liquid effect, and make it look more like a chalk road than anything else I can think of.

In searching for views, it frequently happens that the most picturesque will be found along the course of rivers and in valleys rather than in the higher grounds. Of course, good pictures may be found in either, but the valley is more prolific in subject-matter than the hills, for land rising towards the distance helps somewhat to modify that dwarfing effect we find when working on level or from higher ground. Again, the time of day is of considerable importance in securing effect. Midday seldom produces such artistic pictures as earlier or later, especially in the height of summer, when lengthy shadows often help the composition most materially with variety of forms that are entirely absent with the more vertical lighting of a midday sun.

Too great stress cannot be put on the importance of suitable lighting; definition is quite secondary to it. A cleverly lighted picture will invariably give a favourable impression, even if the composition and definition leave much to be desired. It is the general effect of chiaroscuro that first attracts, and afterwards the detail. If, however, the light and shade are badly managed, the definition and form, however excellent, never satisfy, and the more the picture is looked at the more is the deficiency felt. It may not always be easy to say why a picture fails to please, but, nine cases out of ten, it is because of the bad management of the light. If the composition is inartistic, or if the definition leaves much to be desired, there is no difficulty in seeing it, and we know the cause of offence; but there is more subtlety about lighting, and one cannot always say off-hand the exact reason a photograph displeases us. I would therefore impress on all photographers to be especially careful in lighting their pictures, and time spent over this is seldom barren of result.

The foreground, being nearest the eye, merits very careful attention, and a thoroughly good, well-arranged foreground goes a long way to give character to the picture. It should never be plain and uninteresting if it is possible to prevent it. If the natural arrangement is deficient in form, extraneous objects can often be introduced to make up the deficiency. In doing this, incongruity must be avoided, and whatever is brought and placed must be in such position that it might naturally have assumed. If no care is taken in this respect, the evident make-up will undoubtedly spoil the effect, and instead of proving a help will be just the contrary. So long as a nice effective bit of light and shade is introduced, we shall have succeeded in gaining our ends, and turned our uninteresting patch into something that is grateful to the eye and helpful to the composition of the picture.

From the foregoing article it will be gathered that the writer wishes to emphasise the fact that one well-thought-out photograph is worth many taken hap-hazard; that a photographer should set out with some definite ideas as to the pictures he will endeavour to secure, and not make his exposures in an indiscriminate, happy-go-lucky sort of way, to only find out, on development, that if so-and-so had been a little different, which it might easily have been, it would have turned out a success instead of a failure; the result would be fewer exposures and more pictures.

EDWARD DUNMORE.

#### MERCIER'S IMPROVEMENTS IN THE PREPARATION OF ARGENTIFEROUS SENSITIVE SURFACES FOR PHOTOGRAPHIC PURPOSES.

M. MERCIER states that his invention relates to the preparation of argentiferous sensitive surfaces capable of bearing a longer exposure to the light than heretofore, such surfaces—whether under the form of plates, paper, or films, and whether utilised for positives or negatives—producing photographic images by the aid of suitable developing means. A further object of the invention is to obtain more vivid images than heretofore when the exposure has been inaccurate, and especially when it has lasted too long. The invention consists in adding to the emulsion of argentiferous salts one or more chemicals, which he classifies under the headings or groups, A and B, the latter comprising two subdivisions each.

"Group A comprises:—

"1. Antimonial salts mixed with an organic salt, such as a citrate or a tartrate. I use, preferably, tartar emetic, *i.e.*, tartrate of antimony and potash.

"2. Morphia, codein, their salts and derivatives. To utilise the substances belonging to this group A, I prepare a solution containing from 1 to 3 grammes of the substance selected per 100 grammes of water, and I immerse therein the sensitive surfaces or film for a period of about two minutes, after which the same is violently shaken in order to expel the excess of liquid, which would otherwise produce stains, and is finally allowed to dry. This treatment is preferably carried out before exposure. It may, however, also take place after exposure, but it must always precede the developing stage.

The developing means used should preferably contain hydroquinone mixed with sulphite and carbonate of soda, to which I add a small

quantity of an alkaline bromide, such as usually practised when the exposure has lasted too long.

"Group B comprises:—

"1. The active substances forming the base of alkaline developing means, such as hydroquinone, metol, ortol, amidol, pyrogallol acid, para-amidophenol, pyrocatechin, glycin, resorcin, and the like, to which may be added apomorphia, apocodein, and eserine or physostigmin; these substances being kept in their normal or unoxidised state by the addition of a small quantity of an acid, such as acetic acid, or of an alkaline sulphite.

"I am aware that several of the substances hereinbefore mentioned have already been used in addition to the argentiferous emulsion for photographic sensitive plates; but in such cases this addition had not for its object to aid in the development of the image when the exposure had not been very accurate, and when using a suitable developing means such as that having a hydroquinone base, and containing bromide, whilst the addition of such substances to the sensitive surfaces was effected without any acid or alkaline sulphite.

"In utilising the above substances, I may proceed as for those of group A, but it is preferable to use weaker solutions containing only about 10 centigrammes of one of these active substances and 1 to 2 grammes of acetic acid or 1 to 2 grammes of sulphite of soda per 100 grammes of water.

"The substances mentioned in the above paragraph in an oxidised state and in smaller doses. Such substances have not been used before in an oxidised state in which they are highly active and thus allow of a more prolonged exposure to the light. To obtain these substances in an oxidised state, they are merely dissolved in water with or without the addition of a few drops of an alkaline substance, such as ammonia or a concentrated solution of carbonate of soda, and the solution is exposed to the air until it is strongly coloured. Thus good results are obtained with amidol which is readily oxidised when using a solution containing 1 centigramme of this substance per 100 grammes of water and with which the sensitive plates are treated in the manner indicated for group A. Sensitive plates thus treated may give utilisable photographs even after an exposure to light one thousand times too prolonged, when the same are developed with the means hereunder mentioned.

"With reference to groups A and B, rapid developing means, such as those based on amidol or containing caustic alkalies, do not yield good results when the exposure to the light has lasted too long. The following formula is the best for developing purposes:—

Hydroquinone.....	10 grammes.
Sulphate of soda .....	60 "
Carbonate of soda .....	60 "
Bromide of potassium .....	5 "
Distilled water .....	9.8 to make up one litre.

"Instead of using—in the treatment hereinbefore set forth—sensitive plates, paper or films prepared beforehand, *i.e.*, such as found in commerce and of immersing them in the solution of the substances aforesaid, I may add the said substances to the argentiferous solution directly, *i.e.*, before spreading the same over a glass plate, a paper sheet or a film."

#### LEHMANN'S PLATE AND PRINT-WASHER.

THE invention consists in an apparatus which, when placed under a tap, allows a continuous flow of water over each plate separately, thereby removing and carrying off the hyposulphite of soda silver from the film of the plates or prints in a very quick manner, without any of the contaminated water coming again in contact with the plates or prints.

The apparatus is entirely constructed of zinc, and is composed of a tank, *a*, trays, *c*, and a receiver, *f*.

The tank may be narrow at one side, but the other side must be a little broader than the sides of the plates for which it is intended; the height varies according to the number of plates to be washed at a time.

In the broad side of the tank are horizontal lines, or groups, of small holes, the position of which is shown in fig. 2 by an arrow, and a little below each line of perforations is fixed one end of a tray, *c*, for holding the plates in a right angle to the tank, but preferably with a slight downward inclination.

At the opposite end of each tray one or more spaces, *d*, are cut out of the rim, with the double object of allowing the plate to be lifted, and also as an outlet for the water from the tray.

The trays are connected and supported at the sides by upright stays, *e*, and the apparatus is placed or fixed in a large tray, *f*, which serves as a receiver of the waste water, and has an outlet, *g*.

A strip of zinc, *b*, is attached on one side to the tank a little above each line of perforations, while the other side reaches down obliquely to within  $\frac{1}{2}$  inch from the bottom of each tray; see fig. 2.

After developing and fixing photographic plates, the latter are laid face upwards in the trays of the apparatus, which is then placed under a tap, so that water can pour into the tank. The fine jets of water issuing from the perforations are broken by the strips, *b*, and form into homogeneous sheets which flow over the plates and through the openings, *d*, into the receiver, *f*, whence the collected water is carried away through the outlet,

*g*. The water supply from the tap is regulated so that the tank remains always full to the top.

The apparatus is chiefly intended for washing negatives or other plates, but it may also be adapted for photographic paper prints.

For this purpose carriers (fig. 8), made of perforated zinc plates, bordered on both sides, but not at the ends, by narrow strips of zinc, *h*, of at least  $\frac{1}{2}$  inch depth, are used. These carriers must fit loosely in the trays, so that only the borders, *h*, rest on the bottom. The prints, *i*, are laid face upwards on the carriers, and fastened at the top by means of small clamps, *k*, as shown in fig. 3, or by any other suitable contrivance. When placed in the trays the photographs get washed on both sides of the paper by the water flowing underneath and above them.

The following are suitable dimensions for an amateur apparatus for washing six half-plate size negatives:—

Size of tank,  $10 \times 5 \times 2$  inches; size of trays,  $5 \times 7\frac{1}{2}$  inches, with rims inch high, and two outlets of  $\frac{1}{2}$  inch width. The trays are attached to the tank, with the rim close below the row of perforations, and the breakwater strips  $\frac{1}{2}$  inch above the holes, and reaching obliquely down to about  $\frac{1}{2}$  inch from the bottom of the trays.

The receiver, *f*, can be 12 inches long, with a rim  $1\frac{1}{2}$  inches high.

The perforated lines are 1 inch apart, commencing 3 inches from the

provided at their circumference with soft indiarubber rings, press upon the passing bands, *g*, in order to reduce their rate of motion.

Fig 2

Plate, *h*, extending in its longitudinal direction up to the pulleys, *f, f* (although not shown, for the sake of clearness in the drawings), is provided, directly underneath the mouth of the coating reservoir, *p*, with a transverse slot through which the waste emulsion drains away into the

Fig 1

Fig 2

Fig 3

op; the holes are of the size of an ordinary pin's head, and number 25 in each of the three upper rows, 23 in the fourth, 20 in the fifth, and 17 in the sixth or lowest row.

#### THILMANY'S PAPER-COATING MACHINE.

Two endless bands, *g*, of about half an inch in width, and provided with small pins, are arranged so as to run over two pairs of pulleys, *ee* and *ff*, the latter pair being adjustable in the longitudinal direction of the table. Thus, various bands of different length may be employed,

trough or duct, *o*, which extends across the whole width of the paper to be coated. Corresponding to the space required for the free motion of the bands, *g*, the plate, *h*, is provided at its sides with longitudinal grooves in which the said bands are to run over their respective pulleys.

The disadvantageous downward bending of the paper sheets is completely avoided in this improved apparatus, since the paper does not leave its support (plate, *h*), and is raised and guided by pins at the two longitudinal sides of the table when the coating substance is poured on it.

Behind the pulleys, *ff*, the paper sheet, being now coated with emulsion, is removed from the pins by a taking-off plate, *r*, and may be stored in the ordinary manner.

This apparatus is set in motion either by hand, as shown in the drawings (fig. 2), by means of a crank lever, *s*, mounted on one of the shafts of the said pulleys, or it may be actuated by mechanism and motive power.

Fig 1

running over the pulleys according to requirement, and at the same time the bands are easily kept taut.

The paper to be coated with emulsion is laid upon plate, *h*, and conveyed up to the pulley, *ee*, at the top of which corresponding rollers, *i*,

#### HONOURS FOR SIR G. G. STOKES.

SIR GEORGE GABRIEL STOKES, upon whom the University of Cambridge is bestowing many honours this week, was born in 1819 at Skeen, co. Sligo, and was educated at a Dublin school, at the Bristol College, and at Pembroke College, Cambridge. He was Senior Wrangler in 1841, when he was appointed to a fellowship, and in 1849 he was appointed to the Lucasian Professorship of Mathematics at the University. He was elected a Fellow of the Royal Society in 1852, and in the same year was awarded the Rumford medal in recognition of his discovery in the change in the refrangibility of light. From 1854 to 1860 he was lecturer at the Royal School of Mines, when he resigned, and so long ago as 1869 he was President of the British Association when it met at Exeter. For some years Sir George Stokes acted as one of the secretaries of the Royal Society, and in 1885, on Professor Huxley's retirement, he was elected President, and was succeeded by Lord Kelvin in 1890. From 1887 to 1892 he represented the University of Cambridge in Parliament, and was

created a baronet of the United Kingdom in 1889. He is an Honorary Fellow of many of the foreign academies, and all our leading universities have conferred upon him the highest honours they can bestow in the way of honorary degrees. His contributions to the transactions of the learned societies have been many and varied, and the Burnett lectures on "Light," delivered at Aberdeen, and afterwards published, would alone have won him a wide reputation, while his discourses on "Natural Theology," delivered as Gifford Lectures at Edinburgh, bear testimony to his wide range and his high attainments in other directions than those of pure mathematics or experimental science. Sir George has been a member of the Royal Photographic Society since 1856.

## Our Editorial Table.

### THE ZENITH CAMERA.

Kodak, Limited, 43, Clerkenwell-road, S.E.

THE No. 3 and No. 4 Zeniths are constructed for use with glass plates in double plate-holders, and are also adapted for exposures on rollable daylight film in an Eastman's cartridge roll-holder, the latter being readily interchangeable with the plate-holders. In addition to a carefully graduated scale, the Zeniths are provided with ground-glass focussing screen upon which each separate exposure, whether on film or plates, may be focussed if desired. There are sockets for tripod screws, view-finders for vertical and horizontal pictures, &c.

The No. 3 Zenith, for  $4\frac{1}{2} \times 3\frac{1}{2}$  plates, measures  $4\frac{1}{2} \times 5\frac{1}{2} \times 9\frac{1}{2}$  inches. The weight is thirty ounces. The No. 4 Zenith, for  $5 \times 4$  plates, measures  $5\frac{1}{2} \times 6\frac{1}{2} \times 11$  inches, and the weight is thirty-three ounces. The Zenith cameras are fitted with lenses giving excellent definition, and have sets of three stops. The shutters are of the rotary type, and are everset. For snap-shots the exposure lever is simply pushed alternately to the left or the right, as the case may be. Time exposures are obtained by the adjustment of a simple catch, so that it engages with a projection on the shutter.

### AMERICAN PORTRAIT STUDIES.

Collected and arranged by CHARLES HETHERINGTON.

133 pages, containing 470 portrait and group studies. Price 12s. 6d.

London: The Photogram, Limited, 6, Farringdon-avenue, E.C.

WHEN drawing attention to our American contemporaries and their annuals we have often dwelt upon the characteristic excellences of Transatlantic portraiture, which perhaps, save in respect of the work of the leading British photographers, has a *vim* and style not seen in the productions of the rank and file here at home. The volume before us enables us, by the courtesy of Mr. Snowden Ward, to see at a glance reproductions of a large and representative collection of American portraiture, to which over ninety photographers make contributions. The work is also decoratively illustrated, and there are some articles on subjects of interest to professionals. The greatest praise we can bestow on the volume is this, that it is worth acquisition by British professionals in order that they may gain a direct idea of the characteristic excellences and features of posing, lighting, and treatment which American portrait and group work undoubtedly possesses. It is really a splendid object-lesson in American professional work.

*How to Make Snap-shots* (price 1d.) is the title of a little guide to photography issued by Mr. W. Tylar, 41, High-street, Aston, Birmingham. It is designed for the use of beginners, no matter what camera they may use, and the information it contains well fulfils that purpose.

### CATALOGUES RECEIVED.

MESSES. ADAMS & CO., of 26, Charing Cross-road, W.C., send us a beautifully produced pamphlet describing and illustrating the Adams De Luxe cameras, and giving many fine reproductions of negatives taken in those superb instruments. The list, which is a most artistic production, is sent to applicants on receipt of ninepence.

The Monroe Camera Company, Sutton House, 2, Old-street, E.C.

THE little forty-six page catalogue of the Monroe Camera Company is plentifully illustrated. It gives prominence to the varied series of hand cameras which are the specialities of the Company, and lists general photographic apparatus and sundries. Those photographers who appreciate hand cameras, on what may be termed the American model, should send for a copy of this catalogue.

The London Stereoscopic and Photographic Company, 54, Cheapside, E.C.

THE new "City" catalogue of the London Stereoscopic Company is filled with particulars of a large assortment of apparatus suitable for amateur photographers and others. The "City" new roller blind shutter, time and instantaneous, with speed indicator, is one of the specialities of the Company, who are putting a new brand of plates on the market also termed the "City." At the Company's handsome premises in Cheapside one is always assured of obtaining the very latest introductions to the photographic market, indeed, the apparatus department in the experienced hands of Mr. E. Miles, is one of the most stylish and skilfully conducted that we know of.

W. F. Slater, 5, First Parade, High-road, Lee, S.E.

In this net wholesale list of frames and mounts, Mr. Slater gives prices of "club" frames; solid oak with gilt or gold slips; carved solid oak; exhibition frames (the "Royal" and the "Salon"); cut out mounts; plush mounts; sundries, &c. It is a list which photographers should always have at hand for reference, for Mr. Slater's work is uniformly good and tasteful and his prices are low.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, June 7. "The Joly Process," by Mr. J. W. Mason.

ON Wednesday, May 31, Mr. H. Snowden Ward lectured at the London Chamber of Commerce on "The Philadelphia Commercial Museum."

ARRANGEMENTS are in progress by the British Astronomical Association for the organization of two expeditions to observe the total solar eclipse of May 28, 1900—the one to Portugal, Spain, and Algiers; the other to the United States.

BANK-NOTE FORGERIES IN HUNGARY.—A lithographer named Hochrein and a mechanic named Goepl have been arrested at Fünfkirchen, Hungary, for forging ten-gulden notes. The notes were produced by a photographic process, and large numbers of them were put into circulation.

IN the possession of the Hon. Treasurer of the Birmingham Liberal Club (Mr. J. Rowlands) is a curious photograph of special interest. The photographer took a "snap-shot" of Tenby Church and steeple, and on developing the negative was surprised to find the picture disfigured at the top by the reversed figure of a vessel dressed with bunting. The key to the puzzle was discovered the next morning in the report of the launching of a vessel in Pembroke Dock, seven miles away. The plate "caught" a mirage of the launch.

A PARTIAL eclipse of the sun, which will be visible at Greenwich and throughout Northern Europe and Northern Asia, takes place on June 7. At places where the greatest eclipses will be visible somewhat more than half the sun's diameter will be obscured, although in our own country only about one-fourth or one-fifth of the diameter will be obscured. At Greenwich (and approximately throughout the British Isles) the first contact is  $42^\circ$  from N. towards W., and last contact  $29^\circ$  from N. towards E. At Greenwich the eclipse will last an hour and ten minutes, the maximum being reached at 17 h. 17 m. Greenwich mean time.

A DEMONSTRATION of various processes with tabloid chemicals was given at the Polytechnic Society's meeting on May 24 by F. Wilson. These very convenient, portable, and reliable photographic chemicals were specially recommended by the lecturer for travellers, beginners, occasional workers, and any one to whom the compounding of formulas or multiplicity of bottles and solutions is objectionable. The simplicity of the operations of developing plates with pyro and accelerator, reducing with ammonium persulphate, developing bromide paper with metol, &c., and toning P.O.P. with gold and sodium formate were successfully demonstrated, as in each case the tabloids acted perfectly in every respect.

TELEGRAPHING pictures seems to have become a common practice with some of the American papers. Recently five of the chief newspapers in the New World, in different States, were placed on the same circuit, and, at a given signal, certain pictures were sent. These have been published, and are fairly clear and graphic representations. The machine was invented by Mr. E. A. Hummel, and provides for the making of a drawing on a sheet of tinfoil wrapped round a cylinder somewhat similar to the wax cylinder of a phonograph. When the current is turned on, the cylinder revolves and a needle pricks the foil and touches the outlines of the picture. At the other end of the wire is a similar machine working in harmony, only instead of a sheet of tinfoil a piece of carbon copying paper is placed between two sheets of paper. Every movement of the point in New York is reproduced, causing a corresponding movement at the other end, and giving a faithful copy of the picture. It is claimed that the picture of an event taking place in Chicago at ten o'clock could be absolutely reproduced in New York by eleven.

**THE LATE MR. JOSHUA BILLCLIFF.**—The death, at the age of seventy-eight, of Mr. Joshua Billcliff occurred on May 5 in Coupland-street, Chorlton-upon-Medlock. He was in many respects a notable man, and was best known as a maker of cameras. He was a pioneer in the work, having established the business thirty-nine years ago. According to the *Manchester Evening News*, he was the original maker of the widely known Thornton-Pickard camera and M'Kellen's double-pinpoint camera—which in 1884 gained the only medal until then awarded by the Photographic Society of Great Britain—was turned out from Mr. Billcliff's works in Richmond-street, Chorlton-upon-Medlock. Born near Penistone, and by trade a joiner, he settled in Manchester in 1854, selecting Stretford-road, Hulme, for the scene of his labours, carrying on a shopkeeping business in the front, and utilising the yard for his trade. Photography was making great strides at the time, and, possessing strong mechanical tastes, he drifted into the line in which he was destined to become prominent. Almost the very first hand camera made, and which was patented by Mr. Warwick Brookes, was made in Richmond-street, as well as several of the immense cameras used in the photography of the moon.

## Patent News.

THE following applications for Patents were made between May 15 and May 20, 1899:—

**SHUTTERS.**—No. 10,636. "Improvements in Photographic Roller-blind Shutters." J. E. THORNTON.

**BACKING APPARATUS.**—No. 10,564. "An Improvement in an Apparatus for Backing Plates, Films, or other Tissue, for Photographic Purposes." J. SKILBECK and W. J. WARREN.

**STANDS.**—No. 10,698. "An Improved Support for Photographic Cameras or other Instruments requiring a Level Base or Stand." H. P. HANSEN.

**CAMERAS.**—No. 10,318. "Improvements in or connected with Photographic Cameras." A. J. B. LÉGE and W. H. ENGLAND.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 25.—Mr. A. L. Henderson in the chair.

Mr. HERBERT S. STARNES read a paper on

IMPORTANT PHOTOGRAPHIC PROBLEMS THAT REQUIRE INVESTIGATION.  
[See p. 342.]

Mr. R. BECKETT, in the discussion which followed, said that the paper furnished an explanation of a fact that many had noticed, viz., that the developed image was more permanent than the printed-out image, owing to the developed image containing more silver than the printed out, in which latter the author had shown how little silver was finally left. He was inclined to ask "What is art?" when the question arose as to whether a photograph could or could not be art. He thought that the prevailing loudness of tone and lack of brilliancy was altogether contrary to nature, and to be discouraged.

Mr. BARKER was of opinion that the sub-bromide theory of the formation of the latent image was a possible one, because he did not see how it could explain reversal. As regards silver prints and toning, he had always held that a silver print severely left alone was more permanent than if it had been toned with gold, and this he could support with proofs. He had silver prints, made by Warwick Brookes probably twenty years ago, in the form of negatives. They were printed to a red colour, not toned, were on albumen paper, and some were waxed, but all were still as perfect as ever they were. He wished to know why photographers should imitate artists; rather let artists imitate photography. In history artists filled a big place, but photography had gone one better. It was a later advancement, immensely superior, and for that reason let artists, he said, imitate photography, a thing they cannot do.

Mr. A. MACKIE remarked that Mr. John Spiller had that day shown him a number of interesting photographs. Amongst others hanging upon the walls were pictures medalled in 1869 and 1870, and measuring about 30×22, in which there was absolutely no change to the eye; they were beautiful in colour and admirable specimens of photography. There were also some portraits, taken at Woolwich Arsenal, of Garibaldi and others, but no change was apparent, and all were albumen prints.

The CHAIRMAN, in speaking of the sensitising of albumen paper, referred to the formation of what was called albuminate of silver, suggesting that a similar combination took place in the case of gelatine emulsions. He was in agreement with the opinion that prints not toned with gold were more permanent. It might perhaps be explained in this way: the untuned print was of a soxy colour, and, if this colour was altered in the toning bath, it was improbable that all the silver of the image was covered with gold. The result was that the print was composed of two substances, of which one might alter in colour in the course of time, and make it appear that the print was lacking in permanence. On the other hand, if the print were not toned, any change would be a general one and less noticeable. For this reason an untuned print was less liable to change in colour, and this led him to say that, however much the colour of the print may change, the silver, which was not volatile, was still there. He asked if any one could account for a change of colour in some gold-toned prints, which in 1864, when made, were of a fine purple colour, but now, by simple exposure to air and moderate light, had become as if not toned at all. He was of opinion that the substance of the paper used for sensitising was largely responsible for the permanence of print, and that the paper of the present time was not so good as that of older times. The paper itself seemed to change colour.

Mr. MACKIE did not think that the manufacture of such paper as Rives could have altered. Alluding again to the colour of prints, he related that he had a number of matt gelatino-chloride paper prints, made some years ago and toned with platinum. Originally nearly red in tone, they had become almost black. They were toned before fixing, and it was curious to note how the red pigment used for spotting now stood out from the rest of the print.

Mr. PHILIP EVERITT said that, as regards the question of the latent image, the experiments of Kogelmann had an important bearing. He took a number of plates and gave them varying exposures, increasing from a minimum to a maximum, and then right away through to reversal. Some of the plates were then fixed carefully and thoroughly washed. He then developed them with a physical developer and obtained images. Without suggesting the nature of the substance forming the latent image, it did seem curious that the plates should, after fixing, be amenable to development, and he thought it was a great difficulty in the way of the sub-bromide theory. Kogelmann's idea was that the latent image, if not silver, was some form of silver very nearly akin to metallic silver. Looking a little further, the theory of reversal seemed not very difficult of explanation. In the ordinary or normal exposure the mere skin of the particle of bromide was exposed, the inner portions of what may be termed a cube being unaffected, some time being required to penetrate to its full extent. Such an exposed film, fixed, would be deprived of the inner mass of bromide, leaving an outer shell of altered bromide. In this way one would have a plate in the gelatine of which would be a series of cavities, which, by physical development, are afterwards filled up or have silver deposited upon them. Increase the exposure to the point of reversal. The whole of the silver bromide is affected in such a manner that it becomes no longer amenable to development. Does not this point to the fact that, in order to develop an image on a bromide plate, one must have the exposed bromide, plus unaltered bromide, the developer being the connecting link? In reversal we should have no unchanged bromide, which the theory requires for the development of an image, hence no development would take place. Kogelmann used pure bromide plates for the experiments.

Mr. J. E. HODD asked, however, whether it was not a fact that, with two plates to which an exposure had been given which by ordinary development was found to have produced reversal, by altering the mode of development for the second plate the reversal effects could be counteracted?

The CHAIRMAN said he had done so by using a proportionately large quantity of developer—eight to ten ounces for a quarter-plate—and continually changing the same, flooding the plate, pouring off, and applying fresh. He ascribed it to the enormous amount of bromine liberated from the over exposed part that made it appear reversed, the bromine acting as a strong restrainer. The continual change of solution he resorted to carried off this bromine, and enabled him to secure a normal effect in a plate which would otherwise have appeared reversed.

The discussion was long and went much into detail.

Mr. STARNES replied in due course, and emphasised his views, and was accorded a hearty vote of thanks.

### PHOTOGRAPHIC CLUB.

MAY 24.—Mr. J. R. Gotz in the chair.

Mr. HENRY TROTH, of the United States, was introduced to the members, and passed round some photographs of flowers—a branch of photography in which he has achieved considerable success and notoriety in America and here in England. Mr. Troth explained that his photographs were mostly taken for their botanical value, with as much artistic quality as could be included while preserving the original purpose. For yellows he employed as a rule a fast isochromatic plate, and for the blues a slow isochromatic plate without a colour screen. He preferred to adopt this latter course, as there was more light available for focussing if the colour screen were dispensed with. When a yellow screen was employed, Mr. Troth used Bausch & Lomb's ray filter or bichromate cell. The examples were, with few exceptions, taken with a vertical camera. In some cases the flowers were simply placed upon black velvet, in others upon glass supported above the ground, with a suitable background underneath. Daylight was employed throughout, and cold-bath platinum was the printing process selected.

Mr. J. NESBIT showed a photograph of his friend the late Alfred Bryan, artist to *Moonshine*, *Entr'acte*, and other papers, and pointed out that copies were being retailed by a certain photographer of Holborn, although he (Mr. Nesbit) claimed the authorship of the photograph.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

### COLOUR FACTS AND FALLACIES.

To the EDITORS.

GENTLEMEN,—In consequence of your persistent and determined attempts to misrepresent everything connected with myself and my work, I wish to add one or two facts. It is a fact that in 1869 Du Haaron introduced a method using a lined screen. It is a fact that in 1876 Du Haaron introduced the three-colour method, with colour glasses and an arrangement for viewing the results. It is a fact that you have not described either Mr. Ives's or Dr. Joly's processes as having been tried and abandoned as useless thirty years ago, although they were introduced at that time. It is a fact that you have constantly ignored my statement, made in 1895, that I could obtain photographs in colour by three different methods, and, still ignoring that fact and statement, you endeavour to represent me as a liar, and have associated my name with whatever you can that is degrading. It is a fact that your hostility to me dates from your receipt of a letter from my solicitor.—I am, yours, &c.,

JOHN WALLACE BENNETTO.

The Studio, Newquay, Cornwall, May 30, 1899.

[And, above all, it is a fact that Mr. Bennetto has not yet solved the problem of photography in natural colours without the use of "dyes, stains, or pigments," as he claimed to have done in 1896.—EDS.]

### Re SPOTS ON PRINTS.

To the EDITORS.

GENTLEMEN,—The correspondence on the above subject reminds me of an incident which occurred in my practice which indelibly fixed one cause of minute black spots on prints in my memory.

I was called away one morning last fall from printing to photograph a machine in a neighbouring foundry and machine shops. When I had taken the negative I resumed printing P.O.P. When I came to tone in the evening I found all my prints literally ruined with minute spots.

I attributed it to the minute specks of iron dust that had attached themselves to my clothes while in the foundry, and subsequently transferred themselves to the surface of the prints while examining them in printing.

I now, however, use a preliminary bath of salt water when immersing dry prints, and find spots conspicuous for their absence.

I may say I consulted the Britannia Company on this point, and they assure me it will not harm the prints, and it certainly prevents iron spots.—I am, yours, &c.,

OTHELLO.

To the EDITORS.

GENTLEMEN,—In your last issue Mr. W. Palmer refers to above as being caused by the iron bearings of his roller squeegee, and I think he is wise in discarding these abominations. For many years I have used a round piece of box wood, 6×1½ inches—like a small rolling-pin—for rubbing down with. It can be held firmly in the hand, and much or little pressure easily brought to bear on the print. I found above in use in the establishment of the late Vernon Heath, and a very useful tool it has always proved to me.—I am, yours, &c.,

HERBERT W. BIBBS.

68, Princes-street, Edinburgh.

### AN ALLEGED PIRACY.

To the EDITORS.

GENTLEMEN,—I would like to draw your attention to a glaring piece of piracy on the part of a fellow photographer. I think it puts the cheek of the free-portrait and colour photography cranks to shame. What I refer to is a photograph of Colonel McDonald, the Sudan hero, which appeared in a number of magazines and newspapers, and bears the name of a

photographer who did not take the original picture, but merely copied it. This would be all right had the said individual permission from the original photographer to do so, but he had not. I think a case of this sort deserves showing up. What do you say, Mr. Editor?—I am, yours, &c.,

"DINGWALL."

P.S.—The free-portrait swindle penetrated this far, and a number of people indulged, and are now sadder and wiser. I prevented a few from being "done," and secured their orders.

[If the photograph referred to is copyright, the copier can be proceeded against for infringement. So much for the legal aspect of the case; the morality is obvious.—Ed.]

### A SOCIETY FOR PHOTOGRAPHIC PRINTERS.

To the EDITORS.

GENTLEMEN,—Mr. Randall says, "Mr. Willatt is mistaken in supposing that I view the question of trade unionism for photographic assistants through organizations already formed." Now, sirs, I leave the question entirely in the hands of readers of this JOURNAL to decide. All I can say is that, so far as this present correspondence has gone, this is exactly what he has done. Mr. Randall gives references to this JOURNAL for 1897, 1896, and even 1895, to try and show my statement to be incorrect. With these references I am not in the least concerned; I am only concerned with Mr. Randall's remarks in the present correspondence. What he has said in 1895 I am not going to discuss; I know what he has said in 1899.

Again: photographic assistants do not seem at all inclined to join the Shop Assistants' National Union; but, if Mr. Randall chooses to fully explain the working details of the same, and what amount of restriction would be put upon photographic assistants, I think he might induce some to join it, provided its present aspect were not too restrictive. I do not say he (Mr. Randall) has not explained it in past years, but what would be necessary would be a constant reiteration of the policy and advantages of such a union. In the mean time, my idea is to start something to improve and assist the photographic printers, not to place them "right off the reel," as Mr. Randall says, on a par with engineers or compositors.

I have tried to be plain and precise; I have never once hinted at a full-blown union on a level with engineers, compositors, plumbers, joiners, bricklayers, &c. It is rather Mr. Randall who has put the question in that light by asserting that, unless photographic assistants joined a union (one already in existence, of course), they could reap no advantages. Let any of your readers peruse his replies, and judge. In conclusion, if photographic assistants (printers or otherwise) do not see any necessity for such improvement, neither Mr. Randall nor any one else can help in any way.—I am, yours, &c.,

F. G. WILLATT.

101A, Fulham Palace-road, Hammersmith, London, W.,

May 25, 1899.

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS AND PAINTING REGISTERED:—

W. Blake, 38 and 40, High-street, Bedford.—Photograph of the late Robert Barry Stafford, Esq., J.P.

A. England, Triangle Studio, New Barnet.—Photograph of dog with kitten and parrot on its back. Photograph of cat and parrot.

J. A. Martin, Adelaide-street, Fleetwood.—Painting of Fleetwood lifeboat to the rescue.

GLOSS.—Sorry to say we can give you no more information than that contained in the advertisement.

T. A. G. WEST.—We do not think you have a legal remedy. The word "permanency" is vague and indefinite, and does not convey that you were engaged for a fixed period.

VARNISH.—S. BARKER. The sample sent is not mastic at all, but is dammar. This resin is much cheaper than mastic, and, if you were supplied with it at the price of the latter, you have been defrauded or a mistake has been made.

**JAMES HENDERSON.**—We know of no such book; but Gauthier-Villars, 55, Quai des Grands Augustins, Paris, publish several French books on photography which might give you the desired information. Write them for a list.

**BLACKENING STOPS OF LENSES.**—A. G. says: "The stops of my lenses, through so much use, are bright. Could you kindly inform me how I may make them a dull black?"—See answer to W. C. Johns, and refer to page 972 of the ALMANAC.

**NORTH LIGHT.**—UNCERTAIN says: "Given a wall running due east and west, on which side is the so-called 'north light' supposed to fall, that facing north or that facing south?"—That facing the north, of course; the other would be the south light.

**A. F. F.**—1. The aperture need not be absolutely circular, but the nearer it approaches to it the better. 2. The scratches will not prove a drawback in practice, but they should not be there. 3. Both are excellent for the purpose; we do not make distinctions or recommendations.

**WATER SUPPLY.**—S. AND C. If the Water Company will not supply water to the private house you have taken to do your printing at, except by meter, you will have to take it on those terms. The Company are quite within their rights, as you require the water for trade purposes.

**AMYL-ACETATE.**—CELLULOID writes: "Can you please tell me where I can get some amyl-acetate? I have tried all the chemists' shops here, and none of them keep it. They seem to know nothing of the stuff. One said there was no such thing."—Amyl-acetate is rarely kept by ordinary druggists. You will be able to get it from houses such as Hopkins & Williams, Cross-street, Hatton Garden.

**INDIARUBBER SOLUTION.**—B. L. E. says: "Please tell me how to make a clear solution of indiarubber for pouring on plates," &c.—Simply dissolve pure indiarubber in benzole. The best kinds to use are masticated rubber or Para-washed sheet. You will find it more convenient to purchase the solution as sold at the indiarubber warehouses, and thin that to the consistency desired with benzole.

**CHANGING ARRANGEMENT.**—G. F. T. says: "I am wishing to fit a changing arrangement in a camera I am making. I want it to hold twelve or more plates. Can you give me instructions to make this?"—Several very convenient arrangements are now in the market; better see some of these. Many forms will be found described in the back volumes of the JOURNAL, but space is too limited in this column to repeat them.

**ACETYLENE.**—ACETYLENE "would like to know if a studio fitted with acetylene gas would do as good as daylight? Would I be able to obtain variety and softness in lighting? Is a book published on the subject?"—No book is published on the subject. Good portraits can be taken, with skill, by the acetylene light, and with a great variety in effects; but to say that a studio lighted by acetylene is as good as a daylight studio would be saying a great deal too much.

**BLACKENING BRASSWORK.**—W. C. JOHNS says: "1. I want to blacken some exterior brasswork of a hand camera, and in this year's ALMANAC, p. 972, a chemical stain is given. Will you kindly inform me if this is a suitable medium; also what proportions should I use? 2. Would black lead be necessary to finish the parts after staining? If so, how should this be done?"—Yes. About a hundred grains of each salt in two separate ounces of water, then mix the two solutions together. 2. Not necessary.

**COLLOTYPE.**—OTHELLO says: "Will you tell me: 1. What is the proportion of treacle and glue in making rollers for colotype? 2. What is the varnish for thinning colotype inks composed of?"—1. No very definite proportions can be given, as something depends upon the character of the glue used. There is glue and glue. In practice you will find it better to purchase the composition as made specially for colotype rollers. It may be had from such houses as Penrose's or Winston's. You will then ensure having the right thing. 2. Middle or thin litho varnish.

**USING PORTRAIT LENS FOR LANDSCAPES.**—S. CLARK says: "I have often used the back lens of my rapid rectilinear (with the front one removed) for landscapes, and have got good results. I have recently bought a portrait lens, and, on trying the back lens in the same way, I cannot get a sharp picture, even with a small stop. Cannot the lenses of a portrait combination be used as single lenses, as with the rapid rectilinear? I am told they can be."—It is the front lens only that can be used as a single lens. It should be screwed into the place of the back combination, with its convex side towards the focussing screen.

**CHICAGO.**—It amounts to this: One half of the stereoscopic picture is printed in red, the other in blue. Obviously, being dissimilar photographs, they cannot superimpose exactly; hence the lack of registration. The object of the coloured spectacles is to enable each eye to see only one of the two pictures, thus fulfilling stereoscopic requirements—the red cut out the blue and the blue the red—and so the dissimilar views are presented to the retina. The colours are very probably chosen much at hap-hazard; hence the colour of the stereo image. The extreme relief is probably due to the great distance of separation between the taking lenses.

**BICHLORIDE OF PLATINUM.**—PLATINUM says: "Amongst some job lots I recently bought, I find four fifteen-grain tubes of bichloride of platinum, and about half an ounce of platinum salts sent out by the Platinotype Company for their cold-bath paper some years ago. Can you inform me whether I can make use of above for the platinum-toning bath for C.C. paper in its present state; if not, for what purpose it is useful for and probable value of same?"—We should advise you to try the experiment, although we doubt if it will answer. The price quoted, retail, for fifteen-grain tubes of bichloride of platinum is about one-and-sixpence or one-and-ninepence a tube.

**COPYRIGHT.**—B. E. E. If you were paid for taking the portrait, you have no copyright in it. The fact that the sitter has since died does not entitle you to any copyright in the portrait. The family are quite right in defying you and your threatened proceedings, although you have registered the copyright. It was not yours to register.

**URANIUM INTENSIFICATION.**—COLONEL GUBBINS says: "Some time ago I bought a bottle of the Cresco-Filma Company's uranium intensifier, and used it. The result was, negatives spoiled by a multitude of spots (I enclose a print from one). I was told that I had not soaked the negative long enough, so I tried soaking for twenty-four hours, and enclose the negative, which I don't want returned. Although the negatives were not very old, I tried a bath of dilute citric acid (lime juice) with similar results. Is the fault with me or the intensifier? If the former, where is my mistake?"—As we do not know the precise composition of the intensifier, we cannot say. We should advise you to send an example to the makers, who will, doubtless, tell you where the fault lays.

**COPYRIGHT.**—COPYRIGHT says: "1. Will you kindly inform me how to act in this case? Two years ago I asked a certain friend to give me a sitting, as he was going abroad. He did so, and I presented him with two prints, and then he wished me to give him the negatives as well. Of course I refused, and now I find his friends have had the prints copied by some one else, and have enlargements as well as prints the same size. If I copyright the negatives now, could I compel them to give up these various prints, or could I claim compensation? 1. Is it 1s. 6d. and three prints of each that one must send to you for registration or more?"—In reply: 1. By registering the photographs you could proceed, but we much doubt if you could recover penalties. Certainly you could not compel the return of the prints in question. 2. One-and-seventeen and three prints.

**FORMATE TONING.**—H. C. says: "I have been trying formate of soda for toning, and find that merely substituting formate for sulphocyanide ammonium causes the toning to be utterly beyond control, both for P.O.P. and collodio-chloride, but especially the latter. Can you, through your Correspondence column, give me a formula, or at least tell me by what means the bath can be brought under control? When I say substituting formate for sulphocyanide, I mean, of course, using the same proportion—80 grammes to 2 grammes of chloride of gold. The prints are terribly washed out in appearance when finished."—Here is Mr. Henderson's formula for the formate of soda toning bath: 20 grains of the formate to from 1 to 2 grains of gold in 10 ounces of water. The solution should be made slightly alkaline with carbonate of soda. Probably the bath was used too strong.

**SODA DEVELOPMENT, &c.**—ABBEY says: "If, instead of making up my developing solutions, I keep my pyro soda dry, (1) is it necessary that I use bromide of potassium and metabisulphite of potash along with my pyro? 2. In the soda ought I to use equal quantities of soda sulphite and soda carbonate, or soda carbonate alone? 3. What weight of pyro ought I to add to one and a half ounces of water previous to mixing it with one and a half ounces of soda for normal exposure? 4. I suppose it is better to have soda made up in solution rather than weigh it out when required for development? 5. What style, or styles, is best for retouching or modelling the face in a portrait negative?"—In reply to 1, 2, and 3: Our correspondent does not state the strength of the soda solutions he uses. Several pyro-soda formulae are given in the ALMANAC. From any of these he will be able to calculate the proportion of dry pyro to use for whatever strength of soda solution he employs. Dry pyro is not often used with soda. 4. Yes. 5. Hard-muth's leads. Nos. 3 and 4 grades are what is very generally used.

**TRANSFERRED FILMS.**—FILMS says: "I am obliged for your kind reply to my query of last week re combination printing. The bath recommended in the article named answers perfectly, the film peeling off the plate without any trouble after only a few minutes' immersion. I have been experimenting with a few paper negatives, but find that, although there is no difficulty in stripping the film, small pieces of the paper support adhere to it, making it useless. I have been using the paper rolls for stereoscopic negatives, but find the grain rather pronounced for this class of work. If the films could be transferred satisfactorily to glass, they would be perfect, the price being so low and their bulk and weight so small. Can you suggest any means of doing so? Is there any way of dissolving the paper without affecting the film, or of clearing the adhering paper from the back before transferring to the glass?"—We know of no way of successfully stripping the film from ordinary paper, but we believe a special stripping film will shortly be on the market. The Novitas paper, however, might answer our correspondent's purpose.

**PLATINUM TONING.**—F. LEMMON says: "I enclose you a rough copy of a matt collodion toned with platinum, and should esteem it a great favour if you would tell me the cause of its being yellow in the half-tone and the remedy for this. I may say I am generally toning a lot of these every week, and most of them turn out as if over-toned, viz., yellowish round the vignetting. I wash the prints first in several changes of water, and then tone in the following bath, slightly warm: 1 teaspoonful of powdered borax, 20 ounces of water, and 2 grains of gold to every forty cabinets. I then wash again, not so much as first time, and tone in the following: 8 drachms of phosphoric acid in 20 ounces of water; of this I take 3 ounces and add 1 drachm of solution of chloride of platinum, made, viz., 1 tube to 2½ ounces of water and 15 drops of hydrochloric acid (this quantity tones fourteen cabinets); then wash again and fix in hypo slightly acid."—The prints appear to be somewhat over-toned and as if the washing between the operations were not so complete as they should be. Wash more completely before fixing and try the effect.

## EX CATHEDRA.

We give elsewhere the list of gentlemen chosen by the members of the Royal Photographic Society to judge next autumn's Exhibition of the Society. It differs very little from last year's jury. In the Art Section, Mr. Leader, R.A., replaces Mr. Wellington; in the Technical Section Captain Abney will act instead of Mr. Bulbeck; otherwise the names are identical. This is another instance of the curious conservatism of the Royal Photographic Society electorate. In the Pictorial Section the successful candidates were not all at the head of the list of nominees, three of those elected receiving fewer nominations than three gentlemen who were unsuccessful on the ballot. The result by no means represents the real feeling of the Society in the matter. Since May 31, when the ballot papers were sent in, we have received several requests to know the "latest date for voting." Many members who profess to take the keenest interest in the matter have not troubled to vote. It was entirely due to our efforts that a very large nomination list was sent out this year, and we are surprised that a proportionately large and representative ballot did not result, and that so much apathy was shown in so important a matter.

THE *Handbook to the Photographic Convention of the United Kingdom*, the Gloucester meeting of which takes place in the week July 10-15 next, has just been issued. It contains an excellent and characteristic portrait of the President-elect, Mr. William Crooke, and other illustrations, full particulars of the excursions, and a large number of notes and directions for the information of members. Mr. M. H. Medland contributes some interesting historical notes on Gloucester and neighbourhood, and a map of the town is provided. Last week we gave an outline of the Convention's arrangements for the week. In again expressing a hope that a large attendance and successful meeting will result, we have now only to add that the Hon. Secretary and Secretary of the Convention is Mr. F. A. Bridge, of East Lodge, Dalston-lane, London, who will be pleased to receive applications for membership, accompanied by the subscription, the small sum of five shillings a year.

\* \* \*

IN the current number of the Camera Club's *Journal* there are a number of critical notes, alleged to proceed from a committee of critics, on the photographs that constitute the members' Exhibition, now to be seen in the Club-room. The notes are brief, but they are calculated to be helpful, in their well-balanced praise and condemnation, to the gentlemen showing the photographs which are criticised. At the end of their notes the authors append the following protest: "We think it desirable to enter a strong protest at the growing disposition of amateurs to exhibit work which is not their own. It can only be considered derogatory to seek commendation for pictures which are not the production of those whose names are attached to them, and we fail to comprehend how any one desirous of doing artistic work can conscientiously confide the printing of his negatives to the trade enlarger."

\* \* \*

WE do not know what photographs the authors of this paragraph had in mind in penning their protest, which, of course, we have no intention of discussing *per se*, inasmuch as it relates to a purely private Exhibition; but we are, nevertheless, glad to see such a strong condemnation of a practice which is becoming only too increasingly prevalent. Last autumn we heard of many complaints as to the public exhibition of photographs which, after the production of the negative, could hardly be described as the "work" of the exhibitors, the

trade printer and enlarger being responsible for the prints. The rules of most open exhibitions provide that photographs submitted for acceptance must, up to and including the production of the print, be the work of the exhibitor. It is to be hoped that, where it is discovered that such a reasonable rule is broken, the offending exhibitor may be dealt with in such a manner that the action taken will deter others from attempting the form of dishonesty known as the assumption of borrowed plumes. In the hierarchy of the arts and crafts photography may be poorly placed, but let us keep it honest.

\* \* \*

THE next general meeting of the Röntgen Society will be held at 11, Chandos-street, Cavendish-square, London, W., under the Presidency of Mr. C. W. Mansell-Moullin, F.R.C.S. On Monday, June 12, eight p.m. Portable Röntgen apparatus for field and ward work, will be demonstrated and described by Major Beevor, R.A.M.C., Mr. J. Hall Edwards, and Mr. H. W. Cox. A new stereoscope will be demonstrated for Mr. Gregory, by Mr. F. W. Watson Baker. Dr. Walsh will also show a new stereoscope.

\* \* \*

IN connexion with the centenary celebrations of the Royal Institution, which have been held this week, Mr. W. Hugh Spottiswoode has been good enough\* to send us an illustrated book descriptive of the Spottiswoode collection of physical apparatus which the first-named gentleman has presented to the Royal Institution. The first part of the book is devoted to a brief appreciative memoir [of the late William Spottiswoode, who, up to the time of his death in 1883, filled a very large part in the world of physical science. He was President of the Royal Society in 1879, and, among other important offices, at one time held the Hon. Secretaryship of the Royal Institution. The apparatus here described is among the most magnificent that could be devised for the study of physical science, and the book, as a whole, is a worthy tribute to one who gave up a very large part of an active life to an examination of the problems [of light, electricity, and many other branches of physics.

\* \* \*

ACCORDING to an Australasian exchange the professional photographers of Auckland, (New Zealand) have held a successful and representative meeting, and have resolved to form themselves into an association to encourage unity in the craft and to raise the status of the profession. We heartily wish the movement the utmost success although its objects have the drawback of vagueness.† Unity is a very fine thing in its way, but what does it mean in this particular application of the term? Again, what loftier aim could there be than that to raise the status of a profession, but how is it to be done? It is in no carping or hostile spirit that we ask these questions—the same things have been talked and written about and occasionally attempted in Great Britain, absolutely without success. English photographers appear incapable of combining and holding together for purposes of mutual help and advantage; and all the efforts that are put forth to rid them of this disability seem doomed to be fruitless. It has long since passed into proverb that the professional photographer of these islands is like the bird quoted by Lord Dundreary, he prefers to "flock all by himself." Still, we wish the Auckland photographers success in their, doubtless, well-meant efforts to

help each other; and we shall be agreeably disappointed if these efforts escape the usual fate of failure.

\* \* \*

VERY many of our professional readers knew the genial and energetic Arthur C. Baldwin, who for some years past has been the country representative of one of the most respected houses in photography—The Paget Prize Plate Company of Watford. Owing to some changes in the *personnel* of the Company's staff, Mr. Baldwin will in future represent his firm in London and the South. Mr. Baldwin is an admirable man of business, and we wish him well in his new sphere of work.

\* \* \*

MR. C. M. HEPWORTH, who has long been known as an expert in cinematography, has recently commenced business at Hurst Grove, Walton-on-Thames, under the name of Hepworth & Co., cinematographers. In the design, construction, and manipulation of cinematographic apparatus there is nothing that Mr. Hepworth does not understand. The new firm start with the aim of making animated photographs, and are thoroughly equipped for the work. We wish Messrs. Hepworth & Co. the utmost success in their undertaking.

\* \* \*

MR. ALFRED SEELEY, of 22, Haldon-road, Wandsworth, informs us that he has opened an office for a professional and business agency at Regent House, Regent-street, W., to register particulars of all professional or business vacancies or applicants for the same, and for the sale of businesses in town or country.

\* \* \*

THE *Strand Magazine* for June, which is a double number at the price of 1s., is noticeable for a chatty and informative article on the use of the Röntgen rays in warfare, which is illustrated by reproductions of many radiographs. The subject has already been authoritatively dealt with by Mayor Beevor at the Camera Club and elsewhere; but, in the article before us, it is presented in a more popular fashion. Of the monthly magazines the *Strand*, perhaps, makes the most lavish use of photography, for which it invariably has a kind word.

\* \* \*

ACCORDING to the *South African News*, the Capetown Photographic Club recently held a most successful open Exhibition. It was visited on the first day by over 1000 persons. The opening ceremony was performed by the famous artist, Lady Butler (better known by her maiden name of Elizabeth Thompson). The Exhibition was entirely free, and it appears to have been locally regarded not only as an interesting social function, but as an important contribution to the cause of photographic progress in South Africa. We congratulate the Capetown Club on their admirable efforts, and trust it will organize similar exhibitions in the future.

\* \* \*

IN another part of this week's JOURNAL we reprint, from the last number of the *Journal* of the Photographic Society of Philadelphia, the report of a discussion on Professor Wood's ingenious system of colour photography by means of diffraction gratings, in which the Professor himself, Mr. Ives, and other gentlemen took part. Many interesting points concerning the practical applications of this novel and beautiful process are referred to. In a note received from Professor Wood, he tells us that he is shortly publishing something in this country on the process, which seems to be developing in a satisfactory manner.

## DARK-ROOM ILLUMINATION.

As the photographic season may now be considered as opened out, and the ever-increasing army of amateurs setting their houses in order for a long campaign, the present is an opportune time for a few words on a very important factor in photographic operations—the dark room and its lighting. We are led to make some observations on the subject through having recently met with no inconsiderable number of cases where advice was much needed—cases where, of all others, it might have been thought, *à priori*, that the particular house was bound to be set in order, not amateurs houses, alone, singular to relate.

It goes without saying that the first requirement, as regards the illumination, is virtual safety, and, next, to have as much light as possible so long as the first requirement is satisfied. Lord Palmerston defined dirt as “matter in the wrong place.” An unsafe light may be described in similar language as light in the wrong place. The search for a safe light is a complete *ignis fatuus*, as futile as the search after perpetual motion. Ordinary dry plates are sensible to all radiations giving visible light, but, naturally, not to the same degree. Hence, when we speak of the two requirements as virtual safety with a maximum of light, it must be understood with the qualifications expressed.

But it is one thing to have light shining directly upon the plate, and another to have it lighting the dark room generally, so as to enable the operator to see with comfort what he is doing and where everything lies. This is no slight matter when there is much work to be done; many a negative is broken or scratched through working in darkness, when a sufficiency of light might be employed without danger. It follows from this that a good, fairly strong light may be used in a room, provided the handling and developing of plates is not carried on too close to it. A recollection of the well-known rule as to the intensity of light varying as the square of the distance from the source will show, for example, that, if a certain light caused fog on a plate after five minutes' exposure to it at a distance of a foot, it would need three-quarters of an hour's action to produce an equal amount of fog when no more than a yard away. We wish to make a particular qualification with regard to this rule; it is only applicable when the source of light is small, such as a gas or lamp flame, or an electric light. It is entirely inapplicable to windows of some considerable area, say, whose linear dimensions are such that a possible retiring distance is only a few times larger than the height or breadth of the window. It is important to note this, for the error both as regards dark-room windows and studio lights has been one of frequent occurrence in photographic literature.

It will naturally be a question for consideration whether the light should be an artificial one or natural daylight. The latter costs nothing; but that, indeed, is its chief advantage; for, seeing that certainty of results is nearest the greater the uniformity of working conditions, it is obvious that a source of light practically constant, such as gas or oil light, must be more uniform than the capricious light of sky or clouds, and especially is this useful in judging density. An artificial source has also the advantage of portability, the illumination can be had exactly in the direction or at the point needed. The convenience of having the light always ready, during the hours of day at any rate, will always weigh, and daylight as one source will frequently be chosen, though it may be suppl-

mented by gas or other combustion. One point, however, with regard to the use of a window bears on the question of safety, and that is its size. We remember a singular example. A well-known photographer was troubled with fog in a new dark room he had built, but could not believe its source to be the window (glazed with ruby glass), for the glass was from the identical stock from which his old dark room, in use for years, had been glazed. Yet, eventually the evil was traced to the window; the new one was many times larger than the old one, and so let in a proportionately greater quantity of light. In one case a twelve-inch pane had sufficed; in the other, a large window five feet by three was glazed, and thus let in fifteen times as much light as the former. It needs no argument to show that a light area, too feeble to fog in reasonable time when its dimensions were small, might easily do serious injury when the light upon the plate was fifteen-fold greater in quantity. It is evident that the true meaning of a safe light had not occurred to the gentleman in question.

Turning now to a consideration of the colour of the light employed, though mixtures of yellow and green are still employed by some, it is yet a fact that, owing to the exiguous character of the quick plates of modern make, the general consensus of opinion is in favour of a ruby tint. It is, however, singular that to get double-flashed ruby is most difficult—it is not often stocked even by the large houses of the trade—while to get a sample of glass flashed with ruby on one side and orange the other is almost impossible; yet, although the latter gives more light, its actinism is greatly below the double ruby. It is commonly admitted that a light-filterer of these two colours is superior to one of ruby alone.

For this reason, if a window is covered with fabric of one or other kind, it is always desirable to put a double thickness, one being of red or ruby, and the other of orange or yellow. There is a caution worth giving in regard to the addition to existing windows of coloured media. There is always danger of leaving light leakages in one place or another, and, when a window is covered with its ruby screen, enough coloured light comes through to mask any possible white light either at the window itself or in its vicinity. If, however, a large piece of brown paper, just the size of the ruby protector, be placed over the latter temporarily, the room will be plunged in temporary darkness, and the slightest trace of white light at once detected.

We have now touched upon the most important points in connexion with the subject indicated by the title of this article, and our work will not have been in vain if we have only enabled the average photographer to realise the true inwardness of the term “safe light.”

**Dark-room Windows.**—In reference to the foregoing subject and the use of daylight in dark rooms, the window is frequently covered up with one or other of the fabrics sold for the purpose, and perfectly safe most of them are when they are new, but not so after they have been exposed to the light or a long period; they change, though the change is not noticeable from the inside of the room, as the colour does not in the majority of cases bleach out, but changes to a brown. The fabric by this change loses its non-actinic character, though it does not admit any more light. Hence the change, as we have just said, passes unnoticed and unsuspected till trouble arises. We call attention to this matter because two or three instances have recently come under our notice of trouble from this source and batches of plates being condemned as being foggy. In

the cases just referred to the windows were covered up last summer or spring, and the fabrics, with two or three thicknesses of them, were perfectly safe; but the summer light had its effect, though no ill was discovered during the feeble light of the winter and early spring months. But the case was different with the brilliant light we have been having the last month or two. Then trouble from an unexpected source was experienced. Those who use daylight in their dark rooms, and employ fabrics for the window, should periodically examine them to see if they have undergone any change, whether apparent to the eye from the inside or not.

**The Chlorate of Potash Explosion.**—When noting this catastrophe three weeks back, we mentioned that the chlorate, *per se*, was not explosive, and we should await with interest the evidence given at the inquest. Last week the inquest on the remains of the five unfortunate victims was concluded, but, from the reports that have appeared in the daily press, very little actual light was thrown on the real cause of the explosion of the chlorate. The manager of the works, in his evidence, said that over 150 tons exploded, but he had, like most others, never regarded chlorate of potash as an explosive. When asked why so much of the salt was stored near the drying, milling, and cooling rooms, he said that it had hitherto been considered free from explosive effects, and that, in his opinion, the explosion was brought about by the mixture of gases caused by the fire. It will be remembered that the explosion was caused by a fire that originated in an adjoining building. This opinion was endorsed by the manager of another chemical factory. In the end the jury, after due deliberation, returned a verdict of accidental death, with a rider to the effect, amongst other things, that chlorate of potash should be stored in quantities limited by Government control.

In the days when lanternists and photographers had to make their own oxygen from the chlorate of potash, accidents sometimes happened, but they were usually attributed to carbonaceous matters in the manganese which was used with the chlorate. But there could be no such matter in the chlorate that exploded when it was made, so that they must have become introduced during the fire in some form or other—according to the opinion of the witnesses—in the gaseous form. Many will, no doubt, consider that the evidence as given at the inquest does not fully account for the explosion of the chlorate of potash, which has hitherto been considered a non-explosive, and by itself a harmless material.

**A Photographic Expedition.**—The Vienna correspondent of the *Standard* says that the Vienna Academy of Science has decided to send a party of astronomers to Delhi for the purpose of photographing Leonides. The photographs are to be taken at two different places several miles apart. The Vienna Academy is an exceedingly enterprising body, in the interests of science we would that we had several such in this country.

**Another New Element.**—It is announced that Mr. Edward Lippman, Professor of Chemistry at the Vienna University, has discovered another new element, and that he has informed the Vienna Academy of the fact. In due course, according to its customs, the details of the discovery and of the new element will be published by the Academy. The publication will be looked forward to with interest by all scientists. Years ago all the elements were thought to have been known, but with the advancement of science new ones are continually being discovered. We wonder if this latest addition will have any photographic interest?

**International Copyright.**—The official *Reichsanzeiger* has notified that Japan has joined the International Copyright Convention, concluded at Berne in 1886, as well as the Supplementary Convention of 1896. Henceforth all works of art, including photo-

graphs, copyrighted in this country will be copyright also in Japan; also, all works copyrighted in Japan will be copyright here. In this matter Japan sets an example to some other countries—America, for example, which has hitherto held aloof from the Convention. It is notorious that English and Continental works are systematically pirated as soon as they arrive in that country, so much the worse for the English and Continental publishers.

**Modern Etchings.**—Last week, at a sale of prints, one of Whistler's early etchings, *The Engraver*—a portrait of either Rioult or Carpentier—was knocked down to a New York gentleman, after a spirited competition, for the sum of 72*l*. This, we believe, is really a record price for an etching sold "under the hammer" during the lifetime of the artist who produced it. Higher prices have been realised for modern etchings, but only after the artist's death. For example, some of Merion's have been sold for over a hundred guineas each, but only after his death. It is said that for some of these Merion during his lifetime was glad to receive only a few shillings each. One wonders what the best photo-etchings will realise if brought under the hammer after their producer's death. It is a noteworthy fact that our American cousins often pay the highest prices to secure works of art by the best artists. Some of our best works have left this country for America from time to time, but always at a high price, often, it is said, far beyond their value. Old line engravings and mezzotints by the best engravers always fetch high prices, but that is partly accounted for by the fact that line and mezzotint engraving has become almost an extinct art. The old workers have died off, and there are few or no new ones to take their places. Photogravure is, no doubt, accountable for much of this, condemned as it is by artists, or, rather, art critics.

**Pigeons as Letter-carriers.**—Last week it was announced in the daily press that a carrier pigeon was found dead in a garden at Hythe. It was the bearer of some thirty messages from passengers on the liner *La Gascogne*. Some of the letters, it is said, were in English and some in French; and they were contained in a thin piece of celluloid and were reductions by photography, so that the aid of a microscope was necessary to decipher them. The liner, says the report, was fifty miles west of the Scilly Isles when the bird was dispatched. Some may probably look upon this as an entirely novel idea, whereas it is quite an old one. During the Paris siege the pigeon post was a regularly established thing—indeed, it was the only means of communication with and from the outside. Reduced copies of the messages, several on a plate, were made by the wet-collodion process, and the films were afterwards stripped off the glass. A number of these were put into a quill, which was then attached to the pigeon, and it was dispatched. On arrival the films were put into the lantern and projected on the screen, sufficiently large to be read. They were then rewritten, and sent on to those for whom they were intended. Quite a large number of these films, each containing several letters, were contained in each quill, and they only weighed a few grains, the collodion being so very light. Hence it will be seen there is no novelty in pigeons being the bearers of letters reduced by photography.

#### AMMONIUM PERSULPHATE.

As you have published in the valued columns of *THE BRITISH JOURNAL OF PHOTOGRAPHY* my article upon persulphate, likewise the correction I sent you, and the reply of Messrs. Lumière, which first appeared in the *Bulletin de la Société Française*, I trespass once more upon your kindness by asking you to publish the following:—

The remarks which I made concerning the theory propounded by Messrs. Lumière, as to the action of persulphate of ammonium, have provoked a reply, which I think fails to dispense the doubts which I raised.

I asserted most emphatically that the action of ammonium persulphate upon a solution of silver salt forms a compound by decomposition (probably a sub-sulphate of silver, but never, according to my experience, metallic silver). As I have already said, this can easily be proved, by observing that the precipitate is rapidly and completely dissolved by

hyposulphite of soda, and gives up sulphuric acid to the water. Consequently it cannot be maintained that, in addition to the solvent action of the persulphate upon the silver at the surface of the plate, there is a corresponding inverse reductive action of the persulphate upon the sulphate of silver formed, by reason of which metallic silver tends to be precipitated. Under any circumstances this precipitate could only be a sub-sulphate of silver. On the other hand, I have found that a large excess of persulphate, in presence of a very small quantity of silver salt, does not form any precipitate. I think the experiment, mentioned by the authors in their reply, does not detract from the importance of this fact, also that it lends no support to their hypothesis. It is quite true that a solution of silver sulphate, whether prepared by decomposition of persulphate in presence of a reducer, such as pyrogallol or hydroquinone, or otherwise, causes an intensification of the negative by deposition of metallic silver upon the image. This we should expect. But the reducing action of pyrogallol (or hydroquinone) cannot be compared with that of persulphate.

The former, without doubt, forms a deposit of metallic silver, but the latter, as I have proved, never forms a deposit of metallic silver, but a product of reduction (sub-sulphate). Moreover, it should be noted that pyrogallol, in presence of a soluble silver salt, acts as a reducer, independent of the proportions of the two substances, whilst persulphate does not exercise a reducing action when in very large excess. I would also draw attention to the following fact, mentioned in my first paper upon the action of persulphate. I found that not only did a neutral solution of persulphate act as a reducer, by first attacking the denser portions of the negative and afterwards the half-tones, but that the same effect was obtainable with an ammoniacal solution of persulphate, although the action was considerably slower. Now, whatever quantity of silver salt be added, an ammoniacal solution of persulphate of ammonium forms no precipitate of metallic silver or any other product of reduction.

In a paper which I read on May 18 at the Italian Photographic Congress, at Florence, I spoke at length of the use in photography of a solution of permanganate of potash and sulphuric acid, and I stated that a very dilute solution acted as reducer of the photographic image in a manner somewhat analogous to persulphate. In this case there is no ground whatever to suppose that silver is deposited upon the image.

I must therefore repeat, that, in my opinion, the true cause of the selective action of persulphate still eludes us. PROFESSOR R. NAMIAS.

#### DIFFRACTION-GRATING COLOUR PHOTOGRAPHY.

At the last meeting of the Photographic Society of Philadelphia, as reported in its *Journal*, Professor Wood said that he had some hesitation in consenting to show the very crude results obtained thus far by him in the attempt to reproduce the colours of nature by diffraction, and that, after seeing Mr. Ives's beautiful pictures, he had still more hesitation. He explained that his pictures were the result of three weeks' very hasty experimental work and were extremely crude. Whether it would be possible to make them any better, or to develop the process any farther, he did not know, but it was extremely interesting to get a picture in colour by an entirely new method. The idea occurred to him, in endeavouring to think of some way in which the surface of glass could be impressed with a structure which would send light of a certain colour to the eye, and then to impress on it another structure to send another colour to the eye without interfering with the first colour. In the three-colour process, it is impossible to use the three colours by superposition; if green and red gelatine films are superposed, black, and not yellow, is the result, because the coloured lights are not mixed. By means of a diffraction grating it is possible to produce a surface which will send two different colours to the eye at the same time.

The principle of the process is as follows: If we take a glass plate ruled with very fine equidistant lines by a dividing engine, this plate of glass has properties somewhat similar to a prism. If we place in front of a lens such a glass plate, then, instead of the lens forming simply an image of a source of light, such as a lamp, there is formed in addition to this image a series of rainbow colours on each side of it, the blue light on the end towards the centre and the red farthest away. If we perforate the screen on which the spectra are thrown, light the perforation with the blue of one of the spectra, and view the grating through the hole, it will appear blue. The same is true for the other colours, that is, the colour of the grating depends on the position of the eye. Now, the greater the number of lines in the grating, the farther the spectra are thrown from the centre, so that, by using three gratings, one over the other, one having about 2000 lines to the inch, one 2500, and one 3000 lines to the inch, the red from one grating, the green from another, and the blue from another grating can be thrown on the same spot, and the eye will see the grating illuminated by a mixture of the three, that is, by white.

Then, if we have a grating on which the ruling is not uniform—say, a band ruled with 2000 lines, another with 2500, and another band with 3000—if viewed properly, the grating will appear as three bands of red, green, and blue.

If, now, we have a plate with a design of a tulip blossom with leaves growing in a pot, and the blossom has 2000 lines to the inch photographed on it, the leaves 2500, and the pot 3000, and we view this plate as described, we shall see a red tulip with green leaves in a blue pot. Thus we see how a coloured picture can be formed of diffraction gratings.

So far, Professor Wood said, he had not attempted to produce one of these grating pictures in the camera, the three-colour records being taken separately in the usual manner, through red, green, or blue filters. From these, three ordinary lantern-slide positives were made. The positive, representing the action of the red rays, is placed over the diffraction grating rule with 2000 lines to the inch, and then there is placed under that a piece of ordinary glass flowed with a solution of gelatine and bichromate of potash. The sunlight goes right through the transparent parts of the picture, and prints on the film an image containing 2000 lines to the inch. This operation was repeated for the green and blue. The lines thus formed are quite invisible. Then we have, as a result of this triple printing, a transparent picture with very fine lines distributed according to the colours of the original.

If the plate is then placed in front of a lens, we will get red from the coarse grating, green from the intermediate one, and blue from the fine one.

Now, if we take another plate of glass and flow it with bichromated gelatine and place it in contact with this and hold it in sunlight, at a single printing process we shall have produced on that plate, in just the right places, exactly the same arrangement, and we can print another one from that. The copies will be positive, and cannot be distinguished from each other.

Professor Wood went on to say it had occurred to him that, if a suitable photographic plate could be found, it would be possible to produce in the camera, on one plate, a finished photograph of this kind, which should be seen as a positive. That might be accomplished in this way: if a photographic plate is exposed in a camera in succession, through red, green, and blue screens, or ray filters, on the surfaces of which diffraction gratings of 2000, 2500, and 3000 lines to the inch are ruled or photographed, then the parts of the picture which are red would be impressed with 2000 lines to the inch, the green with 2500 lines, and the blue with 3000. This would require a photographic plate of very fine grain, which would be at the same time sensitive to red light. It remains to be seen whether this can be done. At present the colours obtained are too brilliant. The development of the process is simply a question of surmounting the mechanical difficulties in photographing the gratings.

Mr. Redfield remarked that he was sure that every one had been delighted with Professor Wood's lucid explanations, and asked if any one had any questions to ask.

Mr. Carbutt asked Professor Wood whether it had occurred to him to use a rotating plate or a moving sensitive film in taking the pictures of the sound waves.

Professor Wood replied that he thought nothing would be gained by that, as there was no great necessity for uniformity of motion, it only being necessary to move the plates enough to get the images separated, which could be done just as well in the simpler way.

Mr. Frederic E. Ives said: Professor Wood's method of colour photography is not an easy one to explain so that everybody will readily understand it, but his explanation of it has been remarkably good and clear, and the originality and theoretical soundness of the procedure must be evident to everybody who is familiar with the subject. It is, of course, another variation of the trichromatic process of colour photography, already well developed along other lines; but it is the most striking and original method of carrying out the principle that has been suggested in a long time.

The idea of producing a colour record in three photographic images is now about thirty-seven years old, and it is more than ten years since I first reduced it to really successful practice by working to the Maxwell colour curves; but there remained the problem of means of synthesis calculated to meet all the requirements and wishes of the public. In the Kromskop and triple-lantern projection we have optical synthesis with three uncoloured photographs and three colour screens; in the so-called Joly or MacDonough process we have optical synthesis with a single image and a single screen, which may be described as linear mosaics of the three photographs and three-colour screens of the other methods; in typographic and gelatine "three-colour printing" we have synthesis by superposed transparent colour prints; and now Professor Wood gives us optical synthesis with a single print, without colour or colour screens, but requiring a special viewing device—distinctly a new departure.

There are evidently some technical difficulties to be surmounted, and only by actual experiment can the practical importance of these difficulties be determined. One difficulty which occurred to me was that of securing variation of intensity of colour proportionate to the depth of printing of the diffraction lines in the gelatine or albumen film; after printing to a certain depth, longer printing does not increase the brilliancy of the diffraction spectrum obtained, and it is a question

whether the full scale of gradation of the photograph can be reproduced by means of a print made in diffraction lines. This question has an important bearing upon the reproduction of the ordinary compound colours of nature. Professor Wood has told me that he recognised this difficulty, and that within certain limits of exposure he had been able to obtain gradation in the image corresponding to variations in the density of the photographic positive from which he made the diffraction line prints.

Professor Wood now makes his original colour record as the Kromskop colour record is made, but makes the very interesting suggestion that the diffraction lines might be impressed upon the plate by the initial exposure in the camera, in which case a single picture would be produced which would be ready to show the colours as soon as developed and fixed. Assuming the possibility of securing satisfactory gradation of light and shade with a diffraction line print, this idea is perfectly feasible from a theoretical point of view; but it cannot be accomplished with ordinary photographic sensitive plates.

Colour photography has been very much in the air during the past ten years, announcements of alleged new processes appearing every few months, followed by glowing newspaper accounts. In most cases there has been a great air of mystery about these alleged discoveries, and we have waited for months, in some cases years, before finding out that these methods were either fraudulent or not really new, but applications of the trichromatic theory with unessential modifications, which, as a rule, are not even improvements upon published methods. It is, therefore, very refreshing to have somebody bring forward a really new and original idea, and Professor Wood is to be congratulated upon having made the most original suggestion that has been made for a long time.

Professor Wood: In regard to the possibility of getting the pictures with one exposure in the camera, I find that I can get a record of a single set of lines by exposing a plate under the coarsest grating and developing it; viewed in the viewing apparatus, it showed as a positive, although the brilliancy could not be compared with the original. I do not think, however, it would be possible to secure, on an ordinary plate, three different sets of lines superimposed, the grain is so coarse that it could not take much more than a single set of 2000 to the inch. I believe, however, that possibly with a plate somewhat similar to the Lippmann plate—or something between a Lippmann plate and an ordinary dry plate—something might be done. I do not know whether plates of that kind can be made sensitive to red. Mr. Ives can tell us.

Mr. Ives: The Lippmann plates are made sensitive to red.

Professor Zeokwer: I should like to ask Professor Wood whether he has succeeded in photographing a musical sound?

Professor Wood: No, that has not been tried. The trouble is, that the condensation is not sudden enough. It might possibly be done close to a vibrating string, but my impression is that the condensation would not be sudden enough. The crack of the spark gives a very sudden blow to the air and a very sudden condensation. I doubt if the condensation in an ordinary musical note would be sufficient. Of course, the waves of musical notes can best be photographed by photographing flames thrown into motion by them, which only show, however, the changes of the flame, owing to the sound, and not the waves themselves.

George Vaux, junr., said it seemed to him that what Professor Wood had said and done was really epoch-making, and the Society was to be congratulated upon having had the opportunity to hear Professor Wood and see the results of his brilliant work. He therefore moved that the Society tender to Professor Wood a hearty vote of thanks. It was unanimously agreed to, and the Society then adjourned in order that the members and visitors might examine the colour specimens arranged for their inspection.

## STEREOSCOPIC PHOTOGRAPHY.

[Paper read before the London and Provincial Photographic Association.]

I TRUST I may be excused for once more bringing this time-worn subject before your notice, my object in doing so being, if possible, to add a few more recruits to the stereoscope and stereoscopic photography. Since my conversion to this branch of our photographic art, it has become more than ever a matter of surprise to me that so few amateurs have added to their stock of apparatus a stereoscopic outfit. I am afraid this is largely due to the fact that there are but few who ever take the trouble to dive into the difficulties, real or imaginary, that are said to surround stereoscopic work. There can be no two opinions—at any rate, amongst those of us who possess binocular vision—as to the enhanced value given to a photograph by its being represented in all the solidity and reality that stamp the good stereogram. Nothing but colour would be wanted to complete the illusion that we were really looking at the object itself, and not its reproduction only, if the size were for the moment forgotten. I am convinced that, if it were well understood that there is practically no more trouble involved in the taking of a stereographic picture than in the making of an ordinary quarter-plate, the present disparity in the popularity of the two sizes would no longer exist. I propose to offer a few hints that I hope will help the would-be stereoscopist, and will deal

first with the selection of size of plate. I strongly recommend that known as double quarter-plate ( $6\frac{1}{2} \times 4\frac{1}{2}$  inches). The selection of this size enables the stereoscopist to rid himself of the constant fear that he will be unable to obtain supplies anywhere he may happen to be, especially if touring. He will find that he can use two quarter-plates as readily as the uncut  $6\frac{1}{2} \times 4\frac{1}{2}$ , which can be purchased anywhere. Further, if he finds a subject that his experience or instruction teaches him would not make a good stereogram, he has the possibility of making an ordinary quarter-plate negative by uncapping one lens only, reserving the other plate for a similar opportunity to offer. This size also allows margin for trimming the print, either in the sky or foreground, to suit the composition of the subject. This, in practice, will be found invaluable, as the best of us, especially when taking snap-shots by the aid of a finder only, do not always get our picture balanced exactly as we should like; and with the older size of stereo plate,  $6\frac{1}{2} \times 3\frac{1}{2}$ , we should have to put up with what we had got, the margin for trimming being *non est*. Further, in the latter size of plate there is no practical advantage in the additional  $\frac{1}{2}$  inch base-line measurement, as it will be found that the finished stereo print should not exceed 8 inches square, the extra length consequently having to be trimmed away; another disadvantage is that this size is rarely stocked by any photographic dealer. I do not wish to be understood as recommending that two quarter-plates be used in preference to the uncut plate, as the latter is more convenient in practice; I merely put forward the method as the best when there is likely to be any difficulty in obtaining supplies.

The size of plate having been decided upon, the next, and one of the most important requirements, is a good camera. This may be either a hand or stand camera; but, whichever pattern be selected, I strongly advise it having means for focussing. There are now on the market many patterns of combined hand or stand cameras which are very portable and compact. I personally use one of my own design, which may be used indiscriminately as a hand or stand camera. It is, as you see, somewhat less bulky than an ordinary quarter-plate magazine camera, with the exception that the slides are a separate package, and is well suited for ordinary snap-shot photography, which forms four-fifths of my work.

Whatever the pattern camera selected, it must have a good shutter, capable of giving time or instantaneous exposures, and my own choice is a Thornton-Pickard Behind lens pattern with adjustable centres to panels. It would also be advisable to have a safety blind fitted, as in this pattern the cord flies back into the shutter after setting, a most desirable detail, as bitter experience in the catching up of the cord has often taught me. There are various patterns of magazine hand cameras built for stereoscopic work, but there are many objections to the type, the first point to remember being that you have the equivalent of two dozen quarter-plates to carry about instead of one dozen. You have no focussing screen, and often no rack and pinion. This latter point is most important, as the best stereoscopic effect is obtained with objects often within the infinity focus of the lenses. Also to the changing movement of a magazine hand camera has to be added means for removal of the septum or dividing chamber before the plate can be dropped into the well. This point, of course, does not apply with bag-changing cameras. On the whole, I think dark slides are much to be preferred, although somewhat slower in use.

To complete the outfit, a well-matched pair of lenses is necessary. These must be matched, not only as regards their focus, but as regards their intermediate apertures, the latter error being more common than is usually credited. Nothing is more annoying than to find that, when, say, you have stopped both lenses down carefully to *f*-16, one half of your negatives develops much denser than the other, with consequent unevenness in the resulting prints. Either the wheel or the Waterhouse diaphragms are the least liable to error, and of the two I prefer the wheel. However, nothing can equal a good Iris for comfort in working, subject to the proviso that its apertures be accurately engraved on both lens mounts. Respecting the type of lens preferably to be used, I must confess that I see nothing in stereoscopic photography that differs sufficiently from other forms of photography to influence the selection of lenses. I advise the purchase of the best lenses that the depth of one's pocket will permit, remembering always that we may elect to enlarge one of the two quarter-plate pictures that form our stereoscopic negative, just as we should enlarge any other particularly successful quarter-plate negative in order to see it to best advantage. Therefore it is inadvisable to purchase cheap lenses unless obliged to. I have frequently noticed the recommendation of landscape lenses for use in stereoscopic work, but for what reason, excepting price, I am quite at a loss to see. My own experience points to the fact that architectural subjects, street scenes, &c., will form a large element of our exposures, and certainly it is not here that the landscape lens will shine.

The question of suitable focus for our lenses is one that need not cause much thought, practically any focus that would be suited to quarter-plate hand-camera work will do equally well for stereoscopic work, an abnormally wide-angle lens should, however, be avoided, as a good proportion of our most suitable work will be fairly close to the camera, and strained perspective is well shown up in the stereoscope. All stereoscopic cameras should be fitted with a spirit level, as no deviation whatever from the perpendicular can be permitted. Amongst the subjects

best suited to stereoscopic treatment may be classed architectural work, street scenes, yachting and shipping studies, landscapes when not embracing too large an area, and flower studies. I venture to assert that no photograph, however well taken with one lens only, of a bunch of flowers can compare with even a very moderate rendering of the same bunch taken stereoscopically. You can look into the very petals of the flower, measure its area and gain an accurate idea of its beauty. The important point of separation of the lenses should here be considered, for very near objects, such as the flowers before mentioned, the centres may have to be closed down to as little as  $2\frac{3}{8}$  inches to avoid exaggerated relief, whereas, for objects at a considerable distance from the camera,  $3\frac{1}{2}$  inches would not be excessive, and in extreme cases, where the view is very distant I have known, of exposures being made with either lens from two distinct standpoints, on the one view. I find, however, that for all-round work out-of-doors 3 inches is the best working separation, and is one that will not show too great a difference in the amount of subject on the respective halves of the plate. No stereoscopic camera should be purchased that does not give the power of altering the centres of the lenses, it is in my opinion quite as important as being able to alter the speed of the shutter.

Having now dealt with the most important features that should be present in the stereoscopic camera, I propose to consider the actual making of the Stereogram. I suppose there can be but few photographers who have not at some time or other examined a batch of stereoscopic prints, and this examination will have undoubtedly revealed a fault which is all too prevalent, viz., snowiness, an effect which is decidedly out of keeping when looking at a landscape with trees in full foliage. The cause is almost always under-exposure, combined with over-development, or may be due to the latter cause alone. The remedy is obvious. In stereoscopic photography, more perhaps than in any other branch of our art, correct exposure is a desideratum. Even an exposure which would be considered too much for ordinary work will often turn out in the stereoscope to be all that could be desired; therefore the stereoscopist will be well advised, if bent on using his camera for snapshot work, to purchase as rapid a brand of plates as possible, and thus minimise his risks of under-exposing. If in spite of this he finds he has an under-exposed negative to deal with, it will undoubtedly be policy to push shadow development to the utmost, keeping density as much in the background as possible and relying upon the power of judicious printing, and, after sunning off, to soften things down. I am always inclined to look upon the actual development of the negative as a somewhat mechanical operation and of quite secondary importance to the question of exposure. This especially applies in stereoscopic work, and, if an approximately accurate exposure has not been given, no amount of after-treatment of the plate that I know of will prevent that fact becoming known when the resulting print is viewed in the stereoscope.

A method which I have often adopted when dealing with a negative that has been strongly lit and perhaps somewhat over-developed, and which consequently gives a harsh print and the objectionable snowiness, is to reconvert the deposit forming the negative with the following solution:—

Potash ferricyanide .....	100 grains,
Potash bromide .....	100 "
Water to .....	10 ounces,

into which the negative is immersed (after being allowed to dry in the usual way) until acted upon right through to the glass, washed for twenty minutes in running water, and dried as usual. It will then be of a rich deep yellow colour, and will print exceedingly soft.

The next point to consider is trimming the print. This usually takes so much description as to give the impression, to one who has never attempted it, that it is an extremely complicated and tiresome operation. It certainly is an operation requiring more care than the trimming of an ordinary print, for the reason that, unless absolute accuracy is observed in trimming both prints exactly through the same baseline, the effort to merge them in the stereoscope will cause great distress to the eyes. It must also be noted that, on looking at the print as it faces you waiting trimming, the picture on the right hand will be that taken by the left lens, and *vice versa*, consequently it becomes necessary to reverse when mounting, in order that the right print on the mount be that one taken by the right lens, and again *vice versa*. All this is obviated, of course, if the negative itself has been cut and transposed, but I do not think, excepting when printing on a wholesale scale, that this method will recommend itself to the average amateur. The system of working which I invariably use, and which I propose to show to-night, is to turn the print over on its face, and mark on the back the letters *a* and *z* in their proper positions. I then take my cutting shape, which measures  $6\frac{1}{2} \times \frac{3}{4}$ , place it on my print, and note that an object appearing in the foreground of both pictures is exactly covered by the edge of the shape. I then trim all round the four sides of the shape without moving it, to facilitate which, incidentally, I may recommend a revolving cutting table; then, without lifting the shape off the print, I slide it along to the left, thereby uncovering the right print, until I reach the mark created by the septum in the camera; I draw the knife down again and one print is finished. Still, without raising the shape, I slide a trifle more to the left, and cut

away the septum mark altogether, and the other print is then ready for mounting. This description seems somewhat lengthy, although, as a matter of fact, the actual operation of trimming is performed well under one minute. It is, perhaps, hardly necessary to remark that the cutting shape used must be absolutely true on all its sides, and such a shape, when once secured, is well worth taking great care of. The size mentioned,  $6\frac{1}{2}$ , allows three-sixteenths of each side of the length of the plate being absorbed by the rebate of the dark slide, which allowance should be ample in well-made apparatus.

Having trimmed a batch of prints, the next operation is mounting; here there is undoubtedly room for a diversity of opinion as to whether the wet or dry method is the best. I propose to show you the method I always adopt: Firstly, all prints, previously toned, dried, and trimmed, are gathered together in pairs and placed in a half-plate granitine dish to soak for about five minutes; the prints marked *a* on the right side of the dish, one on top of the other, and those marked *z* on the left; after soaking they are gathered up in two separate piles, and placed each pile face down on a piece of clean glass, *a* prints on the right, *z* prints on the left, and superfluous water duly drained off. Then, having the mountant ready, either starch on one of the white dextrine mountants, of which so many brands are now on the market, and a good hog's-hair brush about one inch in width, also two pieces fluffless photographic blotting paper such as "Robosal," I blot off the top pair of prints as they lay on the pile and apply the mountant. I then pick up the print marked *z* and place on the mount, with its inside edge against a pencil dot which I have previously marked on the exact centre of the mount. I do not trouble at that moment to press the print down, but proceed to pick up from my pile the fellow print marked *a*, and place in position on the mount with its edge touching the other, which, being done, I place my piece of dry blotting paper over the whole, and rub down fairly heavily. The final finish I adopt is by burnishing with a nickelled roller-burnisher, heated by a blow-lamp burning methylated spirit, the cost of which was 2s. 6d.

It is, perhaps, needless to remark that, if the gelatino-chloride process is used for producing the prints, they must be well alumed. It will be observed that there is always a difference in the actual amount of view showing on either print; this difference is easily understood when it is remembered that, although the two exposures are made simultaneously, the actual point from which the view is taken by the two lenses varies with the amount of their lateral separation. If the correct separation has been used between the lenses according to the distance of the object photographed, the method of trimming I have previously mentioned will prove perfectly satisfactory, no additional marginal trimming being required, and it will be found that there will be somewhat more of the view included on the left side of the right picture than on the left picture and *vice versa*.

The prints, when mounted, will vary in the centres from  $2\frac{1}{2}$  to  $3\frac{1}{2}$  inches, but nearly every individual will find the most comfortable centering will not exceed three inches. As far as printing surfaces go, our choice will have to be somewhat limited, and unquestionably the best media will be one of the glazed gelatino-chloride or albumenised papers. I have seen some fairly satisfactory results both on carbon and glazed bromide papers, but do not think either of these processes quite equal to gelatino-chloride for stereoscopic work. Anything in the nature of rough or semi-rough surfaces should be avoided, as the effect is exaggerated in the stereoscope. Perhaps the best method of viewing a stereogram is to make a transparency on either glass or celluloid; there is no very special difficulty in this to any one familiar with lantern-slide making, the only requirement other than any lanternist would possess being a special printing frame with aperture for one print only, but length sufficient to move the slide and negative laterally in order to obtain the images in their correct relative positions.

For viewing the finished stereogram the American form of prism stereoscope is good and very cheap, but unquestionably the best effect is obtained in a stereoscope fitted with a pair of achromatic lenses. Mounting and choice of mount used must always remain largely a question of taste. The mount chosen should always be subservient to the print, and the glazed yellow abominations so much in vogue will altogether destroy the beauty of any stereoscopic print. Further, the surface of glazed mounts is easily damaged, and mountant will get into the wrong place somehow. I prefer a Bristol-surfaced mount, off which can be sponged without damage any trace of matter in the wrong place, and I usually use a rich brown, which harmonises particularly well with chloride tones. If a space of about one-eighth of an inch is left between the prints when mounting, a framed effect will be obtained when viewed in the stereoscope, and the same effect is obtained by the use of cut-out mounts. It must not be forgotten, however, that, if the desired width of centres is not to be interfered with, the size of the prints must be slightly reduced to allow for the one-eighth of an inch or so taken up by the division between the two openings of the cut-out. The question of developing and toning hardly comes within the province of this paper, as, with the sole proviso that the density of the negatives should invariably be kept well under, especially if intended for chloride printing, to avoid the snowiness previously commented upon, there is practically nothing that requires any departure from the ordinary every-day practice of photography.

J. E. HODD.

## THE CHROMO CAMERA.

*[Scientific American.]*

THE chromo camera is the name given to a new apparatus for the study of colours and coloured lights. It consists of a cardboard box measuring  $6 \times 6 \times 3\frac{1}{2}$  inches, and open at one end. The box or camera is lined with black cloth, and the interior is lined with dead-back paper. A cover, also black, closes the open end. On one side is an opening  $3\frac{1}{2} \times 1\frac{1}{2}$  inches, the lower edge of the opening being 1 inch from the bottom of the box. With the box are three "tinters," such as are used in colour-projection lanterns. These tinters are made by enclosing a film of coloured gelatine between two lantern-slide covers. A slide mat is placed over the film between the glass covers, and the whole is bound with paper on the edges. One of the tinters is a deep orange-red, one is a yellowish green, and the other is light violet; these three tints in a colour-projection lantern giving a white light on the screen. There should also be with the camera a number of squares of coloured papers, such as are sold in packages of assorted colours for use in kindergartens, some coloured fabrics, ribbons, &c., natural or artificial flowers, and a sheet of stiff white cardboard  $5\frac{1}{2} \times 6$  inches.

The chromo camera is the invention of Mr. Charles Barnard, of New York, and was first used by him in his school lectures on the study of sense impressions of colour. The colour camera is used to examine the colours of objects placed in a coloured light, and to enable the student to mingle diffused white light and a coloured light in various proportions. The invention is here described for the first time, and is freely dedicated by the author to the use of students and teachers.

To use the colour camera, place a table close to a window having a north or sky light, free from reflections from buildings or trees, and cover the table with black cloth or paper. Remove the cover from the box, and place it on the table with the opening uppermost, and with

the open end away from the light. The side curtains should be drawn together to mask the light from the eyes, leaving only a space in the centre a little wider than the box. Draw the shade down to about on the line of the eyes when seated behind the table. Two or three persons can sit at the table, where they can see the interior of the box. The teacher or operator should stand at one side of the table behind the curtains. Here the tinters, coloured papers, &c., are in easy reach.

The box is now fully illuminated by the light that falls through the opening and by the reflected light that enters the open end. Place a sheet of red paper in the box. It is plainly visible. Now lay a book over the opening in the box. The red paper now appears to be almost black in the dark box.

Remove the book and paper, and place the red tint on top of the camera near the back. Slide it slowly forward towards the light, and let the student watch the interior of the camera. When the glass fits the frame and covers the opening, the interior of the camera appears to be a very dark red, the colour being faintly visible near the edge of the opening at the back, and fading away to dead black inside the camera. Place a sheet of white paper in the camera, and it appears a bright pink. The fingers are rosy, and a white flower is pale red. The effect will be improved by placing the cover of the box on edge just above the opening. Remove the red tint, and the paper is again white. Place the green tint over the opening, and the paper is a pale grass-green. Place the violet tint on the box, and the paper is violet.

What has been accomplished? The light contains all colours. The tinters act as strainers. They shut off or strain out all colours except one. The paper capable of reflecting all colours (white) finds only one, and therefore reflects that one and no other. It would reflect it perfectly were it not for the fact that some white light is reflected into the back of the box and mingles with the coloured light. It is this that causes the paper to appear pink under the red tint.

Remove the white paper, and put the red tint in place. Put a red paper or red flower in the camera. It appears a deeper red. Now remove

the cover from the top of the box, and let the operator hold the sheet of white cardboard upright on the edge of the box. Now gently tip it forward, and at the same time move it backward. It acts as a reflector, and throws more white light into the box, and the red flower changes its shade of red, becoming lighter in shade as more white light mingles with the coloured light.

Remove the flower, and place a sheet of pale yellow paper in the camera. It is now a deep golden orange, and, by the aid of the reflector, the colour can be made to change from yellow to orange. The same effect can be produced by sliding the tint back to allow a thin sheet of light to enter the opening. Remove the yellow paper, and place a sheet of green paper in the camera. It appears neither red nor green, but yellow. The eye is now receiving two sensations, a sensation of red from the red light in the camera, and a sensation of green from the green paper partly illuminated by white light that contains green. The compound sensation we call yellow. By sliding the tint backward, or using the reflector, paper can be made to pass from green to yellow through many beautiful tints and shades. Place a white rose in the box, and we shall see a pink rose with yellow leaves. Place a blue flower or blue paper in the camera, and we shall see a purple flower or paper.

Put the green tint on the camera. Now yellow paper is olive green, blue paper is Nile green, bright red paper is dark brown. A red rose is almost black-brown, while its leaves are a vivid green. Slide the tint forward and back to observe the colour change. Try the violet tint, and under its violet light every colour will suffer endless changes as the proportion of white light is allowed to mingle, by means of the reflector, with the coloured light.

These experiments, novel and beautiful as they are, can be greatly improved by using the colour camera in full sunshine. Place the table close to a sunny window in the full sunlight, the best time being between twelve and three o'clock. Draw the shade down till its shadow just touches the back of the camera. Now the shades of the camera will fall on the black cover of the table, and upon it will be a square of sunlight from the opening in the box, this square of light being partly within the box, according to the position of the sun. By tilting the box up at the back it can be thrown inside the box; but, if the curtains are closely drawn, and the other windows are darkened, the effects can all be seen on the table outside the box.

Now all the experiments can be repeated with the most brilliant results. With the red tint, a sheet of blue paper appears a wonderful purple, green is a splendid gold colour, and yellow a red orange. Every colour, single or compound, will appear in marvellous brilliancy, and the students will be lost in wonder at the endless combinations of tint and shade of flowers, paper, and other materials, under the magic of two lights, white light and a coloured light.

Take a piece of cardboard and cut in it a small cross, star, or other figure. Lay this over the red tint, and in the camera we shall see the figure in vivid red on a black ground. Place a green paper in the camera, and the figure seems to shine with an orange-yellow light. Try each tint in the full sunshine, and a great variety of beautiful effects will be observed.

Next take the colour camera to a good north light. Place a sheet of white paper on the bottom of the box, and upon this lay a penknife, rule, pencil, or other small object. Put the object about an inch from the front of the box. The light that falls into the open box causes the object to cast a shadow on the white paper. Now place the violet tint in top of the box, next to the front. Now let the operator move the tint slowly backward till it covers the opening, while the students fix the attention upon the shadow in the box. When the opening begins to be closed by the tint, the shadows deepen. A faint violet fringe appears on the edge. This grows deeper and deeper as the violet twilight in the box decreases. Suddenly another colour appears. The shadow suggests yellow, and just as the tint closes the opening the grey shadow turns to a pale ghost-like yellow. By using the reflector the shadow can be made to turn from grey to yellow at will. With the red tint the shadows are green, with the green tint they are red; in each case the shadow is of the complementary colour of the tint.

Students and teachers will find the chromo camera both useful and entertaining in the study of colour. Such experiments tend to train the eye to a finer appreciation of the distinctions of colour, hue, and shade, and such training cannot fail to add to our enjoyment of nature and art.

## COMPOSITION AND "BREADTH."

In the course of a series of articles on "Points in a Picture" which he is contributing to the *Morning Herald*, Mr. Seymour Lucas, R.A., remarks that, having grasped the meaning of a picture, the next point we may notice is the composition. The grouping of the persons or things depicted should give an effect of unity or totality to the picture. A great painting should be thoroughly homogeneous. It should be harmonious in its idea, and dominated by a motive. No matter how many figures may be introduced, or how many minor interests may be involved, they should all be focussed together by the leading idea. In one word, a picture should be "broad." The word, it may be, as applied

to art, partakes of the nature of slang, though the expression is Biblical. Strictly speaking, it refers to the prominence given to the main idea of the work, and the due subordination of the inferior thoughts and accessories. The recent ornamentation in St. Paul's Cathedral destroys, in the opinion of some, the grand breadth of Wren's work. To express a great thought clearly, and with due regard to its weight, you must not intrude smaller and more vulgar ones. The opposite of breadth is flinching attention to trivial additions and prettinesses.

The decline in the great art of Italy in the seventeenth century is nowhere more plainly apparent than in this respect. The effect of what might be a fine group representing, let us say, the Holy Family, is entirely marred by the gratuitous introduction of a child teasing a cat, or something equally silly and out of keeping with the thoughts that such a subject ought to inspire. An artist must know how to suppress as well as how to give prominence. It may be quite possible to have a picture, well composed as regards outline, broken up and presenting a distracting and irritating effect upon the vision, by excess of emphasis in parts which ought to be more lightly touched.

What good painters we all should be if we only knew when to leave out detail! The overcrowding of a picture is a fault too often committed by the best of us. By the judicious suppression of detail value will be added to a subject as effectively as by strength or softness of shade and light. The earliest and crudest examples of art lack breadth because they show the same elaborate care and finish in all parts of the subject. All the figures are on the same plane, all are finished with the same degree of elaboration and care. Nothing is more striking than this feature in the painting of artists in the early schools of the Renaissance; and its defect is obvious. The eye is distracted, not knowing where to rest, it wanders vaguely over the whole composition and derives no assistance from the skill of the painter. Like the man who bought a dictionary to read as light literature, the spectator never seems to get to the plot. The modern reaction from this is to be found in the work of what is known as the impressionist school. And it must be acknowledged that, in so far as the exponents of this school have emphasised the defect, they have done good service. The danger of impressionism, as it seems to me, is the tendency to exaggerate subordination, and to leave too much to suggestion.

"Please will you tell me," asked a child at a wax-work exhibition, "which is Daniel and which is the lion?" "Whichever you like, my dear," replied the showman; "you pay your money and take your choice." So it is with impressionism. "What is the exact sentiment of that *Nosturne*?" inquires the fair beholder. "Madame, you buy the picture, and interpret it to your liking," is the answer of the obliging dealer.

Nor does it always follow that great breadth is obtained by this vagueness. As Macaulay pointed out, the definite, clear-cut descriptions of Dante's *Inferno* are as powerful and broad as the shadowy, vague, and terrible suggestions in the *Paradise Lost*. We will venture to say that the works of the Dutch painters, or of Meissonier, with their wealth and elaborate detail, possess more real breadth than many of the impressionist pictures. If one were to magnify Meissonier's pictures until his figures assumed the proportions of life, you would still find them to be broad and masterly in appearance. But this quality is, as a rule, very rare in miniature painters. The tendency is to over-elaborate, and become photographic. It is much more common to detect skill in the suggestion of duly subordinated detail in the painters of big pictures. There are, for instance, more large pictures which we could reduce to miniature size without losing subtlety than small pictures which we could enlarge to the proportions of life without destroying breadth.

Great breadth by no means implies baldness. Look, for instance, at Turner's *Chain of the Alps from Grenoble to Chamberi*. Here you get breadth with a tremendous feeling of space—acres of vineyards, gardens, and trees, not to mention the small town or village in the middle distance.

#### PHOTOGRAPHY IN THE TROPICS.

To the June number of the *Camera Club Journal*, Mr. J. O. Neumann contributes the following useful notes on photography in the Tropics. Some of our readers may find them of assistance:—

"*Outfit*.—I found Imperial Sovereign plates answer capitally. Each packet should be packed in a soldered tin. The plates should be backed. Leather should be avoided, as the dampness spoils it, insects and other creatures eat it. The camera should contain only polished wood and brasswork or metal; the latter must be kept well greased with oil or vaseline.

Avoid indiarubber, it gets 'tired' and useless very quickly. No printing paper will stand the climate, so take chemicals and make your own—ferro-prussiate paper for preference. Pack all outfit in a black tin trunk with an overlapping, well-fitting lid, and secure it with a chain and letter-lock in addition to the ordinary lock. Take plenty of permanganate of potassium. Provide yourself with porcelain trays; glass breaks too easily, and others will warp and split at the edges.

"*Exposures*.—I found that the shortest possible exposures between mid-day and two p.m. gave excellent results. Until ten a.m., and often

later, the exhalation of humidity from the soil, caused by the nightly rains, will render photographic attempts more or less precarious.

"*Developing*.—This can only be done at night, and in a part of the house opposite to the one on which the moon is shining. Solutions must be made fresh each day. It is troublesome to make them at night on account of the insects which are attracted by the light, and which come around you in hundreds; it is therefore advisable to make them by day, and at night to place the trays on a few lumps of ice, or place the bottles of solutions in a basin containing the ice; the latter must not on any account be put into the solutions. See that there is a good current of air coming into the room, as it prevents frilling. A good plan is to stand the ruby lamp inside a lantern. I always place water in the bottom of the ruby lamp.

"*Printing*.—Wash your trunk above alluded to well inside and out with a solution of permanganate of potassium, make your ferro-prussiate paper, place it inside the box to dry, and cover the whole with a couple of rugs or blankets. Cut up the paper at night and place it between the leaves of a book ready for use in the morning. The paper prints quickly enough on the Equator.

"*Negatives*.—Clean out the boxes in which they come, and see that there are no traces of insects' eggs. Place a little camphor in muslin at the bottom, replace the negatives, paste all over with cloth or paper, and saturate this covering with strong arsenic solution.

"There are three things one must always encounter and guard against in the Tropics, viz.:—

- "(1) Excessive dampness;
- "(2) Excessive light and absence of light-tight buildings; and
- "(3) Insects.

"The dampness pervades everything, and combined with heat and light makes a formidable enemy.

"No one who has not been to the Tropics has any idea of the number and variety of insects which are to be met with in this world of ours, nor of their propensity to get into the tightest corners, there to propagate their species, which in turn will devour films, &c.

"Take some black paint and paint the inside of your camera every month, and test for holes."

#### FLOWER AND FRUIT PHOTOGRAPHY.

An Exhibition of photographs of fruit, flowers, and allied subjects will be held in connexion with the Autumn Flower Show at Glasgow in September. Silver and bronze medals are offered in a number of classes. Schedule and entry form may now be had from Mr. John Coats, 160, Hope-street, Glasgow. The Judges are Messrs. D. Dewar, John Stuart, and A. Watson.

The following are the conditions and classes:

##### CONDITIONS.

1. Six different pictures to be entered in each class, except as stated.
2. Pictures to be mounted on stiff mounts, but need not be framed.
3. Either direct prints or enlargements may be sent, and any printing process may be employed.
4. Every reasonable care will be taken of exhibits, but the Society will not be responsible for loss or damage.
5. One silver and one bronze medal will be placed at the disposal of the Judges in each class, from 1 to 5.
- Both negatives and prints must be entirely the work of the exhibitor.
6. Each picture must bear on the back of the mount or frame, title of picture and process.
7. The decision of the Judges shall be final. Pictures will be received, carriage paid, at St. Andrew's Hall, Berkeley-street, between 8 and 9 p.m., September 2, from ten o'clock, till Tuesday, September 5, at eight p.m.
8. If to be returned by parcel-post, stamps must be enclosed in a letter addressed to the Secretary.
9. Exhibitors restricted to one entry only in each class.

N.B.—Entries must be sent to the Secretary not later than August 31. No entrance fee will be charged, but exhibitors are not entitled to free admission to the Exhibition.

##### CLASSES.

1. Arrangement of Cut Flowers.—Cut flowers arranged for decoration in vases, jars, baskets, &c.; also bouquets.
2. Indoor Plants.—Specimen plants (or groups of plants) in conservatory or room.
3. Fruits.—Fruit on the tree, or arranged in dishes.
4. Picturesque Spots.—Views in ferneries, rockeries, conservatories, bits in gardens, borders, climbing plants on walls and arbours, specimen shrubs, trees or herbaceous.
5. Landscape Gardening (three pictures only).—Views in parks, large gardens and wooded estates, ornamental waters, &c.
6. Special prizes of 3l., 2l., and 1l., offered by Messrs. Lizars, of 101 and 107, Buchanan-street, Glasgow, for one set of six photographs taken by exhibitor with the firm's 'challenge camera.
- N.B.—Competitors entering for Class 6 must send separate prints, which may be duplicated in previous classes.

## PRACTICAL NOTES ON SOME IRON PRINTING PROCESSES.

## PART V.—SOME LITTLE-KNOWN PROCESSES.

## FERROCYANIC PROCESS OF OBERNETTER.

This process dates back to about the year 1865. Paper is coated by floating on the following bath:—

Hydrochloric acid .....	1 part.
Ferric chloride solution (sp. gr. 1.5) ..	1 "
Copper chloride (crystals) .....	10 parts.
Water .....	100 "

Exposure is given long enough to show a faint image. The paper is then to be removed at once, and floated on the following developing bath:—

Potassium sulphocyanide.....	10 parts.
Sulphuric acid .....	1 part.
Water .....	1000 parts.

To this is added 15 parts of the mixture used for floating and sensitising the paper.

The theory of the process is somewhat as follows: Light reduces the ferric chloride to ferrous chloride. When immersed in the developer, insoluble copper (sulphocyanide) is deposited on the parts converted into ferrous chloride. If, however, the undeveloped print is exposed to moist air, the ferrous chloride reverts to ferric chloride, and the image is lost. Hence the need for prompt development.

Developing at first should be by floating, but when the image is well out, the paper then may profitably be immersed. After development the print must be well washed. It may then be toned, thus:—

*For Red Tones.*—Immerse in a ten per cent. solution of potassium ferricyanide.

*For Purple Tones.*—

Ferric chloride .....	1 part.
Hydrochloric acid .....	2 parts.
Ferrous sulphate .....	2 to 2½ "
Water .....	10, 50 "

The last-named bath will give a range of tones from red through violet and purple to green-black, according to strength of bath and duration of immersion. A final washing in slightly acidulated water completes the process.

## INK PROCESS OF POITEVIN.

This process depends upon the fact that ferric chloride renders gelatine insoluble, but ferrous chloride has not that effect, and that light converts ferric into ferrous chloride. Hence, if paper be coated with gelatine and ferric chloride, printed under a negative, and then placed in warm water, those parts acted on by light (i.e., the shadows of the picture) are converted from ferric to ferrous salt, and the gelatine is soluble. Thus, if the gelatine contains a pigment, we get a negative print from a negative. Hence the process is usable for copying tracings, &c., yielding a positive from a positive direct.

*Ink Process.*—Poitevin's Pigment Process.—

1. Iron perchloride .....	3 parts.
Citric acid.....	2 "
Water .....	100 "

Float the paper for two or three minutes; dry quickly in the dark. Print under a positive. Develop by immersing in a weak solution of glycerine, containing Indian ink in solution. The ink will only affect the parts protected from light by the positive.

2. Dissolve one ounce of gelatine in 15 ounces of water, and add 100 grains of Indian ink, and mix very thoroughly. Float the paper upon this mixture while warm for three minutes. Dry quickly. Sensitise in the following bath by immersing until the paper is limp:—

Tartaric acid .....	7 parts.
Iron perchloride .....	24 "
Water .....	240 "

Dry again quickly in the dark. Print under a positive and develop by immersing in warm water.

## AMMONIO-FERRIC-OXALATE PROCESS.

Paper is coated by floating or brushing with

Ammonio-ferric oxalate .....	1 part,
Water .....	8 parts,

quickly dried in the dark. It will keep good many months. It is exposed until a very faint image is seen, then developed by brushing over with a five per cent. solution of potassium ferricyanide, washed and dried.

*Ammonio-ferric oxalate* may be prepared in the following way: To 5 ounces of water add slowly 3 drachms of sulphuric acid, then add 5 ounces of ferrous sulphate in powder and dissolve by gentle heat. Now add 2 drachms of nitric acid diluted with 1 ounce of water. Boil gently, until the mixture turns red; set aside to cool and add ammonia until a

precipitate ceases to form. The precipitate is iron peroxide. This is now collected and washed once or twice with boiling water and kept in a wide-mouth bottle in a moist pasty state.

Ammonium oxalate must now be prepared:—

Make a saturated solution of oxalic acid, and add ammonia until the solution is neutral. Evaporate and collect the crystals (am. oxalate).

Lastly, take of

Ammonium oxalate.....	437 grains.
Oxalic acid .....	886 "
Water.....	6 ounces.

Dissolve by gentle heat nearly to boiling and add iron peroxide to saturation.

Evaporate to crystallising point and collect the green crystals, and store in the dark.

## IRON-CITRO-OXALATE PROCESS.

The following method has been suggested as a simple way of obtaining prints from a negative.

Prepare the following solutions:—

A.	
Silver nitrate .....	25 grains.
Water .....	1 ounce.
B.	
Iron citrate.....	45 grains.
Iron oxalate .....	25 "
Water .....	1 ounce.

Mix A and B, and permit any precipitate to subside. Coat paper by brushing with the supernatant clear fluid. Dry in the dark, expose under a varnished negative, and wash in running water, giving a final wash in a bath containing one per cent. of ammonia.

REV. F. C. LAMBERT.

## THE SESSION'S WORK OF THE PRACTICAL SECTION OF THE EDINBURGH PHOTOGRAPHIC SOCIETY.

(From the Society's Transactions.)

In dealing with the session's work, I have thought it advisable to run over briefly the principal points connected with the various subjects which have come under our notice.

The camera itself first demanded attention, the popular sizes of which are quarter-plate, half-plate, and whole-plate, the average focal lengths of lenses necessary being 6 inches, 8 inches, and 10 inches respectively, lenses of 10 inches for cabinet and 12 inches for whole-plate being preferred for general work.

The focal length of a lens is the distance from the single lens (or approximately from the diaphragm in the double lens) at which a distant object is focussed on the ground glass, and the diameter of a lens, known as its full aperture, is numbered proportionately to this focal length. The full aperture of a lens of 16-inch focus and a diameter of 2 inches is f-8. The full aperture of a lens may not give the objects in all the different planes in focus at the same time, i.e., when the foreground is sharp, the middle distance and distance will be out of focus, and metal plates or other contrivances are inserted in the lens to make the working aperture smaller. This has the property of rendering in focus or sharp a greater number of planes, but decreases the light in proportion. These metal plates are known as stops, and are numbered in the proportion which their diameter bears to the focal length of the lens. F-8 is one-eighth part of the focal length of the lens, and is 1 inch in diameter in a lens of 8-inch focus, and 2 inches in a lens of 16-inch focus.

The size of a picture at a given distance is proportionate to the focal length of the lens. If we have a certain picture on a quarter-plate with a 6-inch lens, we will have the same picture on a whole-plate with a 12-inch lens, the whole-plate being exactly double the linear measurement of the quarter-plate (4½ inches and 8½ inches). The depth of focus at the centre of all lenses of the same focal length is the same, and depth all over is decided by the covering power of the lens, i.e., the ability to render sharp all the objects in the one plane. Covering power may be said to include both width of angle and flatness of field. The term flatness of field only might be used. The depth of lenses decreases with the increase of focal length, hence the necessity of employing short-focus lenses for speed work in snap-shot photography; but long-focus lenses of the same quality have greater covering power, and, if the covering power of a short focus lens is deficient, an equally good result may be obtained by employing the longer lens and using a larger stop (i.e., a stop of the same number). A truer perspective is obtained by using the longer-focus lens, and, as the depth at the centre of a lens is generally greater than is required, the employment of a larger stop does not interfere with the focus.

Summarising the foregoing, we find that—

1. All stops are numbered, and admit light proportional to the focal length of the lens.

2. All stops of the same number require the same exposure with all lenses for a similar picture.

3. The relative exposure of stops is as the square of their numbers. If  $f\cdot4$  requires 1 second,  $f\cdot8$  will require 4 seconds, and  $f\cdot16$  16 seconds.

4. Long-focus lenses are slower than short-focus lenses, because they require a smaller designation of stop to give the same depth of focus (approximately a stop of one diameter will give the same general definition with all lenses of the same quality).

Let us apply this, disregarding the increase of exposure necessary for increase in the breadth of the shadow in larger pictures, which factor is the only one to be taken into account when photographing all sizes with one lens.

Suppose we take our quarter-plate view with a 6-inch lens and  $f\cdot12$ , giving one second. We will require to use a 12-inch lens to obtain a whole-plate from the same point, and  $f\cdot24$  to give the approximate general focus, and our exposure will be four times as long. With a  $15 \times 12$  camera and 22-inch lens and  $f\cdot44$ , the exposure would be 14 seconds.

To come now to plates. This exposure of 14 seconds is seen to be too long for practical work. We may use a quicker plate and cut it down considerably, and I have found that it is possible to use much quicker plates, and still get the best possible result, for outside large work, than we would require for cabinet work. This is probably owing to the fact that, the correct exposure being relatively longer, the latitude is greater. Plates are of three different speeds—slow, from 40 H. & D. downwards, medium from 80, and rapid anything higher. Some makers number their plates with double these speed numbers, apologising for this by recommending a certain rapid developer. This is unfortunate, but a little studying of the numbers will let us know when the higher numbering is used. With a box marked special rapid 160, it is always safe to assume that the number is 80 in relation to other makes.

The features of slow plates are great latitude, rather, however, on the side of over-exposure, and a tendency to harden quickly, necessitating treatment early in development. Use for landscape work and copying medium plates, good latitude, rather softer, but producing plucky negatives. Use for dark landscape work, slow hand-camera work and seascape hand-camera work. It is essential that the quality of these plates be ascertained, as it is in this variety particularly that there is a tendency to *starve* the emulsion, giving thin, flat results.

The general rule in exposure is to expose for the shadows. Seascapes, open landscapes, or views taken from a height, where the light is necessarily top-light, all require very short exposures. The introduction of a rock or part of the shore in a seascape will lengthen the exposure considerably, the rock now constituting the shadow, giving the relief which was before obtained only by the hollows of the waves and sky shadows. Over or under-exposure in the finished picture is greatly a matter of appearance, and depends on the intensity or breadth of the shadow. A dark engraving will probably require three times the exposure of a light pencil drawing, not because we wish to represent the engraving as if it were a pencil drawing, but simply to meet the requirements of the case. One hundred lines drawn on a sheet of paper require a certain exposure; draw these lines together into ten broad lines, and the exposure necessary will have increased considerably. Therefore expose for the shadows. Inland subjects, especially landscapes in which there is heavy foliage, require very long exposures, owing to the heavy shadows and the fact that green is a very non-actinic colour. For such subjects isochromatic plates, used with a very light screen, will give much softer results and better gradation than is obtainable with an ordinary plate.

With regard to development, two or three points may be noticed. As the behaviour of all developers within certain limits is the same. We will take one (pyro ammonia) as our typical developer, referring, when necessary, to the special features of other developers.

The constituents of the pyro-ammonia developer are—

*Agents.*—Pyrogallol acid, ammonium bromide, sulphite of soda, and water, alkali (or accelerator), liquid ammonia and water.

Some formulae give the bromide in the accelerator, but I cannot see its value when so used, even when using the ammonia developer, and in combination with any other alkali it simply retards the special use of the alkali in under-exposure. An increase of pyro gives density. An increase of bromide retards the shadows. An increase of pyro and bromide gives strong contrasts, but requires a longer exposure. This developer is, therefore, useful for over-exposure. An increase of alkali flattens. An increase of ammonia, however, towards the end of the development does flatten, but simply hastens development, owing principally to the evaporation of ammonia from the developer. Weakening the developer, or putting the plates into water, retards the lights and allows half-tones to gain in strength.

Suppose we have three plates to develop. We commence with a developer slightly weak in alkali. We find one plate under-exposed, one correctly exposed, and one over. Put under-exposed plate into a dish of water, over-exposed one into pyro-bromide solution, make up developer to normal strength, and finish correctly exposed plate. If very slightly under-exposed, the water will very probably have given the necessary flattening to negative number two, and it may be finished in the normal developer. If not, ammonia may be added till the result required is obtained, or a new developer made up without any bromide in very stubborn cases. The use of water, however, in under-exposure is not sufficiently realised. It is advisable also, when "treating" negatives, to rinse the negative in water, in order to remove the developer and allow

the altered developer to begin its work *at once*. With regard to negative number three, pyro does not develop, but it preserves the image, and allows the bromide to do its work. (The negative may be left for a considerable time in this solution if necessary). Ammonia should be added sparingly till the image shows signs of development and the negative finished.

Small brown stains, caused by air bells, &c., on the negative while in the hypo solution may be removed by flowing the negative with sulphuric acid one in forty water.

Green fog may be removed by reducing solution, consisting of ferri-cyanide of potassium and hypo, and the negative may be also reduced by the same. Persulphate of ammonia is, however, preferable as a reducer for hard or chalky negatives, a feature of this reducer being the removal of density in the lights without eating out the details of the shadows. Intensification by mercury or staining by nitrate of uranium will increase the density.

Our attention was next called to hand-camera work. In studying lenses, we said that depth of focus at the centre depended entirely on the focal length of a lens and the size of its aperture, and that it decreased with the increase of focal length. If we have a 5-inch and a 7-inch lens, both of which give the necessary covering power, which, then, shall we use? If we wish correct perspective, use the longer lens; but, in so doing, we must sacrifice speed, as  $f\cdot8$  must be used with the 7-inch lens to give us the same depth as we get with  $f\cdot6$  in the 5-inch lens, and our exposure will be double the length. The question of depth, however, has become of late years a disputed question, very few of our workers inclining to ultra sharpness, and many preferring that the photograph should be sharp only in a single plane. This applies to photography generally, and, while our opticians are striving to produce a perfect lens, many of our best workers are doing their best work with the old spectacle or monocular lens.

Find out first what result you wish, and then work for it.

Focus in a single plane may be got by using a long-focus lens, or one with a very flat field, a large stop being used.

To obtain focus in the centre of picture only, use short-focus or round lens and large stop.

Diffusion all over is best obtained by focussing far forward, that is, with a greater distance between lens and ground glass than is required even for the foreground, and employing a small stop, or by employing a single "uncorrected" lens. The results, however, should be aimed at only when the elementary principles of photography are mastered. Afterwards, variety of result is more a matter of individual taste and thought than of fixed rule, and the method of obtaining such will generally suggest itself.

To return to hand-camera work, however. The usual lenses employed in hand-camera work are 5-inch for quarter-plate and  $7\frac{1}{2}$ -inch for half-plate, but slightly longer-focus lenses are desirable if great speed is not required. One-thirtieth of a second with  $f\cdot8$  on an 80 speed plate will give us an easily developable result with most subjects,  $\frac{1}{100}$  second may be taken as the arrested motion speed, and nothing less than  $\frac{1}{100}$  for subjects actually moving, unless very far away, using, of course, the fastest speed plates. In developing snap-shot photographs, an error is often made in assuming that they are very much under-exposed, and when correctly exposed plates are so developed a flat image is the result. Many of our snap-shot subjects, too, are those on which there is plenty of light, and the result to be aimed at is the acquiring of contrast, and not the registration of detail, of which there is a superabundance. With a plate which does not readily fog, a weakened developer, *i.e.*, a developer weakened with water, is safe for any hand-camera subject, finishing in this developer if found to be under-exposed, and strengthening in case of correct or over-exposure. If under-exposure is absolutely certain, the new developers—amidol, metol, rodinal—may be used, their general tendency being to flash up detail first and give density afterwards.

The method of varnishing the plate is to slightly heat before the fire and, holding the plate level, pour over it negative varnish till it forms a pool covering one-third of the plate; tip the varnish away from the corner held in the hand, then along the top, down the left-hand side, along the lower edge, and then drain into bottle at the right lower corner. Dry with the film side next the fire.

The printing processes are multifarious, but the chief and long-tried form themselves into three distinct groups—silver, carbon, platinum. The chief silver processes are gelatino-chloride and collodio-chloride, and for these processes, as regards present quality, the combined-bath gives the best result. A slight washing should precede the toning and fixing processes, and an extra fixing bath should be used. The preliminary washing ensures purity in the whites, and the extra fixing bath guarantees permanency, in so far as permanency can be got with this process, but neither in theory nor in practice can gelatino-chloride paper be looked upon as permanent. With care, however, prints in this process will last much longer than is generally supposed. For those who prefer a separate bath, I find that the borax bath or chloride of lime bath gives the best results. Sulphocyanide of ammonium results are too cold. It is still an open question as to whether either of these processes are better than the albumenised paper silver process, which they have replaced, but at present they are more popular.

The theory of carbon printing, which got its name from the fact that carbon was the first pigment used in the manufacture of this paper, is the non-solubility in hot water of bichromatised gelatine when affected by light, and its solubility when not so affected. A piece of paper is floated over a solution of gelatine, with which is intermixed a pigment or colour of some sort, and, when dry, it is immersed in bichromate of potassium solution. This, on being acted on by light through a negative, becomes insoluble in proportion to the amount of light which it has received. The fact that the image is on the front of the paper necessitates the washing away of the soluble gelatine from the back, and the print is for this purpose transferred to a temporary support, the procedure being to allow the print to lie in water till moist, and then squeeze the surfaces together. It is developed on this support by being treated with hot water and then alumed, being finally transferred to its permanent support and allowed to dry. This is known as the double transfer process, and an alternative method is to reverse the negative, in which case only one transfer is necessary, this being distinguished as single transfer. It may be remarked that the word insoluble is comparative. Only very hot water will dissolve out all the soluble compound, so that by employing water of various degrees of temperature we have a certain latitude of exposure. We can also have any surface according to the support which we use, a uniformity of colour which is not approached by any other process, and can rely on its permanency. One of the chief elements of success is in drying the paper after sensitising. It must dry regularly and not become dry and damp alternately, and time should be allowed for the image to adhere to its various supports. Attention should also be given to allow the final support to be quite limp before being squeezed on to picture.

In platinum printing, if plucky results are required, it is absolutely necessary to keep the paper dry. The oxalate bath gives excellent results when the paper is in good condition, but does not allow of much latitude in keeping. The D or developing salts of the company gives slightly pluckier results, the blacks being stronger, and the whole print a little colder. I prefer this bath to the oxalate. These baths are best used at a temperature of 60°, but can be used quite hot if warmer results are required.

A bath of oxalate, to which phosphate and sulphate of potash has been added, or the addition of phosphate to D salts, is said to give black-and-white results, and to be therefore useful for weak negatives. This addition is only effectual, however, when the paper is in very good condition. Printing dark and stopping development before quite complete will give a similar result.

The sepia paper is obtained by the addition of mercury to the platinum salt of the paper, and is developed in a warm bath, with the addition of a special solution of the company. The hotter the bath, the warmer the tone, and, if a still warmer tone is desired, it may be obtained by exposing the paper to damp before development. These papers are fixed in hydrochloric acid.

With regard to bromide work, little need be said. The exposure in enlargement is as the square of the diameter of the picture. A whole-plate enlargement requires four times the exposure of a quarter-plate from the same negative, with probably a slight increase owing to the increase in the breadth of the shadow—say five times in all for the average picture. An amidol developer will give a blue black, metol a slightly browner black, and hydroquinone may be used in combination with metol, giving more of a dead-black image than either. It is best, at least until experienced, to use the developer recommended by the makers of the paper. Plunge, without washing, into strong hypo, but finish fixing in a weaker solution. The same exposure-rule applies to negative enlarging, a good transparency being almost absolutely essential. This must be full of detail, and possess the quality known as soft (not out of focus).

In interior work, use the longest-focus lens which will give the result required. Keep the camera square and fairly low, use the cross front to obtain dissimilarity if necessary, and the exposure may be anything from two minutes with *f*-16 to five or six hours, the usual being ten or fifteen minutes with *f*-22 on an 80-speed plate. Use backed plates where there are strong lights, and the flash lamp when directly facing the windows.

With regard to the new papers, *velox*, *gravura*, &c., I find them admirably adapted for the purpose for which they are required. The metol developer gives in my hands the best results. Too much bromide should not be used—rather less, I find, than the makers recommend; and the developer should not be used weaker than is recommended, as the blacks tend to deterioration when so developed. Although any colour may be obtained by these papers, I cannot recommend their use for this purpose, carbon being by far the best colour process.

JOHN BANKS.

## BAS-RELIEFS BY A PHOTOGRAPHIC PROCESS.

[Revue Suisse.]

A NEW method of photo-sculpture—which must not, by the way, be confused with the relief photographs obtained by the compression of ordinary photographic prints against a matrix graven by hand—has been just introduced, under the name of *phototérisé*, by M. Lernaie in collaboration, on the practical side of the process, with M. Nadar père.

The medallions obtained are of all dimensions, from coins of the realm up to larger pieces, and in all grades of relief, from a few millimetres up to five or six centimetres, whilst the process is remarkable for its simplicity.

The model, who need not be powdered or painted, is placed in front of a dark background, so that the profile is presented to a photographic camera. Two negatives are taken, avoiding, for obvious reasons, all movement of the model during the short interval between the two exposures. The source of light for these two exposures should be as confined as possible—a magnesium flashlight—and is placed in a plane perpendicular to the axis of the lens, and slightly nearer to the latter than to the model. During one exposure the lighting is about three quarters to the rear of the subject; during the other, about three quarters towards the front. The two negatives are stripped and exactly superimposed one on the other. Their combination then represents in black the salient features of the subject which, in either one pose or the other, have received the maximum of light; the less prominent features, more feebly lighted, are represented in grey; whilst cavities in the face are reproduced as clear glass, owing to the special kind of lighting having kept them in shadow during each exposure. From the composite negative thus obtained a print is taken on any paper which lends itself easily to retouching, say, platinum paper.

On the image, which is visible at this stage, of which the whites correspond to the highest parts in relief of the subject, the operator proceeds to work in, with water colour or Chinese white, the tones which correspond to the degree of relief of the hair, the clothes, and other parts, which, by reason of their rather non-actinic colour, do not lend themselves readily to automatic reproduction in relief; it needs to be borne in mind that the exact reproduction of the relief of a head of hair would be hardly compatible with the usual conventions of sculpture.

At this stage also must be put in—in white or black according as they are to appear in relief or otherwise—the letters or ornaments which are to appear in the exergue. The profile of the medallion or coin is put in at the same time with Chinese ink.

This design in black and white is then reproduced in the form which it is destined eventually to take, and the new negative thus obtained will be used for making proofs in relief destined to serve as moulds. For feeble reliefs the printing is executed by well-known methods on a sheet of bichromated gelatine, but this would not be sufficient to give the relief of five centimetres and over demanded by large pieces of work. For such, a very thin film of gelatine is flowed on to a sheet of spongy material, swelling easily in water. The superficial gelatine film is sensitised with bichromate, and after drying exposed under the negative just described. It is then treated with water, which passing easily through those portions of the film protected from the action of light, and repelled, on the other hand, from those portions exposed, causes a swelling of the image corresponding to the relief of the original model. On to the block thus formed fine plaster is flowed and a plastic material pressed into the crevices, upon which retouching can be done. This last operation completes the relief in which the moulding of the points is executed. It may be added that the total time in retouching the intermediate black-and-white point and the relief in plastic material is about an hour for a medallion of large size.

L. P. CLERC.

## THE GREENWICH VISITATION.

ON Saturday last, June 3, the Board of Visitors visited Greenwich Observatory, for the reception of the Astronomer Royal's annual report. Lord Lister was unable to be present, but his place was taken by Professor G. H. Darwin (President of the Royal Astronomical Society), and among well-known faces were those of Sir G. Stokes, Sir R. Temple, Sir R. Ball, Professor Langley (U.S.A.), Professor Cornu (France), General Brackenbury, Captain Abney, Dr. Glaisher, Rear-Admiral Wharton, the Rev. Brooke Lambert, Sir W. Huggins, the Earl of Rosse, and many others.

The principal feature in the day's proceedings was the presentation to the Board of Visitors of the annual report of the Astronomer Royal. This year Mr. W. H. M. Christie had a good deal that was interesting to impart. He was naturally jubilant over the completion of the new Observatory building, which has been in progress since 1891, by the addition of the east and west wings. This handsome building provides much-needed accommodation for the Observatory staff. It has four wings of three stories, with a central tower carrying the Thompson equatorial and dome. Its completion makes it desirable that the boundary of the Observatory should be enlarged in order to show off the handsome new building. A proposal to give effect to this is under the consideration of the Admiralty, and there should, one would think, be no difficulty in the way. Among other additional buildings is the new magnetic pavilion, at a distance of about 350 yards from the Observatory, on the east side, which was completed at the end of September. The magnetic instruments for absolute determinations have been installed here. The greatest care has been taken to exclude all iron in building the pavilion, and the site has been selected so that there is no suspicion of magnetic disturbance from iron in the neighbourhood. The enclosure also provides a good meteorological station, where the standard thermometers and rain-gauges have been mounted.

During the year the sky has been closely scrutinised, the figures given by Mr. Christie being:—Transits, 11,764; determinations of collimation error, 298; determinations of level error, 694; circle observations, 10,830; determinations of nadir point, 665; reflex observations of stars, 560. The number of stars observed in 1898 was about 5000, and the meridian observations 1200 more than the average of the three preceding years.

As showing the progress made with the photo-mapping of the heavens, Mr. Christie gave a table which showed that, during the year ending May 10, 1027 successful fields were taken for the chart and 1030 for the catalogue, leaving 122 and 119 respectively to be taken of the 122 fields still to be photographed for the chart; 101 are within 7 degrees of the Pole, and this part of the sky was purposely left until near the epoch 1900.

During the same period photographs of the sun have been taken on 195 days, either with the Dallmeyer or Thompson photo-heliographs, and of these 394 have been selected for preservation, besides sixteen with double images of the sun. The chief incident in the history of the sun's surface during the period covered by the report was the very remarkable temporary revival of activity which set in at the end of July, and lasted almost to the middle of November, culminating in the appearance of the great group of spots of September 3 to 15. In the same connexion it may be mentioned that the number of hours of bright sunshine recorded during the twelve months was 1500, out of the 4454 during which the sun was above the horizon.

According to Mr. Christie, the mean temperature of the year 1898 was 51.3 degrees, being 1.8 degrees above the average for the fifty years, 1841-90. The highest daily temperature recorded in the shade was 92.1 degrees, on September 8, a rare occurrence for that month, only equalled once in fifty-seven years. On the other hand there were 158 rainy days, and the rainfall was 22.74 inches, being 1.80 inches less than the average of fifty years. The rainfall in September was the smallest, with one exception, since 1841.

#### AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

At a meeting of delegates, held at 12, Hanover-square, W., on Friday, June 2, Mr. R. Child Bayley in the chair, a report made to the Council of the Royal Photographic Society by the sub-Committee on the relations between the Affiliation and the Society, and referred by the Council to this Committee, was considered, and with it a number of suggestions made by the various societies for the improvement of the scheme. In the discussion which ensued it was thought that the time had come when an improved system of conducting affairs might be initiated, the first step in which might be the appointment of a small executive Committee, to be intrusted with the work of carrying on the business of the Affiliation in the intervals between the general meetings of delegates. The following delegates were appointed the Executive Committee of ten members with the Hon. Secretary and Hon. Treasurer as *ex-officio* members of the same: Messrs. R. Beckett, H. W. Bennett, E. Dockree, S. H. Fry, J. A. Hodges, A. Mackie, J. C. S. Mummery, C. H. Oakden, J. A. Sinclair, and H. S. Ward, the Committee to have power to fill any vacancies. It was agreed to refer to the Committee the matter of the report from the Council of the Royal Photographic Society, together with the question of new lectures and slides for circulation, a number of topics for the former being suggested. It was decided to approach the Earl of Crawford with a view to inducing him to accept the office of Chairman of the Affiliation. A vote of thanks was passed to Mr. Child Bayley for his services as Chairman.

#### PALL MALL EXHIBITION, 1899.

The following is the result of the ballot for the Judges:—

Pictorial Section.	Technical and Scientific Section.
Harold Baker.	Capt. W. de W. Abney.
Colonel J. Gale.	Thomas Bolas.
A. Horsley Hinton.	Chapman Jones.
B. W. Leader, R.A.	
W. L. Wyllie, A.R.A.	

#### THE PRINCE OF WALES AND THE ROYAL INSTITUTION.

At the Centenary Dinner of the Royal Institution, which was held on Monday last, and which was attended by the principal English men of science of the day, the Prince of Wales made the following interesting observations:—

"Though it is nearly half a century ago, I have not forgotten as a boy the Duke of Coburg and myself being sent by our father to London, soon after Christmas, to attend those famous lectures which were then given by the great Professor, Michael Faraday. I have not forgotten the interest which we took in those lectures, and the clear way in which he

explained to the boys the difficult scientific problems, or the beautiful manner in which he showed us the chemical experiments which were then the order of the day. On an occasion of this kind it is very difficult to say anything new regarding an institution of this character, or to say anything that is not known by so distinguished and able an audience as is assembled here to-night; but, when one looks back, one thinks that 100 years ago this Society was just formed by Sir Benjamin Thompson, who was better known—and he himself would like to be better known—by the name of Count Rumford. And what is remarkable is that 100 years ago the same building, though it has perhaps changed in architecture, was purchased by Mr. Mellish, in which the work of the Institution is carried on and the lectures are given at the present day, in Albemarle-street. Of course, this Society has seen many vicissitudes, but fortunately there have been people to assist it in a pecuniary way, and only as recently as three years ago we were indebted to the liberality of Dr. Mond, who gave us, and endowed, the Faraday Laboratory, at the opening of which I myself had the pleasure of being present. When one looks back on all the eminent men who have worked and lectured at this Institution, one thinks first of the name of Thomas Young, and of the great Humphrey Davy—a man of whom all Englishmen are proud, and one of whose most remarkable discoveries, perhaps, was that wonderful lamp, which, philanthropically speaking, has saved the lives of thousands and thousands of miners. Then there is another name to which, in this connexion, I must again refer, that of Professor Michael Faraday, whom it was my privilege to know, and whom I shall ever associate in my mind with your Institution. I should also mention his distinguished successor, Professor Tyndall. At the present day there is a name that every one looks up to—a name remarkable as regards science in its every branch—that of Lord Rayleigh."

On Tuesday afternoon His Royal Highness took the chair on the occasion of the delivery of a commemoration lecture on "Thomas Young," by Lord Rayleigh, who, surrounded by all the apparatus essential to the delivery of an illustrated scientific discourse, explained at once how impossible it would be to deliver in the space of a single afternoon anything like a "commemoration" lecture in the sense of one recalling, even cursorily, the scientific achievements of the great men of science of the past century. No attempt would he make, therefore, to review the work of such men as Young and Davy, Faraday and Tyndall, Frankland and Gladstone; but, taking the discoveries made and developments introduced by Thomas Young as belonging to the scientific achievements of the early part of the century, he proposed presenting a brief retrospect of his researches. Having thus cleared the ground, the learned Professor, with the help of projection apparatus, exhibited some of the most striking of those experiments by which Young had demonstrated the results of his historic investigations. Foremost of these was the wave theory of light. As the great Newton had adopted the corpuscular, or emission, theory, Dr. Young's profoundly important doctrine encountered strenuous and even bitter opposition, especially from Lord Brougham. It was only after its independent discovery and enunciation by Fresnel that the soundness of Young's undulatory principle was admitted, as it now is universally. He was one of the first also to state in accurate language the true conception of energy as measured by the power of matter in motion to do work. The composition of colours, the tides, sound, and heat were among the subjects of his investigation, and he touched nothing that he did not adorn. "Perhaps," said Lord Rayleigh, towards the close of his discourse, "I have left you under the impression that Young knew everything;" and, lest his hearers should indeed carry away such an opinion, he hastened to recall, amid laughter, the brilliant savant's surprising declaration upon one occasion, that "there is no reason to imagine any immediate connexion between electricity and magnetism."

#### SOCIETY OF ARTS CONVERSAZIONE.

The Society's *Conversazione* will take place at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday evening, June 20, from 9 to 12 p.m.

The Reception will be held by Sir John Wolfe Barry, K.C.B., F.R.S., Chairman, and the other members of the Council, from 9 to 10 p.m.

The following portions of the Museum will be open: On the ground floor, the Central Hall, British Saloon, and Bird Gallery; on the first floor, the East and West Corridors.

A selection of music will be performed by the String Band of the Royal Artillery in the Central Hall, and by the Red Hungarian Band in the Bird Gallery, commencing at 9 o'clock.

Light refreshments (tea, coffee, ices, claret cup, &c.) will be supplied.

The entrance to the Museum is in the Cromwell-road. Carriages must enter the grounds by the east gate, and leave by the west gate. The cards must be given up on entering the Museum.

Visitors arriving or leaving by either of the Metropolitan railways will be allowed the use of the District Company's subway, which leads from the South Kensington Railway Station direct into the grounds of the Museum.

Further particulars as to the musical and other arrangements will be given in the programmes, which will be distributed on the evening.

## Our Editorial Table.

ADUROL-HAUFF.

Messrs. FOERST BROS., of 17, Philpot-lane, E.C., inform us that they are agents for this new developer, the principal features of which are as follows: It is the monochloride substitute of hydroquinone in the form of a white crystalline powder, easily soluble in water. The solutions keep for an extraordinarily long time, even in open bottles, and the used developing solution can be utilised again and again until entirely exhausted. It works more rapidly than hydroquinone, and is, even in winter, hardly influenced at all by the temperature. It is claimed to be an energetic, detail-giving, and clear working developer, without being rapid in the proper sense of the word. It gives much more density than hydroquinone, without any tendency to hardness, and is therefore advantageous for snap-shot and studio work and bromide paper. It does not require any clearing bath, and does not stain the fingers or attack the skin.

Mr. C. S. JONES, of High-street, Woodford Green, sends us some samples of what he terms "Photo Seals." These are embossed and coloured discs about three-quarters of an inch in diameter, and coated with an adhesive on the back. On the front tiny portraits of celebrities are printed, or any other photograph may be used. These "Photo Seals" are designed for use on note-paper, envelopes, postcards, visiting cards, wedding cards, invitations, menus, programmes. It is a pretty idea, which will doubtless, commend itself to many.

### THE "LITCHENSTEIN" BACKING.

Manufactured by Lichenstein & Co., Silvertown, E.

Messrs. LITCHENSTEIN, who are well known as manufacturers of caramel, &c., have sent us a sample of their caramel backing for photographic dry plates. It is put up in collapsible tubes, and has the consistency of a thick treacle substance. In this form it is easily applied to the back of the plate, and, as it dries very rapidly, it forms the *beau-idéal* of a backing mixture. Messrs. Lichenstein know perfectly well by experience what is required in a compound of this character, and their backing will be found a carefully prepared mixture, which thoroughly answers the test of practical trial.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, June 14, at eight o'clock. Members' Open Night.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, June 13, at 12, Hanover-square, at eight p.m. "Acetylene," by Professor Vivian B. Lewes.

THE publication in Great Britain of the *Art Amateur* will be resumed next month by Messrs Griffith, Farran, Browne, & Co., who intend to publish the English edition on the 15th of every month.

THE DERBY EXHIBITION.—The following are the awards in the competitive section of this Exhibition, which was opened on Tuesday evening last:—Silver medals: Messrs. H. Burkinshaw, F. C. Smithard, and C. J. Allen. Bronze medals: Mr. G. Walker. Mrs. F. H. Gandy, Miss E. Boden, and Mrs. Highton.

A STATUE to the eminent physicist, Helmholtz, was unveiled on Tuesday in front of the University, Berlin, in the presence of the Emperor and the Crown Prince. Helmholtz's statue is in close proximity to those of the two Humboldts. The occasion was made especially interesting as the first on which the Crown Prince has represented his father at a public function.

CITY AND GUILDS OF LONDON INSTITUTE.—The Exhibition of Practical Work executed by candidates at the Institute's Technological and Manual Training Examinations, 1899, to be held at the Imperial Institute (North Gallery), by permission of the Governing Body, will be opened to-day, Friday, June 9, at 3.30 o'clock precisely, by His Grace the Duke of Devonshire, K.G., Lord President of the Council.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Saturday, June 17, there will be a photographic outing of the members to Westmoor Hall, Brimadon, at the kind invitation of Mr. A. L. Henderson. Will those members who wish to go communicate with the Hon. Secretary, 45, Torrington-avenue, N.W., who has the arrangements in hand? Great Eastern Railway, first train after two o'clock.

Messrs. W. W. ARTHUR, T. S. MUIR, & S. H. FULTON, of 36, West Nile-street, Glasgow, write: "Having acquired the old-established optical business of Messrs. Gardner & Co., it is our intention to add thereto a complete stock of photographic material. Our knowledge of the requirements in photography is a guarantee that nothing will be lacking to make this department a success. The stock will be replete with everything necessary for professional and amateur, and kept thoroughly up to date. Our optical department contains all the newest patterns of spectacles, eyeglasses, field and opera glasses, and general optical goods."

TRANSPARENT wire glass has recently been placed in the market for use in unprotected windows exposed to flames, where shutters are not desired. Wire glass has been recognised for several years as a valuable fire-resisting material, but solid cast glass having wire imbedded in it, which is also sufficiently transparent for use in windows, is believed to be a novelty. A firm in New York has recently succeeded in producing this material in sheets 18x40 inches in size and a quarter-inch and three-eighths of an inch thick. The glass is cast about a wire screen having an inch mesh, and is then polished on both sides to give it the necessary finish for use in windows.

A PARIS PICTURE SALE.—The four days' Valenciennes sale at the Petit Gallery in Paris was followed with much interest. The first day's sale, devoted to pictures and sculptures, realised 421,263fr. The portrait of Christopher Columbus, by Sebastien del Piombo, the only contemporary portrait of the great explorer, fetched 30,000fr. Two portraits of Talleyrand, by Prud'hon, were sold for 25,000fr. and 10,000fr. respectively. The sale included a series of royal portraits presented to Talleyrand by the different sovereigns whom he had served from time to time. One of these, Napoleon I., by Baron Gérard, fetched 16,500fr.; those of Louis XVIII., Charles X., and Frederick Augustus, King of Saxony, going for much less. Busts of Molière and La Fontaine, by Houdon, realised 48,000fr. and 30,000fr. respectively.

THE ST. HELEN'S EXPLOSION.—The inquest on the five victims of the explosion at the chlorate refinery in Karts' Works, one of the large concerns taken over a few years since by the United Alkali Company, was resumed at St. Helen's on Tuesday, May 30. It will be remembered that on May 12 a fire broke out in the crystallising room containing wooden tanks used for cooling chlorate. The flames ran from tank to tank, and quickly enveloped the whole building, the fire also spreading to the roof of a house where 160 tons of chlorate were stored. A little later the chlorate exploded with terrific force just as the workers were hurrying to places of safety, and reduced to ruins the extensive buildings of the firm. The vitriol chamber in the adjoining works was wrecked, a large number of dwellings in the surrounding district were devastated, and nearly all the large plate-glass windows of the town were shattered. Two men were killed on the spot, and twenty others were removed to hospital, three of the latter proving fatal. After all the evidence had been heard, Colonel Ford, Inspector of Explosives, and Mr. Richmond, Factory Inspector, expressed the opinion that chlorate should be stored some distance from manufacturing plant. The jury returned a verdict of "Accidental death," and suggested that buildings for chlorate plant should be fireproof, that the cooling tanks should be of iron instead of wood, and that chlorate should be stored in quantities limited by Government control.

"THE world was ever thus—I verily believe some of the pairs which wandered into the ark strayed there by mistake. Any way, some that have existence to-day 'never would be missed.' 'No, I am not thinking about the lively flea,' says a writer in a *Leamington* contemporary, 'but I wondered if the individuals who bother photographers had extraordinary jumping powers which enabled them to pop into all sorts and conditions of pictures. Take the photograph of the motor cars the other day. I am told a professional gentleman was commissioned to photograph the cars, the members, and the attendants. Would you believe it, there were several local fleas—I mean persons—in the picture. Of course, they popped in the Regent Hotel yard by mistake, and by mistake got in the range of focus just when the photographer deftly removed the cap from the lens, and by mistake they will wander past that photographer's window dozens of times to see if, by mistake, their images appear in the prints exhibited. Alas! by the process known as 'blocking out,' certain forms and objectionable features are obliterated even from photographs, and the picture, although causing additional labour through the springing capacity of the 'always-there' section of the community, appears as ordered, with cars, members, and attendants only. I remember, when the photographs were taken for the current edition of the *Royal Leamington Spa Pictorial*, that a whole host of youngsters got in the range of view when the Pump-room Grounds photograph was being taken, and I was much amused to see the way the children were handled by the photographer's assistant. It was thought desirable to have a few figures in the picture by way of relief, but the children directly the tripod was fixed flocked up in shoals. Having gauged the exact line of the picture, that assistant d-lighted dozens of little boys and girls by asking them to sit down upon the grass and to keep quiet. They were good children, they kept quiet, and by just about a yard saved the photographer the trouble of 'blocking' them out of the negative."

A CINEMATOGRAPH SCARE.—During a representation of the Passion Play at Oberammergau on the West-end Pier, Morecambe, on Sunday afternoon, which was illustrated with lantern and cinematograph views, a stampede took place amongst the audience, on account of the film of the cinematograph igniting. The area of the hall was packed, and, besides, there were a large number of people in the balcony. Everything went well for the first hour, but, when the cinematograph was about to produce the first series of views (the hall, of course, being in entire darkness), the film took fire and blazed up like an electric light. There was at once a wild rush of men and women in the darkness for the doors, and, although a few kept their heads and shouted, "Keep your seats! there is no danger," the panic was on, and confusion reigned until the greater part of the audience managed to make their exit. The orchestra, with great presence of mind, struck up a tune, but order was not restored until every door in the place had been thrown open and the electric lights turned on. The programme was proceeded with before a greatly diminished audience, but every time the cinematograph flared up there was a distinct feeling of nervousness. Fortunately, every one escaped with nothing worse than a severe crushing and a fright. Some zealous person broke the glass of a case outside the hall, where hose pipes are kept for emergencies, but the pipes were not needed. Mr. John Prior, Manager and Secretary of the Company, writes to say that the reports of the cinematograph accident at the performance on Sunday afternoon have been exaggerated. He states that there was only a slight interruption to the pro-

gramme, owing to one of the lantern regulators getting out of order. Immediately this happened the electric light was switched on and every exit door opened. The hall could have been cleared in two minutes, but the majority of the audience had no desire to leave their seats, and very few did so, most of whom immediately returned on the resumption of the performance. A the evening performance the hall was packed.

THE young British artist is a creature of queer moods and impulses. He is generally insufficiently trained. In the beginning he worships a laborious sort of drawing. Towards the end of this period he may be discovered wearing a terra-cotta or sage-green tie. It is a sign that he has discovered colour. The preliminary stages of this disease are painfully distressing to the observer. Occasionally they reveal a distinct phase of colour-blindness, writes Mr. Edward Hill in the *Sunday Sun*, varying in accordance with the prevailing fashion. Some years ago it was generally understood by the elect that all sunlight was "heliotrope." You had to shut your eyes two-thirds to get the effect. Then another school arose—I speak of the students, not of the masters—who invented iridescence, feebly following Monet. This, in the student, was distinctly humorous. Yet another generation specialised in slaty-blue. Once in a way you can veritably find something of this kind in nature—or at all events in Cornwall. Woe betide the youth who lets his senses be entangled in the meshes of "line." For him will Dürer have lived in vain, seeing that he has vended his soul to the curve of the Japanese colour print as interpreted by Beardsley and the "Dial." Long and sinuous will be his females, and the tulips of his wall-papers faint (as for lack of water) and inter-twinning. For him is there no salvation. He will become a designer of his fellows' book plates. Symbolism is another terrible happening to the young in art. It will afflict him at about the same time of life as that when the mere reader of books, becoming amorous, takes to writing verses. Providence, in its mercy, has arranged that the self-critical faculty shall be entirely absent from both classes in these days. It does this to afford comic relief to their elders, who are oppressed with the cares and sterner worries of daily life. I do not decry these young emotions. They are part of the process, and serve well to mark the miles along the road. I was reading some of my own verses the other night. They sent me very happily to bed. But imitation in art is a different matter altogether. It is inconceivable to me that critics can be found to praise some of the baser manifestations of it. That a living man, who has by stress of his soul and work of his hands acquired skill in handicraft, should deliberately set aside all his surroundings and try to project himself some centuries back into another life, is mere treason to his fellow-men. If he entirely succeeds, he may, guiltlessly or otherwise, commit forgery. There was the case of Bastianini. If he fails—as, being honest, he generally does—he rarely has the poor satisfaction of having added even to the world's amusements.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
10.....	Darwen .....	Excursion: Liverpool and New Brighton.
13.....	Birmingham Photo. Society ..	Flower Photography. H. T. Malby, F.R.P.S.
13.....	Hackney .....	Sale and Exchange Night.
13.....	Oldham .....	Excursion: Arley Hall. Leader, W. A. Nash.
13.....	Royal Photographic Society ..	Acetylene. Professor Vivian B. Lewes.
14.....	Photographic Club .....	Members' Open Night.
15.....	London and Provincial .....	Paper by Walter D. Welford.
17.....	Ashton-under-Lyne.....	Excursion: Reddish Vale. Leader, William Turner.
17.....	Birmingham Photo. Society ..	Excursion: Charleotte Hall, near Stratford-on-Avon. Leader, C. J. Fowler.
17.....	Borough Polytechnic.....	Excursion: Perivale and Twyford Abbey. Leader, P. C. Cornford.
17.....	Croydon Microscopical .....	Excursion: Godstone, Tandridge, and Oxted. Leader, Dr. Parsons.
17.....	Hackney .....	Excursion: Molesey. Leader, Major Woolmer-Williams.
17.....	London and Provincial .....	Excursion: Westmoor Hall, Brimsdown.
17.....	Oldham .....	Excursion: Oldham Municipal Jubilee.
18.....	South London .....	Leader, J. Fullalove.
		Sunday Excursion.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 1.—Mr. A. Mackie in the chair.

Mr. R. P. Drage passed round some old 12×10 wet-plate negatives, believed to be the work of Robert Kennett. The good quality of the photographs was the subject of remark, and a desire was expressed to see prints.

Mr. W. T. WILKINSON very much doubted whether the ordinary gelatin-chloride printing-out paper would do the negatives full credit. A natural tendency to brilliancy would be increased to hardness in the result, but it was pointed out, in reply to this, that the extreme depths of the shadows were really much more transparent than the same apparent depth of the present class of negative, and that they would print with more softness than an uninitiated person might imagine.

Mr. J. S. TEAPE passed round some negatives which were, he said, exposed alike for  $\frac{1}{2}$  second at  $f/22$ . They were developed with others, similarly exposed, in a sodinal solution (one in thirty) for three-quarters of an hour, at the end of which time some were positives and some negatives, the change to the positive state occurring in the ten minutes preceding their removal from the developer. This curious occurrence, it was pointed out, took place before fixing, and Mr. Teape had no reason to expect that any light had struck the plate in the interval, which was suggested as a likely cause for the reversal of

the image. The change from negative to positive was most pronounced and not of the more common, but partial, change.

Mr. J. E. HODD read a paper upon

### STEREOSCOPIC PHOTOGRAPHY [See p. 358].

the effect of which, he hoped, would be to expand the ranks of the recruits when he showed how little was the trouble and difficulty in this, one of the most fascinating of processes. Laid upon the table were a large number of stereoscopic prints from his own and his brother's negatives, with an example of the work of Mr. Victor Selb, of Antwerp. Incidentally, the lecturer stated that fourteen of the prints, equal to twenty-eight of quarter-plate size, were toned with no more than half a grain of gold, the paper being Special Sylvio, intended for sulphocyanide toning. The bath he used, however, was a phosphate bath, and certainly there was nothing lacking in the quality of the results. Mr. Hodd, continuing, said that he would be prepared to tone sixty quarter-plate prints with a grain of gold, choosing a particular brand of paper. Mr. Hodd subsequently demonstrated the trimming and mounting of the stereoscopic pairs of prints, using a revolving cutting table, by which the first of these operations was largely facilitated.

Mr. A. L. HENDERSON was sanguine enough to express the belief that the time would come when stereoscopic photography would supersede, or at least dominate, the commoner branch. As regards the question of keeping the component prints of a stereoscopic pair of an equal tint, he was inclined to the view that the effect would be better where one of the prints was lighter, so as to give the fullest detail in the shadows, the responsibility for depth of tone falling upon the second print, which might be more deeply printed. The effect might be secured in the printing operation, or by introducing a difference between the size of apertures of the lenses. There was another point which was worth mentioning. Taking a stereoscopic print, he showed that the distance from the margin to a certain spot varied as much as half an inch. How, then, he asked, could that half inch of view, which appeared in only one of the prints, be stereoscopically shown?

There ensued a conversational discussion upon these remarks and the pictures passed round, a cordial vote of thanks being passed to Mr. Hodd.

### PHOTOGRAPHIC CLUB.

MAY 31.—Mr. Lewis Medland in the chair.

Mr. J. R. GOTZ described a fluorescent screen for Röntgen-ray work, with the production of which he was intimately concerned. Originally made in Germany, fluorescent screens were now being turned out very successfully in England, and in the one under consideration he ventured to say that English makers had produced a better article than had previously been obtainable. Fluorescent screens, he proceeded to remark, find their chief use in the hands of the surgeons for diagnosis, examination of fractures, &c., and, like the discovery of the Röntgen rays—like Daguerre's discovery, and many others—they owed their being to a fluke or accident. Röntgen happened to have some platino-cyanide salt in close proximity to his apparatus, and noticed that it became excited under the influence of the rays. Barium platino-cyanide is the salt most used, but various other substances exhibit the same characteristics under the influence of the mysterious radiations to a greater or less degree, for example, the mineral williamite, a natural silicate of zinc, of which a lump and some powder were passed round. Nearly all bodies are subject to the penetrative powers of the Röntgen radiations, and, in fact, Italian scientists have found that the degree of penetration varies with the weight of the bodies themselves. Light bodies—wood, skin, flesh, and fibrous substances—offer little resistance, while bone and the metallic bodies offer an increasing amount of resistance. With these metallic bodies alone there is a wide difference in their degrees of resistance. Aluminium is very light (27), while lead is heavy (206). Water is nearly opaque to the radiation on account of its weight, while glass, which is also fairly heavy, is of a semi-opaque nature. Sodium (about 23), on the contrary, is still lighter, and offers less resistance. The salt used for the screens (barium platino-cyanide) is very sensitive, and is made by Johnson, Matthey, & Co., of Hatton Garden. Special precautions have to be taken in preparing the screens, the use of the hands being inadmissible on account of the delicacy of the materials. The salt is emulsified with a special collodion mixture, and is coated two or three times by hand upon a special heavy paper. Mr. Gotz had a excellent six-inch coil, made by Dean, of Hatton Garden, with which, and a vacuum tube, he showed to the members the whereabouts of their vital organs, bones, and other indispensable parts, much to the satisfaction of their owners.

## Patent News.

THE following applications for Patents were made between May 23 and May 27, 1899:—

BOX FOR CINEMATOGRAPH FILMS.—No. 10,742. "An Improved Receptacle or Box for Preserving Cinematograph Films." J. H. JACKSON and H. R. NATHAN.

PRINTING.—No. 10,733. "Improvements relating to Photographic Printing." Communicated by R. B. West. Complete specification. H. H. LAKE.

RÖNTGEN-RAY TUBES.—No. 10,877. "An Improved Method of, and Arrangement for, Protecting the Anticathode in Röntgen Tubes." C. H. F. MÜLLER.

SHUTTERS.—No. 10,933. "Improvements in Connexion with Photographic Roller-blind Shutters." J. E. THORNTON.

INTENSIFIER FOR SILVER PRINTS.—No. 11,025. "Improved Process for Intensifying Photographic Silver Prints." Communicated by the Actien-Gesellschaft für Anilin-Fabrikation, Germany. C. D. ABEL.

BACKGROUND STAND.—No. 11,043. "An Improved Photographic Background Stand." G. HOUGHTON and W. SALMON.

CINEMATOGRAPHS.—No. 11,059. "Improvements in Cinematographs." A. J. JONES and L. JONES & Co., Ltd.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### PHOTOGRAPHERS AND ASSISTANTS.

To the EDITORS.

GENTLEMEN,—We hear a great deal of the photographic assistant's hardships, but who is to blame in this matter? I have advertised five times in your paper, and had each time one or two replies, and on every occasion engaged a man, and sent word of same to others I have been in communication with, and after waiting about a week, in fact just about two days before the time they should drive up, I get a letter, saying they had engaged with another firm previous to my telegram, which I always send, with a letter following, and I always, when writing to assistants, enclose stamped addressed envelopes; what becomes of these I can't say, but I seldom get a reply, and I am not sure which costs the most, to advertise oneself or reply to advertisements of assistants.

Now, Sir, we hear a lot about the photographer keeping specimens such a long time. My opinion is that, if the assistants themselves were a little more businesslike, there would be less complaints from that quarter. My experience of the usual photographic assistants is, they are a lot of humbugs; they close with the first place they can get, at the same time they are striking a bargain with some other firm, and in the end they close perhaps for a little more money, and perhaps get thrown out soon after. I have actually known a man, applying to me, send another man's letter to me, pointing out what he had been offered. Of course, I have not engaged him. I suppose there will be plenty to reply to this, and then, Mr. Editor, I will let you know how I have been treated by photographic assistants. I am not at all surprised that girls are outdoing the men.

A photographer should decide quick, and an assistant should do the same, and if this was done always it would give the others a chance.—I am, yours, &c.,  
A PHOTOGRAPHER.

### A SOCIETY FOR PHOTOGRAPHIC PRINTERS.

To the EDITORS.

GENTLEMEN,—It appears Mr. Willatt is unable to appreciate the distinction between trade unionism and trade union policy. When he stated in his letter of May 15 that I viewed the matter in one way only, i.e., through already organized unions, he was making a statement against my idea of unionism; for, obviously, no one can advocate more than one policy or course of action. Hence it becomes very material to the point to know what I have written in 1895, 1896, 1897, &c. I have certainly in this discussion, quite consistently, advised a single policy, but that is no ground for justifying Mr. Willatt's sweeping assertion, unsupported by a fragment of evidence, in which he attempted to fix upon me his own individualistic and narrow interpretation of the functions of a trade union. I say again, I am not in favour of organizing photographic assistants in sections as a printers' union, operators', artists', or errand boys'. With such unions the cost of organization and high charge for working expenses would tell against them being really effective, and, although Mr. Willatt has uttered some magnificent, soul-stirring, high-sounding phrases, he has not noticed this and similar little matters of business. His main idea is to start something to improve and assist the photographic printers—a laudable enough ambition, yet scarcely a definite enough scheme to take into the market-place, workshop, or printing-room; moreover, it is evident he is unable to bring the aforesaid laudable ambition into the region of the normal intelligence. His "idea" is regulated by reason, argument, fact, evidence, little of which are discernible in his "plain and precise" statements.—I am, yours, &c.,  
JOHN A. RANDALL,  
June 3, 1899.

### PHOTOGRAPHS REGISTERED:—

O. E. Weale, 3, Victoria-road, Tamworth.—Photograph of Mayor and Corporation of Tamworth.

The Worthing Portrait Company, 4, Railway-approach, Worthing.—Photograph entitled "An anxious moment."

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

J. C. Abertillery).—It appears to be a matter for legal action.

ADDRESS WANTED.—Will Mr. Hector E. Murchison kindly send us his address?

AJAX.—The Hon. Secretary, 12, Hanover-square, W., will, doubtless, send you a ticket on request. You might mention that you ask at our suggestion.

STAINED PRINTS.—N. W. The red stains are clearly caused by the mounts. The chocolate enamelled surface is freely soluble in water, and the red in it stains the print when the wet starch comes in contact with it in the mounting.

HAND CAMERA.—INQUIRER. We do not know of any hand camera in the market for about four or five pounds that is fitted with an anastigmatic lens. The lens alone for a quarter-plate camera would be about the sum named without the camera.

OXALATE OF POTASH.—BRISTOL. Yes, you can make oxalate of potash by adding a solution of oxalic acid to one of carbonate of potash; but, unless your consumption is very large, you will find it more economical to purchase the salt ready-made.

MAKING GELATINE INSOLUBLE.—J. WILLIAMS. If chrome alum does not make the films as insoluble as you require, try formalin. It should be borne in mind that the full insolubilising action of the alums does not take place till the gelatine has been dried.

BROMIDES FOR PLATINOTYPES.—DOUBTFUL. If your townsman is supplying bromide prints as platinotypes, he is defrauding the public, and lays himself open to a prosecution, subjecting himself to heavy penalties. Any one can put the law in force against him who has been defrauded. You can, for example, if he supplies you with a bromide print when you have paid to have a platinotype.

LENS QUERY.—L. MUNROE writes: "If I mount the two lenses of an opera glass, with their convex sides outwards, in a tube with stops midway between them, can I use the combination as a photographic lens, and will it be rectilinear?"—Yes, rectilinear, if the stop be placed midway between the glasses. But the field will be very round, and only a small plate will be covered, even when a very small stop is employed.

VESSELS FOR HYPO FIXING SOLUTIONS.—HYPO asks: "Will zinc trays, such as are used in carbon printing, do for fixing silver prints and bromides? If not, would enamelled iron ones do better?"—Zinc will not do at all, as the metal would be acted upon by the hyposulphite of soda. Enamelled iron will do very well, provided the enamelled surface is perfect; but if not, and the iron is exposed, the silver prints would be stained by contact with it.

LANTERN LENSES.—G. LAME asks: "Would a whole-plate rapid rectilinear lens be suitable for use with a lantern? If so, what size condenser would be required, and what distance should the lens be from the condenser, focus of lens in camera, about eleven inches?"—The lens could be used, but the image would be very small unless the screen is placed a long distance away, and that will entail a great loss of light. If the slides used are of the ordinary size, a four-inch condenser will do. Its distance from the lens will have to be about double that from the lenses ordinarily used for the lantern.

COPYRIGHT.—W. E. B. writes as follows: "The publishers of a local newspaper have brought me a photograph of a group of royalty to copy, to be reproduced in their paper. The photograph was taken by —, and I expect it is copyright. Shall I, if I execute the order, run any risk if the picture is copyright, seeing that I am ordered by the proprietors of the paper to make the copy?"—Certainly, unless the proprietors of the paper have the sanction of the photographer to reproduce the picture. If you have any doubt about its being copyright, and there is little doubt that it is, you had better get an agreement from the proprietors of the paper to indemnify you in any costs you may be put to in case of an action, or, better still, not undertake the copying at all.

COLOUR SCREENS.—DIP THE DYER asks: "Could you give me the reason why the enclosed screens have dried in so unsatisfactory a manner? Gelatine used was Heinrich's. For the circular glass I boiled gelatine and dye together, and poured on hot, to dry slowly (acid green aniline dye). The square plates are lantern plates, fixed and washed, and, while wet, put in a solution of dye and water. These are brilliant green and acid green. I have tried dissolving dye in alcohol, but it's not a success. I may say, on several occasions I have made red, yellow, and blue screens without a flaw. Could you suggest the addition of any fluid to the gelatine and water? I have tried ammonia, with disastrous results."—Too much colour has been used, so that it has crystallised out of the film as it dried. The crystals can be rubbed off the surface, they are so thick.

## EX CATHEDRA.

WE are informed that the next Traill Taylor Memorial Lecture will be delivered by Colonel J. Waterhouse, I.S.C., Honorary Secretary of the Royal Photographic Society. The subject will be, "Teachings of the Daguerreotype," in connexion with which Colonel Waterhouse has for some time past had a number of experiments in hand.

AN adaptation of a very useful device for taking enlarged images at one operation has been patented by an American optician named Nehring. He terms it an enlarging and copying lens. We learn that the lens has created "surprise" in photographic circles. It is meant to fit between the combinations of a double lens, and "when placed there the camera can be used to copy pictures, or photograph any object with enormous amplification." Thus, with hand and other cameras having comparatively small focal extension, it is possible with Mr. Nehring's attachment to obtain a portrait head or a portion of any other subject so large as to fill your plate with it. The idea, it may be pointed out, is not a new one. Amongst others,

the late Mr. J. Traill Taylor frequently commented on its practicability; indeed, at p. 89 of his book, *The Optics of Photography*, published in 1892, he describes and figures the idea under the heading of focus adjusters for lengthening the foci of lenses, by inserting such adjusters between the combinations of an existing lens.

\* \* \*

It is officially stated that after June 24, the Royal Photographic Society's address will be No. 66, Russell-square, Bloomsbury, W.C., where all communications, after that date, should be addressed. As previously announced, the President and Council will hold a reception of the members of the Society, and of the affiliated societies, at the new home, on Tuesday, June 27, at eight p.m.

\* \* \*

WRITING in our ALMANAC for 1898 on the subject of animated photography, we prophesied—in fact we believe that in this country we were the first to direct attention to the matter—a great future for what is now termed the parlour mutoscope. The form of instrument controlled by depositing the nimble penny in a slot has already delighted millions of people in London and the country, and it is now proposed by the companies exploiting the biograph and mutoscope patents to put parlour mutoscopes on the market, so that ere long these highly interesting developments of the principle underlying the old wheel of life or zoetrope may possibly be as common in the home as the stereoscope once was, and probably will be again.

\* \* \*

AGREEABLE dividends of twenty-five per cent. have recently been paid by the Mutoscope and Biograph Companies, and joy must naturally have taken possession of the hearts of the shareholders. The speakers at the various meetings appear to be confident that animated photography is not a passing fad, and that—of course, this is an inference that is read into the context of the quoted remarks—dividends of twenty-five per cent. will continue to be forthcoming. We do not think they will long be made out of public exhibitions of animated photographs. By-and-by it is safe to assume that animated photography will secure great patronage at the hands of large advertisers, and then farewell to it as an attraction at music halls and suchlike places. At any rate as a "draw" it may

be safely relied upon to have its day and no more. However, the possibilities of the mutoscope have yet hardly been touched at their fringe, and there is no doubt that an enormous amount of money is to be made out of popularising the idea. Of course, it is very largely due to American enterprise that animated photography and mutoscopy are so successful just now. Why do not some of our home manufacturers have a "cut in" at the latter branch, we wonder?

\* \* \*

NEW YORK is to be the scene next autumn of a great International Photographic Exposition. It will be held at the Madison-Square Garden during the week October 21 to October 28. It is stated that there will be exhibitors from France, Germany, Austria, and England, and a representative is said to have arrived here for the purpose of superintending the shipping of exhibits to New York. The scope of the Exhibition will be understood by an extract from one of our American contemporaries, which says that it will be made particularly interesting by the many demonstrations of processes of manufacture. The construction of cameras will be fully illustrated, and one concern will, in all probability, start with the rough wood, and show the whole construction of a popular make of camera from start to finish. A photographic paper house will demonstrate their products, and invite visitors to bring their own negatives for this purpose. The embossing and gilding of mounts, the grinding of lenses, testing of lenses, and the making of camera bellows will also be features. At least one photographer will have a studio with electrical installation in actual operation. Demonstrations of printing-out papers, platinum paper, carbon printing, shutter-speed testing, film-developing, and the like, a display of magazine cameras, a photo-engraver's exhibit, and the applications of photography to meteorology, astronomy, and the sciences are listed amongst the attractions.

\* \* \*

FURTHER, there will be a special loan collection of historical exhibits, and the steps by which the present-day simplified methods have been attained will be shown. A special department will be the optical and magic lantern section, in which acetylene, electric light, limelight, and oil lanterns will figure. The progress made in animated photography will be illustrated, and the advances in the application of the X rays will not be lost sight of. It is said that the Exhibition will be under the general management of Mr. Ernest R. Franks, who piloted successfully the great Cycle Shows of 1895, 1896, and 1897. The executive offices are 11, Howard-street, New York. We are indebted for the foregoing particulars, as we have said, to an American contemporary; no direct information has as yet reached us. The fact that an American representative has come, or is coming, to this country points to the supposition that considerable English support is anticipated. We are not sanguine that the English houses will take a very enthusiastic view of the matter, particularly as the Paris Exposition is so near, and the advantages likely to accrue to English exhibitors at an American Exposition are not easy to perceive.

\* \* \*

THE dearth of interest in British photographic societies and kindred institutions and the failure which is only too frequently their fate is a theme which, for years, has excited comment in these pages. But, if we go farther afield, we see that much the

same state of things is prevailing. We find an Australasian contemporary drawing a very gloomy picture of the condition of photographic institutions in Sydney, New South Wales. It tells us that a long-felt want is discovered, or said to be, quite the correct steps are taken to fill it, a wild burst of jubilation fills the air, and some of it gets into little out-of-the-way paragraphs in the local press. "A few youths who fondly believe, and try to hope they can run the whole show, stagger along under a temporary deluge of fame derivable from mutual back-scratching, lose their heads in a sense of their own self-importance, disgust the solid element of the partnership by their overweening conceit, and anger, hatred, envy, malice, and all uncharitableness take the place of those flatterer professions of desire to "further the interests of photography," which were declared to be the foundation-stone of the structure. Then a sale, an empty room, and a more or less prolonged interval of rest until somebody else arises with a mission to "try it again." There is no exaggeration about this. The picture is a familiar one in all parts of the Australian continent where photographers most do congregate."

\* \* \*

ADDRESSING itself to details, our contemporary adds that the Photographic Society of N.S.W. has sold off its property and given up its rooms, and its present address is a steam launch lent by one of its members, which leaves Circular Quay at irregular weekly or fortnightly intervals to follow a yacht race. The Austral Camera Club is a private one, and therefore exempt from comment. The Railway and Tramway Camera Club, the Lands Office Society, &c., are purely departmental, and there are hundreds of earnest and enthusiastic photographers, both professional and amateur, residing in and within a few miles of Sydney, who are perforce compelled to go "on their own," for the simple reason that there is no club to which they can gain admission. The people who are directly responsible for having "messed up" photographic society work in Sydney take refuge behind the statement that "members would not pay up." The members referred to say that no value was offered in return for the money, and there was no visible advantage to be derived from belonging to a club which had no advantages to offer. This is indeed a melancholy condition of affairs for such an important centre and town as Sydney, N.S.W. Here at home desolation does not go so far as this; but the continued failure of societies designed to benefit professional photographers suggests the reflection that, as a class, they are long past helping.

\* \* \*

MESSRS. L. GAUMONT & CIE. of 25, Cecil-court, Charing Cross-road, London, W.C., inform us that they have accepted the agency of Messrs. Lumière & Fils of Lyons, for Great Britain, India, and the Colonies; and that they have become their sole representatives in those countries. They have now a stock at the above address of Messrs. Lumière's chief products and manufactures, briefly surmised as follows: Orthochromatic, panchromatic, and ordinary dry plates; rigid vitreous films, orthochromatic, panchromatic, and ordinary; chemical products, including developers, the Lumière cinematograph machine and collection of over a thousand films. With reference to the foregoing, Messrs. Fuerst Bros. ask us to note that they will supply the goods of Messrs. Lumière to their customers and to the trade in the future, the same as they have done during the past five years.

## THE COPYRIGHT UNION AND THE PROPOSED COPYRIGHT BILL.

DURING the last two months we have made several references to the Copyright Bill, now before the House of Lords, in so far as it proposes to amend the existing law of copyright as it relates to photographs. In our issue of May 5 we gave an article which elucidated the principal points of difference between the old Act and the Bill under consideration. On May 26 we published the essential parts of the Bill, so that our readers have had brought to their notice the whole of the provisions which it is sought to substitute for those that have governed the law of photographic copyright since the year 1862.

It has been doubtful up to the present whether any action would be taken to protect the rights of photographers in copyright as they might be affected by the contemplated measure. The Royal Photographic Society appointed a Committee to consider the Bill, but, up to the present, nothing has come of that action. It is an open secret that the promoters of the Bill, chiefly members of the Royal Academy, were disinclined to listen to the views of representative photographers on those parts of the Bill by which their interests were concerned, and thus no opportunity was available for amending the measure before its presentation to the House of Lords. It certainly must appear to the lay mind a very strange thing that a proposed piece of legislation vitally affecting the legal rights of such a numerous and growingly important class as photographers should not be drawn up in consultation with those best qualified to judge how far the reasonable requirements of that class are likely to be met.

Fortunately a Select Committee of the House of Lords has the Bill under consideration and is taking evidence upon it. The Photographic Copyright Union has applied to be heard before the Committee, and witnesses will be called to give evidence on certain points of importance. Opinion, so far as it has been expressed by photographers on the provisions of the proposed measure, is favourable to the Bill, because at the first glance it does not vitally interfere with the copyright now enjoyed by photographs under the Act of 1862 (an Act which, from the photographic point of view, has been found to work extremely well), but the legal advisers of the Copyright Union have indicated certain clauses, which, if passed, will press unfairly on photographers; while, in at least one case, a state of things will be created which will entirely upset the present harmonious working of a most important branch of copyright practice.

It may be well if we briefly indicate those parts of the Bill to which the Union takes exception. It is proposed to reduce the existing term of copyright from forty-two years, or seven years after death, to thirty years. On what ground this alteration is to be made is not clear. Copyright in photographs is to-day surely not less valuable than it was thirty-seven years ago; on the contrary, it is easy to argue, and just as easy to prove, we imagine, that it has increased rather than decreased in value. The wide-spread employment of photography in all the arts and sciences, its growth as a reproduction process, its increasing uses for the portraiture of distinguished people, as a method of recording vanishing buildings of historical interest, scenes of national interest—indeed, its constantly augmenting utility in all the affairs of daily life supply an overwhelmingly powerful plea in favour of placing photography on the same footing as fine art. It will be a grave injustice if the term is

reduced, and we hope the Copyright Union's witnesses will be emphatic in their protests against any alteration.

An equal degree of perplexity asserts itself when we come to inquire why, after a lapse of thirty-seven years, the Legislature is to be asked to throw over the classification adopted in the Act of 1862, and draw a sharp distinction between works of fine art and photographs? The distinction, *per se*, would not matter in the least if it were not made the occasion of an attempt to whittle away the photographer's enjoyment of copyright. It is not opening up an argument over the right of photography to rank as a fine art in pointing out that, if it were worthy of so being classified, for legal purposes, thirty-seven years ago, the lapse of time has hardly operated to deprive it of that right. On the contrary, it is but a commonplace to assert that the very large strides made by photography as a means of pictorial expression since the existing Act was passed strongly confirm and emphasise rather than depreciate its claim to recognition as a fine art, for purposes of legislation. It will be the object of the Copyright Union to remove the distinction it is sought to draw in the proposed Bill, and if success in that object is achieved a great gain will result, for, in matters of copyright, photography will enjoy all the rights conferred on the recognised fine arts.

Perhaps the most important and far-reaching clause in the Bill is that which deals with the relations of sitters and photographers. At present, where a sitting is not paid for and "consideration" is given, the copyright in the photograph so obtained vests in the photographer, who is free to do as he pleases with it and to impose his own terms for the right of reproduction. A clause dealing with copyright in portraits which we here quote would completely revolutionise this state of things.

The clause runs: "In case any work the subject of copyright under this Act shall be a portrait made on the request of any person for valuable consideration, though the copyright remain in the author or his assigns, no person, whether the author or his assigns or not, shall be entitled to make a copy of such work, or to sell, distribute, let for hire, or exhibit such work or any copy thereof without the consent in writing of the owner of such portrait for the time being. Such owner shall have all the rights of an owner of copyright under this Act to prevent infringements of this section, and to obtain the seizure of copies dealt with in breach of this section, except that it shall not be necessary, in order to enforce such rights, for him or for the portrait in question to be registered under this Act. For the purposes of this section any work shall be considered a portrait whose principal object is the representation in any form of art of any person."

So that, if we understand this somewhat involved clause aright, the photographer may take the portrait of a celebrity without receiving payment and yet be unable to exercise the right of publication in any shape or form without written permission. The latter condition would introduce a very disturbing element in every photographic business; and indeed it is doubtful if it would be found workable. One thing is clear, that the Bill proposes to substitute for the present satisfactory relations between photographers and sitters who are photographed without payment a set of conditions which would very seriously hamper publication photography, a constantly growing branch, and render difficult if not impossible the relation between photographer and sitter on the one hand and between photographer and publisher on the other. As it was

put to us by a well-known authority on the subject, the clause we have quoted would kill the publication trade.

The crowning absurdity of the Bill is that which invests a common informer with the right, to be granted by a magistrate, of taking a policeman to search anybody's premises suspected of containing photographs contravening the provisions of this Bill. A or B has only to suspect that you possess some photographs which are somebody else's copyright, and your house can be invaded as if you were a malefactor. This and other clauses we have referred to reflect no credit on the common sense or intelligence of the draughtsmen of the Bill, and which we hope will be purged of them in its passage through Parliament.

**Photography a test for Reagents.**—Messrs. Lumière Bros.' process of development with acetone, &c., has been put to a novel use by them in a mode of detecting the presence of these bodies by their photographic behaviour. To apply the test, 25 c. c. of an aqueous or alcoholic solution of the substance under examination is mixed with double the quantity of solution containing seven per cent. sulphite of soda, and one and a half per cent. of pyro or a similar hydroquinone solution, and applied to a plate acted upon by light. A similar test solution is diluted with an equal bulk of water, and applied also to an exposed plate, and the two plates are compared. The method is so sensitive, that it will detect formaldehyde (formalin) diluted 25,000 times, acetaldehyde 15,000, and acetone 2500 times.

**Measuring Volumes.**—The use of flasks for measuring liquids would, we think, be much more common if their innate usefulness were more known. The "graduated measure," or, as the Americans term it, the graduate, is the usual agent employed by the photographer; but it has many disadvantages. Where very close accuracy is not needed, a most excellent substitute for them is found in an ordinary glass bottle, preferably one with a wide mouth. We know one well-known photographer who has for all ordinary purposes abandoned graduates in favour of bottles for measuring the ingredients of batches of developing solution. He keeps a set of bottles of one, two, and four-ounce capacity at hand, using one or the other as needed, and he prefers them to the ordinary glass measures. When mixing larger quantities of liquids, or when making standard solutions for stock, measuring flasks may be obtained which indicate with great exactitude. In measuring, for example, the acids in making pyroxyline, open measuring glasses, even those of cylindrical form, are entirely inadequate, and flasks should be employed, as upon the precision of quantities employed depends entirely the quality of the product and its uniformity; indeed, it may be questioned whether the method of weighing is not still better, but certainly no graduates should be used. The requisite quantity of water should be either taken up by a pipette or measured from a burette; but those who have personally taken up pyroxyline-making can understand the absolute accuracy needed to ensure uniform results. A difference of ten grains of water in two pints of acid would make a difference of two or three per cent. in the weight of the gun-cotton produced, and, as is well known, the best test of uniformity of product from a given formula is to be found in the amount of increase of weight the cotton-wool takes on by the treatment with the mixed acids.

**A New Lithographic Process.**—The "Wharf Litho" is the name given to a new method of lithography recently described in the *Times*, and which possesses features of so entirely novel a character that it will be well to draw attention to them on the possibility of the principle being adaptable to photographic purposes. The broad principle of lithography is the production of a picture in pigment held in a greasy medium upon a partially porous surface. To print from it, the first operation is to pass a moist sponge over all; this wets the parts of the stone uncovered by the picture. An

inked roller is then passed over the stone; the wetted surface repels the ink, but the greasy picture takes it up. If now a piece of paper be laid upon the inked stone and the whole passed through a press, a print is the result. This is a rough outline of a process which has many little details of manipulation. In the Wharf Litho process all wetting is done away with, and the stone is replaced by zinc, prepared in such a way, by means of chemical action not yet made public, that the non-picture portion is self-repellent of the ink. The practical result is that printing can be carried on quicker through absence of periodical delays to work up the image, &c., and the press can be run at a much quicker rate. It is, of course, impossible to make any suggestion as to photographic use till the patent specification is published; but, seeing the process is of a chemical nature, it is permissible to hope that photography may be able to utilise it.

**Preparation of Pure Silver.**—Herr Otto Pfeiffer, in the *Chemiker Zeitung*, describes a method of treating residues so as to obtain pure silver for dissolving and making nitrate. He dissolves residues in strong ammonia, distils off the surplus ammonia, and precipitates the chloride with pure hydrochloric acid. The washed chloride is then placed in a porous cell with dilute sulphuric acid, the cell being also surrounded with similar weak acid. In the porous cell is placed a piece of platinum foil, which, by means of a platinum wire, is connected with an amalgamated zinc plate immersed in the outer acid. The apparatus is left for a day or two, and the reduced silver well washed with water.

#### ON THINGS IN GENERAL.

I HAVE read that surprise is felt that the recent great advance in X-rays technica, the Wehnelt interrupter, has been so little noticed, considering the important alteration in methods and the vast improvement in results that follow its adoption. That these changes are improvements, vast improvements, is true beyond the shadow of a doubt. An explanation for this supineness has been offered in the need that exists for a high voltage to bring out the efficiency of the new contact-breaker, and, seeing that 50 or 100 volts is desirable with even a comparatively small coil, there is something to be said for such ground being taken. But this is not all; it is indeed very possibly only a minor operating factor. It is in all probability that the true cause of the indifference manifested is the fact that manufacturers of coils have no interest in seeing the successful introduction of the Wehnelt apparatus, for it is so simple that one could be extemporised in a very short time with a glass tumbler and a sheet of lead as the principal parts of the new arrangement, its use requires a coil of quite simple construction in comparison with those now made. No condenser, no expensive spring or mercury break of the old type, and the production by the simplified arrangement of a spark twice or three times as long as with a similar-sized coil made with the older essentials. *Verbum sap.*

When I read all the details of the new Copyright Act, I feel inclined to exclaim *parturient montes*, &c. What have we gained, except an emphatic distinction between works of fine art and photographs (the latter being classed with "casts from nature"), a reduction of the time of continuance of copyright, and a very emphatic difference between the results of the brainwork of the photographer and of the painter. When the latter is commissioned to make a portrait and makes it, the copyright belongs to him; but, when a photographer is commissioned to make a portrait and is paid therefor, the copyright does not belong to him. His work is classed with the boarding-school Miss's clay cast of a fern leaf; indeed, if the latter did a fern leaf in poker-work, I am inclined to think she would have the "pull" over the photographer as regards copyright. Perhaps I have not read the Bill aright. I hope not, for the credit of those praiseworthy gentlemen who have taken such pains over photographic interests in the matter.

The Rev. F. C. Lambert, whose knowledge of optics is well known, has been giving an explanation of the well-worn problem why we

do not see objects the wrong way up. He speaks of the retinal image "which we, by an unconscious mental action, reinvert." Philosophers without end have attacked this problem, always with unsatisfactory results to their disciples, and, though the reverend scientist has followed in their footsteps, it will not be difficult to show where they have all gone astray. They have gone to optics and psychology when it was English grammar they should have called into requisition. It is, without doubt, purely a question of etymology, of the meaning of words. When we speak of an object being visibly "inverted" and "reverted," we must have a standard of comparison, and that standard a visible standard. Now, where is that standard to be found? Let us take Macaulay's New Zealander, standing on London Bridge. We tell him he sees the bridge upside down really, but he makes it all right in his head. This would be so much nonsense to him. If, standing there, the then visible sky was at his feet, and the bridge over his head, he could understand the matter; but nothing whatever is "inverted or reverted." He has only one standard, we all have only one standard, and the eyes act up to it. It would be every bit as reasonable to say that "the blood relations of Macaulay's friend, who, in a small part of their land, are immediately under our feet, have attained a habit of re-inverting the objects they see, because really they are standing on their heads and don't know it; they have, in fact, become used to the thing from their birth, and so don't notice their absurd position; and, indeed, were it not for the fortunate existence of the laws of gravity, they would drop off into the sky."

At a discussion on developers the other day at the London and Provincial Photographic Association, a member said of sulphite of soda solution that, after being kept some time, it failed to give the same blackness of the image, although the solution had undergone no change in appearance. It would be very difficult to imagine what change in appearance it could be expected to undergo; but, unless it were kept in an hermetically sealed vessel, it certainly would be likely to change in constitution, though not in appearance. It might be expected to gradually absorb air and become converted into sulphate, after which the explanation of its ceasing to give the same blackness is self-evident.

There is generally food for thought and plenty of valuable information to be gleaned from a perusal of the reports of the meetings of the above-named Society. Take, for example, the Mr. Beckett's revolutionary dictum that Judges should give reasons for their decisions, and that in this way an incalculable amount of help was to be given. Now, he was perfectly right; an immense amount of good might be done, and the ambitious student learn a great deal, but there is a deal of human nature in human nature, and I don't think Judges generally in practice will depart from the advice of the old Judge to the young one: "Never give reasons for your decision."

Some one asked the other day how to retain the gloss on enamelled prints when mounting them, and the reply was to paste two or three thicknesses of paper on the prints while they were squeegeed upon the glass. A still better plan is to use one thickness of waterproof paper in a similar manner. Such paper, made for the purpose, is now regularly obtainable from the dealers in materials.

On the subject of tips, another may be given. Reference was recently made in the JOURNAL (LANTERN SUPPLEMENT) to cleaning out the nipple of an oxyhydrogen jet when it had become roughened by use. An excellent extemporised file for this purpose may be made by taking a fine knitting needle and rubbing it with a piece of emery cloth of medium grain tightly held between finger and thumb. A splendid file is so produced, which answers the purpose admirably.

The letter on "Photographers' Assistants" in last week's JOURNAL emphasises in the extreme my remarks showing that there were two sides to every question, and so, in consequence, with that touching the grievances of these long-suffering men. As I before said, they are subjected at times to what is neither more nor less than cold-blooded cruelty in the retaining of their specimens. But it is well known to all employers that, in many cases, such retention is mainly owing to their own gross carelessness and want of thought in the way they dispatch their specimens, badly packed, and without the slightest indication upon them as to where or whom they come from.

A man wants the patience of Job to sort them and return them all to their legitimate owners.

I hope Mr. Everitt will not think me discourteous in being so long in replying to his note putting certain queries to me. It escaped my attention till so long after, that I thought it would be better to include it in my usual periodical lucubration. To query the first, I should say, I should find it very difficult indeed to show that a point moving half an inch in  $\frac{1}{500}$  or  $\frac{1}{5000}$  of a second would not be represented by a line, whether straight or curvilinear. As to his second query, I should not attempt to show that every part of a horse in gallop moves at uniform velocity, for they do not. Possibly the fetlock might be looked upon as the portion whose progressive motion at times was the slowest; but, then, we look at the fetlock of a cart horse rather than a race horse for a manifestation of hair.

FREE LANCE.

### "KACHIN"—ANOTHER NEW DEVELOPER.

STILL they come, the new developers. The latest addition to the list is "kachin." It is, I believe, not yet on the market, but I have been favoured with a sample, with which I have experimented somewhat largely, in comparing it with other developers, old and new, and the result, I think, may be of interest alike to professional and amateur readers of the JOURNAL. I may at once say, as an old photographer, that my pet developer has hitherto been the "good old pyro," which, perhaps, is still more largely used by professionals, and some amateurs, than all the other developers put together, at least in this country. It must, however, be confessed that our old friend is not all that could be desired. For example, it cannot be used, when mixed with the accelerator, for more than one plate without risk of staining the film; also, in a prolonged and forced development, the film is in danger of being stained, unless the solution is changed from time to time. Another serious objection to pyro with many is that it stains the fingers and nails badly, and the stains are difficult of removal. This drawback is not a very serious one with professionals, who, as a rule, are not over-squeamish as to the appearance of stained fingers. The case, however, is different with amateurs.

The newer developers, the majority of them, are free from the above inconveniences, but, unfortunately, they are, for the most part, accompanied by others from which pyro is free. For instance, metol is free from finger and nail-staining, but with many persons it has a very pernicious action on the skin. Amidol, again, though free from this latter evil, stains the nails, and it does not keep well, as the crystals become discoloured. Eikonogen, like metol, is difficult of solution. Hydroquinone and glycin are slow in action, and the other newer developers have their drawbacks, more or less.

What seems to be required, to be the perfection of a developer, is one that embraces all the best qualities of the others, while it is free from their undesirable ones. So far as my experience has gone, kachin more nearly approaches that ideal than any other with which I am acquainted. Of its chemical composition I can say nothing. All I can say is, that it is in fine crystals that do not seem to deteriorate, even when freely exposed to the air. It dissolves directly it is put into water, almost as quickly as pyro does. I believe I am correct in saying that, like all the new developers, and our pyro now, it is "made in Germany."

Here are formulæ for the developer:—

#### A SINGLE-SOLUTION DEVELOPER.

Water .....	200 grammes.
Sulphite of soda .....	5 "
Carbonate of soda (crystals) .....	10 "
Kachin .....	2 "

#### A TWO-SOLUTION DEVELOPER.

##### SOLUTION A.

Water .....	250 grammes.
Sulphite of soda .....	25 "
Kachin .....	5 "

## SOLUTION B.

Water .....	250 grammes.
Caustic soda (pure sticks) .....	5 "
Phosphate of soda .....	47 "

For use mix one part of A with one part of B and one part of water.

In making the B solution I find it better to dissolve the caustic soda first and add the phosphate afterwards, it then dissolves more quickly than when the two salts are put into the water together. It is the two-solution developer that will be found the best for general use, as it is more energetic in action than the other, a plate with a correct exposure being fully developed in from two to three minutes. With the single-solution developer the time is longer, and, in my hands, it does not yield so much detail in the case of under-exposed plates as the other, even with a prolonged development. It is, however, for that reason better adapted for plates which are known to be over-exposed, particularly when it is restrained with a bromide, the effect of which with kachin I shall say more about presently. The single-solution developer, when diluted with an equal bulk of water, makes an excellent developer for bromide papers. The negatives developed with kachin do not reduce in the fixing bath, like those by some other developers, therefore they should not be made denser than they appear in the solution. The finished negatives are particularly clean and clear in the shadows, though full of detail, while the lights are a fine black, with good printing quality. The negatives, being of a vigorous character, are as well suited for platinotype and carbon printing as they are for the P.O.P.'s.

It may be well to refer to a few of the comparative experiments I have made with kachin and other developing agents. These experiments, it may be mentioned, were all made on half-plate or the  $7\frac{1}{2} \times 5$  size, exposed in a bi-lens camera with accurately paired lenses of about six inches focus used with their smallest stops. After exposure the plates were cut in half, thus giving two plates absolutely identical as regards subject and exposure. Compared with pyro ammonia and pyro soda the results with kachin were much the same as regards detail, but those with the latter developed more quickly and were free from the yellow tint of most pyro-developed negatives. With metol the image appeared rather quicker than it did with kachin, but before sufficient density was obtained the latter had overtaken it, and that negative in the end was finished before the metol one. In the fixing the metol one lost in density, while the other did not. Tried against hydroquinone, it gave more detail in the deepest shadows, and the negative was developed and fixed by the time the hydroquinone one was fully developed. Tried with amidol, the kachin had the advantage, so it had in a less degree in the case of metol-hydroquinone, alike in detail and in density, both with correct exposures and under-timed ones.

A very great advantage in kachin, particularly to amateurs, is that the mixed solutions can be used over and over again — not necessarily the same day — and, until many plates have been developed in it, there is no appreciable loss of energy. The mixed developer may be kept for days, even after many plates have been developed in it, and it will still work well, though it will require a little longer time. Some solution, in which several negatives had been developed, was left standing in a beaker simply covered with a glass plate for five days. It had then become of a faint pinkish straw colour, but it developed well, and was but little slower than at first; also, the negatives were perfectly free from stain. I have a large bottle, into which the kachin solutions after use have from time to time been put. Some of it must be three weeks old, and taken part in the development of dozens of negatives. On trial to-day it worked all right, though, as might be expected, it was slower in action than that newly mixed; but the negatives were perfectly free from stain or veiling.

Reference was made just now to the effect of bromide with kachin. With normal exposures no bromide is required. In the case of over-exposures, however, it is a great power at command, and a little goes a long way. A few drops of a ten per cent. solution of bromide of potassium to the ounce of developer has a great restraining power, and a considerably over-exposed plate may, by its

addition, be made as good a negative as if it had been correctly timed. Indeed, with an excess of bromide, a much over-exposed negative may be made to look like an under-exposed one. As an experiment a plate was given perhaps twenty times the correct time. One half was developed with the normal solution, and, as might have been expected, the image flashed out at once, and, except the deeper shadows, was quickly buried. For the other half the developer was restrained with about six grains of bromide to the ounce of solution. This negative was a good printing one, and did not appear to be very greatly over-exposed.

Although I have developed many dozen plates with kachin during the past three weeks, there are no stains on, or other inconvenience to, either the skin or nails of the fingers. This fact, coupled with other advantages accredited to this new and latest developer, will, no doubt, be highly appreciated by amateurs.

There is one curious, and at times valuable, property in connexion with kachin that I had almost forgotten to mention. Wishing to test it under all conditions, I tried it with some stale plates, some years old, of different brands against other developers, pyro, metol, and hydroquinone. With all the latter the negatives showed the well-known characteristics of stale plates in a marked degree, but the halves developed with kachin were much the best; with one brand, almost free from any stain whatever. In all cases usable negatives were obtained, whereas with the other developers the negatives were mostly unprintable. Of course, no one knowingly uses stale plates, but sometimes, when the stock runs out and more have to be purchased, *en route*, at out-of-the-way-places, where the sale is small, one occasionally gets "landed" with some. In such cases I would say, Use kachin for their development.

E. W. FOXLEE.

## THE DERBY EXHIBITION.

THE Exhibition of Photographs which was opened at Derby on Tuesday evening, the 6th instant, is an interesting proof of the influence of one man. Whenever a photographer hears or sees the word Derby, he immediately connects it with the name of the late Richard Keene. It is safe to say that, but for the example he set, and but for the work he did, the collection of photographs which the Derby people can now enjoy would not have been shown. Mr. Keene set up for himself a high ideal, and was not content till he reached it. Captain Abney, the President of the Derby Photographic Society (who was, if we mistake not, an early pupil of Mr. Keene's), followed his master's example, and was not content with anything less than the highest class of work; and, judging from the exhibits of the local Society which form part of the collection now on view, each member of the Society seems to be striving after the topmost place; the result is an exhibition of photographs equal, if not superior, to any which has yet been held. It is admitted that the people in the Midlands have a more highly developed artistic feeling than the inhabitants of any other part of England, if we except London. It is not to be wondered at, therefore, that when Birmingham folk and Derby folk take up photography they give us something more than the usual thing; they seem to know, instinctively, what will make a photographic picture, and what to leave alone.

With the assistance of the Corporation of Derby, which has placed the convenient, admirably lighted Art Gallery at the disposal of the Derby Photographic Society, Mr. Crowther, the curator of the Art Gallery, and Mr. Victor Haslam, the Secretary of the Society, have got together a collection of photographs which far surpasses any of the triennial exhibitions which have hitherto been held at Derby. With the greater part of the Invitation Section our readers are already acquainted; but, if possible, they should take the opportunity of renewing the acquaintance. It is not every day they have the chance of seeing W. Crookes' *Old Lady*, nor his *Sheriff Comrie Thomson*, or Harold Baker's *Countess of Warwick*, his *Pleasant Story*, or his *Portrait in Costume*. Here, too, are some of Craig Annan's best works, and H. H. Cameron's ever-lovely *Miss Bagge*, which Mr. Cameron himself cannot hope ever to excel. There is, to us, a new portrait by W. J. Byrne, No. 113, a large head, untouched, taken direct, of fine quality and grand simplicity. There is also work by Smedley Aston, Percy Lewis, A. H. Hinton, O. G. Rejlander, Karl Greger, J. Gale, Dr. Morgan, Paul Martin, A. Keighley, whose No. 54, *A Ryt in the Clouds*, is better even than his older *Gather the Roses*. F. H. Evans sends his wonderful *Sea, and Sky, and Land*, and two very

delicate architectural views. Altogether there are over 200 works in the Invitation Section by fifty of the foremost workers of to-day.

To come to the local exhibits, which are about as numerous as the invited ones. Many were rejected for want of space. We find two of the local professional photographers much in evidence. Mr. W. W. Winter sends frame after frame of first-rate cabinet portraits of the County Council, Derby magistrates, Town Council, and Board of Guardians—all so good that they might be machine-made rather than the work of a human being. He has another frame of larger work, printed in red chalk; but, though the work shows evidence of care and taste, the way in which the prints are displayed—on "rumpled" green velvet—is anything but pleasing. It is a pity professional photographers will not learn from their humbler amateur brethren and frame their exhibits quietly and not loudly. The same loudness is evident in the works of Mr. Dereské; he has a large portrait of a girl, No. 415, which might well have been smaller. This girl, Mr. Dereské tells us, is *An Orange-seller*. We will not contradict him, but we should be sorry to give twopence for all the oranges she ever sold. She may have oranges in the tray under her arm, but the leaves among the oranges are not orange leaves, they are more like daffodil leaves. The pose of the girl is good, but one wishes in vain for a little more nature and a little less art. We hope some day Mr. Dereské will take his camera to sunny Africa or Spain and bring back another orange-seller, perhaps not so perfect but more natural. That he can do simple, truthful work is proved by the landscape with cattle, which shows in No. 410, a *View in Dovedale*, and also by No. 404, a *Study of a Head*, which is printed somewhat after the Bergamasco style—a vignette, with the edges dark instead of light. Mr. Winter's and Mr. Dereské's works were not for competition, and the same was the case with the views sent by Messrs. R. Keene, Limited. For us to criticise the work of this firm would be absurd. All the world knows that, if there are perfect negatives from which perfect prints in platinotype are made by the thousand (for the late Mr. Keene was the first professional worker to take up and master platinotype printing) anywhere, it is at the works of Messrs. R. Keene & Co.

Of the work shown by the members of the Derby Photographic Society, that of the Vice-President, Mr. W. R. Bland, takes the first place; all this gentleman's exhibits were sent in marked "not for competition." If one of his pictures—we use the word picture in its highest sense—is better than another, it is No. 822, an interior view of Wirksworth Church. Every one who has studied either photographs or photography knows how the camera almost invariably fails with interior architectural views, how it never seems to render the feeling which must impress all but the very cheapest cheap tripper when he enters a church or cathedral. The usual interior view gives us every stone, every joint, every tile, every window, every lead, but nothing more; the effects of light and shade, which make even the newest churches at times quite poetical, seem to be things architectural photographers dread, just as, when the collodion process was first introduced, photographers generally waited till the sun went in before exposing. The photograph of Mr. Bland's proves that he has had no such fear, and that he has determined to catch the sentiment of the scene, whether he got every stone or not. Two rays of sunlight have given him what he wanted to express himself with, the rest he got by infinite pains and care; that nothing is left to chance, as some so-called artistic photographers leave everything, is evident, for the photography is perfect, there is gradation everywhere. The sight of this single photograph will open the eyes of every thoughtful person to the possibilities of photography; if more work like this was made, we should never hear of the reproach, "only a photograph." Mr. Bland has fifteen other works, all of which show the same reverence for what is beautiful and the patience which must accompany artistic feeling if good work is to be done.

Taking the works which were fortunate to be medalled first, we come according to the catalogue to No. 252, *A Chester Street*, by F. C. Smithard. Though this view is only about six inches by four, it has that most important quality, breadth; a mass of buildings on the right, their edges picturesquely broken against the sky beneath; to the left only a roadway showing tram lines, these lines leading into the picture. Though there are no figures walking about all over the road which make street views usually so unsatisfactory from a pictorial point of view, there is sufficient life to prevent the view appearing to be one of a deserted city. Mr. Smithard has other good work, notably No. 246, *The Woodside*. The next medalled print is No. 271, *Cromford Church and Bridge*, by George Walker. Though churches and bridges are not usually picturesque materials, there is enough of other material here in the shape of trees, water, fields, and sky to make a pleasing composition; the print is a platinotype of first-rate quality, we might say

the same of most of the other works of the local society. No. 285, *The Castle Gateway*, took a medal; if it had not done so, one of its companions, Nos. 282, 283, or 284, undoubtedly would have done. The next medalled exhibit is No. 288, *From the Storm come the Floods*, by Mrs. F. H. Gandy, which gives us a pleasing composition of woodland, water, and wet land. The next fortunate one is the work of Miss Evelyn Boden, F.R.P.S., No. 308, *A Little Dutch Mother*. Miss Boden aims even higher than most of her fellow-members. She has a soul above pretty bits, and, as her work shows, is already very successful at making pictorial portraits and groups; her medalled picture shows a young woman in a quaint Dutch head-dress bending over a cradle, making it ready for her babe, the treatment is simple and the picture is not spoilt by the addition of unnecessary accessories. Miss Boden has also a charming group, No. 309, of *Mrs. Gisborn and Children*. The expression on the boy's face in this is happy indeed. Her No. 298, *Christopher Wilson*, and her No. 311, *Zoe*, are both head and ears above most professional portraiture. Charles J. Allen gets a medal with No. 339, *Autumn*, a roadside view taken at just the right time of day, with atmospheric conditions all helping. A cottage and bankside in shadow coming against a lighter bend of the road, at a point where the lines of the road and trees lead to, arrests the eye at once. The remaining medal went to E. J. Highton's *Wrotham Broad*; other seven works by this exhibitor were all equally good.

Among the works which were very nearly of equal merit to the above-mentioned, if we except Miss Boden's works, we might say were of equal merit, we noticed No. 259, *Chee Tor*, by Thomas Walker, a platinum print, which reminded us of a well-printed carbon opal of a peep which might well stand for a view into Fairyland. Four works by Arthur J. Haynes, No. 267, looked almost too dark among so many sunny pictures. No. 268, *Underground Life—Loading Coal*, was certainly worth distinction. There are also two frames of Alpine views (No. 383), by Charles Bourdin, which were fine, except a few small figures with their eyes on the camera, well-nigh perfect. Space alone prevents us from mentioning more of the 200 excellent works of the Derby Society.

The ceremony of opening the Exhibition was performed by the Mayor of Derby (Alderman Ann), who invited a large company of guests to meet the members of the Derby Photographic Society at the Art Gallery on Tuesday evening. A letter of apology, regretting his inability to attend on account of a cold, was read from Captain Abney (the President of the Derby Society), by Mr. Crowther (the Curator). After the company present had spoken to their friends, and tried to get a peep at the pictures, they went, at the invitation of the Mayor and Mayoress, to take refreshment and cooler air in the lower gallery of the buildings.

## FOREIGN NEWS AND NOTES.

**Metol Developer.**—Dr. Haschek states that he has found that, when a metol developing cartridge is dissolved in hard water, development is much slower, the negatives are more brilliant and do not lose so much in the fixing bath, and that it is possible to thus correct over-exposure. Still better results, he says, are obtained by using lime water made in the ordinary way by adding quicklime to ordinary tap water, allowing to stand and then filtering.

**Light-sensitive Copper Salts.**—Schneeberger has made a series of experiments with copper salts as a substitute for silver. Cuprous iodide ( $\text{Cu}_2\text{I}_2$ ) damped with ammonia, was exposed to sunlight, half being covered over with an opaque card. The exposed part turned a deep blue, whilst the unexposed remained only a pale blue. When air was excluded from it, the exposed cuprous iodide blackened in proportion to the exposure, the unexposed part being white. An emulsion of the iodide was made in gelatine and sensitised in weak ammonia, and the air excluded by petroleum, and a plate coated with this was exposed whilst in the ammonia. It blackened on exposure, but again became white when placed in the dark. When the plate was taken out of the sensitiser, washed, and treated with dilute sulphuric acid, it developed up with a black colour. An emulsion of cuprous oxide ( $\text{Cu}_2\text{O}$ ) was also made and exposed, with exclusion of air, in water acidulated with sulphuric acid, and this also blackened, and kept that colour when washed and dried. In this case fixation was effected by means of dilute hydrochloric acid.

**A Film-flattener.**—Dr. Lenz-Bern states that films which have a tendency to curl are rendered quite flat, if they are laid face downwards in the middle of about sixteen sheets of smooth writing

paper, and then ironed with a flat iron, heated so that it will just sizzle when touched with the wet finger. It is stated that this makes the films lie absolutely flat during development and the subsequent operations, and that it has no prejudicial effect on the emulsion.

**Bromised Developing Agents.**—Dr. Lüppe Cramer one of the chemists in the laboratories of Schering's, has observed that the substitution of bromine or chlorine for a molecule of hydrogen in pyrogallol or hydroquinone gives some very valuable developing agents. Bromo-hydroquinone gives much softer and more harmonious negatives than hydroquinone with equal exposures, and this is particularly noticeable in the shadows with short exposures. Bromo-pyrogallol is one of the most rapid developers known. These bodies are easily prepared by adding to the mother-substance, hydroquinone for instance, dissolved in benzole, the necessary quantity of bromine also dissolved in benzole. The reaction takes place instantly, and hydrobromic acid is set free, and the solution is then evaporated to crystallisation. Chloro-hydroquinone is obtained by passing chlorine gas into the benzole solution. Bromo-hydroquinone has been introduced commercially under the name of adurol, which keeps for a very long time in a concentrated solution, and has no action on the fingers. The formula recommended is—

Water .....	200 parts.
Sodium sulphite .....	75 "
Potassium carbonate .....	150 "
Adurol .....	15 "

For use, dilute one part with from ten to fifteen parts of water.

**Three-colour Screens.**—In a little work recently published, entitled *La Photographie des Couleurs*, M. G. Naudet recommends the following solutions for bathing gelatinised glass for making screens for three-colour work:—

<b>1.—REDDISH-ORANGE SCREEN.</b>	
Bluish eosine .....	2 parts.
Naphthol yellow .....	1 "
Water .....	100 "
<b>2.—GREEN SCREEN.</b>	
Sulpho green S. ....	2 parts.
Naphthol yellow .....	2 "
Water .....	100 "
<b>3.—BLUE-VIOLET SCREEN.</b>	
Methylene blue .....	2 parts.
Paris violet .....	2 "
Water .....	100 "

For the yellow negative an ordinary Lumière plate, with No. 3 screen, should be used; for the red negative a Lumière A plate, with the green screen, should be used, and the increase in exposure is about five or six that for the yellow; for the blue a Lumière B plate, with the orange screen, should be used, and the increase of exposure is about fifteen to twenty times that for the yellow negative.

**Glass Tanks.**—For three-colour work it is customary to use either collodion or gelatine screens stained with the necessary dyes, but cells with parallel sides for holding solutions of the dyes are preferred by many. These cells are generally used immediately in front of or behind the lens, and it is then necessary that they should have optically polished sides which must be absolutely parallel to one another; the cost of such cells is very great, and to get over this difficulty D. Cellarius & Co., of Markirch have introduced cells of exactly the same size as the plate, and a set of three for 18×24 cm. plates costs only 5*frs.* They are placed just in front of the plate, where any slight variation from parallelism is of no moment.

#### PICTURE FRAMES.

[Abstract of a paper read before the Society of Arts by Mr. J. Hunter Donaldson.]

At the British Museum Dr. Murray kindly pointed out their oldest frame, of about the second or third century of our era; it is of a hard wood-like beech, of what we know as the "Oxford" pattern, with a marginal 1-inch flat, a groove to receive glass, and cord to suspend it by the corners. The panel had a portrait of encaustic, now nearly obliterated. I also saw an engraving of a Pompeian studio in which a lady artist is sitting, with a similar frame and portrait in it near her. We then went

to the finely preserved mummy from Hamara in the Fayoum, of a young woman once of much beauty, whose portrait on a 12×9 panel is at the head, with a framing of many folds of the cere cloth, which is ingeniously swathed so as to form a geometrical pattern all over the body. I am told that poor Egyptians, who could not afford to have such portraits painted expressly for their lost ones, used to buy, from stocks of ready-made portraits, such as most nearly resembled the deceased, and, when the swathing cloth decayed, such portraits were hung up as pictures. It was a custom of the Romans to have upon round or shield-shape wood portraits called "imagines" of their celebrated dead, modelled in coloured wax, to carry these in the funeral processions, and afterwards to suspend them in the houses.

We know that the ancients painted in every style of art, excelling in all, and, though Pliny says that "the greatest glory was obtained by easel pictures," he gives, as another reason for preferring them, the fact that paintings upon the actual walls cannot be saved in case of fire. We read that Cicero sent large sums of money to his friend Atticus, to buy pictures in Greece, for decorating his villa at Tusculum, and artists of distinction, like Polygnotus, must have been well aware of the importance and effect of suitable frames for their masterly works.

That no examples of beautiful ancient frames can now be found is not surprising, for we are told that the anti-pagan zeal of the early Christians led them to destroy everything they could which was pagan, however artistic; they used to put ropes round the marble necks of the almost divinely beautiful Apollos and Venuses, drag them into the open, try them in public like criminals, find them (of course) guilty, and then pound to dust statues by men whose names we reverence to-day. Thirteen hundred years later a religious zeal, not according to knowledge, led Cromwell's troopers to stable horses in Worcester Cathedral, whilst money was actually paid for the destruction of stained glass which we should now consider priceless. We do, however, owe to the "Protector" the purchase of Raphael's cartoons for the nation. I mention this, because it explains the reason why no frames have been handed down to us by which the subject can be illustrated.

Persons who will take the trouble to examine the frames used by the older English masters in oil and water colours will notice the poverty of design and the want of taste of most of them. This was felt so much by the leading artists in the sixties, that they were led to make great improvements, and, *à propos* of the common-place expression, "What a beautiful frame," uttered sometimes by those incapable of judging the merits of a picture, two articles appeared with illustrations in the *Architect*, exactly thirty years ago. These were written by Mr. Phené Spiers, Master of the Architectural Schools of the Royal Academy, himself an accomplished artist. He said, "In a frame lies a not inconsiderable portion of the completeness of a picture, and there are fortunately a few painters, Mr. Leighton notably among them, who have long recognised the fact that their powers of imagination and composition ought not to terminate with their canvas." Mr. Spiers ably criticises the frames in the Exhibition of the Academy in 1869, and we shall have details of those frames on our screen, with his remarks for our information.

Fourteen years ago, Mr. W. R. Lethaby, in an able paper, drew attention to the poverty of design in frames then exhibited, with some remarks to which I shall refer later. Before this time much attention had been given by foreign artists to their frames, which were not unfrequently designed under the influence of the best Italian period, some examples of which will be shown. We are justified in expecting that since the year 1869 an advance should be seen in the designs of frames, especially by our principal artists, and some of the more recent ones will be displayed. We may soon hope that, when the expression "What a beautiful frame" is heard, it may be found to proceed from a person whose cultivated taste and sense of beauty apply equally to the work of a true artist in his picture and in the frame he has designed for it.

I do not think it can be claimed for the frames in this year's Academy that they show any advance in design upon those of thirty years ago; some of the largest are defective in architectural detail, and some have large, busy, obtrusive mouldings close to the pictures; there is a noticeable display of old frames, for which there is now great demand, and for the first time we see a number of gilt frames toned almost to the colour of wood; some of the most grandiose lack the refinement of those of 1869, and, although there is undoubtedly more variety than formerly, there appears to be less purity of taste. The true relation of a frame to a picture has probably never yet been the subject of a lecture to students, and the very alphabet of this phase of art is unknown to thousands of them.

I will refer to four frames. I assume my hearers have been to the New Gallery and seen the work of Mr. Holman Hunt, *The Miracle of Sacred Fire*, in the Church of the Sepulchre at Jerusalem. Mr. Holman Hunt has put fourteen figures in groups on the frame with a seven-branch candlestick in the centre, and he has modelled all these in gesso; the frame is gilt and it requires toning, but apart from that it is interesting. The curious thing is this, he has made a pediment and rested it, without any frieze, on two pilasters. He has ignored, in the most flagrant manner, the ordinary principles of architecture. In many frames at the Academy there are obvious departures from the recognised principles which govern such work. My friend Mr. Chapman, from Paris, sent me the *Journal des Débats*, in which a picture by M. Roll is mentioned. The

subject of it is *Laying the First Stone of the Bridge of Alexander III. in Paris*. Mr. Michel, the critic, says:—

"The frame is a great low relief of wood with unequally projecting allegorical figures; below is a Siren advancing from the prow of a barque, the oars of which seem to come from the fore part of the picture above, rays of light appear to drive the nocturnal owl into a corner; on the sides are Peace, Abundance, and the Arts. This frame is a work of much pride to the distinguished artist designer."

The frame which can perhaps take the first prize for eccentricity, at all events in the English galleries, is the frame designed by Mr. R. Machell, R.B.A., for a picture called *Parisfal*. It must have been the subject of immense care and study by a highly intelligent man, and, no doubt, a true artist. I think you will agree, on looking carefully at it, that you would be sorry to live with it; and, secondly, that it is the most ambitious and least successful of frames this year. Incidents and characters of the subject are carved on the decorated frame, the centre being occupied by *Parisfal* raising the cup of the Holy Grail. In the picture of *Psyche's Bath* Lord Leighton has carried some details of the frame into his painting, but Mr. Machell has deliberately carried a large part of his subject into his frame; happily he is in this alone among English artists.

Not a little of the effect of picture frames depends on their being hung in a suitable light; a side light in a too projecting frame may cast an injurious shadow. Not long ago I saw an exquisitely carved frame and an equally beautiful panel in low relief, placed between the two windows of a room; the work cost 1200*l.*, and was practically lost for want of the side light which all such works should have. *Apropos* of this, we may recall the story of Douglas Jerrold and Albert Smith going to a picture gallery. On the stairs was a mirror, standing before which Albert Smith said, as he looked into the glass, "Ah, my boy, there's a picture!" "Yes," said Jerrold, "It wants hanging!" So, when we have a good picture in its proper frame, we must not forget that, as Jerrold said, it "wants hanging," and that carefully, in justice to the artist.

We must all have observed the great value of black in frames, especially in works of the Dutch and Spanish masters, sometimes with bands of tortoiseshell or fine lines of gold, with the varied and very characteristic wave mouldings which had their origin in Spain, and were adopted in Italy and Holland, the Dutch artists especially recognising the suitability of such framings for their paintings. Mr. Watts was among the first to observe this, but, curiously enough, the least happy use of black is perhaps in the large works of Mr. Watts at the Tate Gallery, where, at a little distance from them, broad bands of gold separate, instead of combining, the frames and pictures; this rarely occurs in the foreign examples. There are some good black and gold frames in our national galleries, and, as we know, in the mezzotints of Bartolozzi, Ward, and others. Black behind the glass, with gold lines and delicately moulded gilt frames, gives great charm to the works of their time. The neglect of proper framing by early and very able masters in water colour is surprising, in view of the seventeenth and eighteenth-century framing known by them, some of their finest works being injured by mean and meaningless surroundings. Men of acknowledged eminence, even in our own day, have not troubled themselves to consider the art of framing. It will, I think, be a matter of surprise that our noblest writer and critic, Mr. Ruskin, has not yet treated this subject in any of his beautiful works, and in many of those of authority upon painting which I have consulted no reference to frames is made. I do not absolutely affirm that Ruskin never made such a reference, but I have spent a whole day in going through his works, and I could not find a single reference to picture frames, which is a remarkable thing. The most noticeable of English designers of frames is Grinling Gibbons, born in London in the latter half of the seventeenth century. He was recommended by Evelyn to Charles II., who commissioned him to execute the ornamental carving for the Chapel at Windsor; he also did the foliage and festoons of the Choir of St. Paul's, the baptismal fonts in St. James's, Piccadilly, and works at Petworth, Burleigh, and Chatsworth, Hampton Court, &c. His talent was wasted in carving pens and feathers that were mistaken for real ones, flowers which used to move on their stems by the air, &c. We shall all agree probably in thinking such work, however full of loving labour, unsuitable for picture frames, to which it has been applied; the modern English housemaid would soon reduce much of it to matches. On my last visit to Florence I found a fine example of Gibbons' carving in a public museum; and a very ambitious work in South Kensington Museum is his *Stoning of St. Stephen*, probably copied from a painting. With some defects of perspective, it is not "the highest form of decorative design," in which Mr. Ruskin said, twenty years ago, "the English will never excel," but the rare sense of beauty in natural objects, the manipulative skill, and the tireless industry of Grinling Gibbons will always secure a place for him in the annals of art as our most original frame-maker.

As miniatures have always to be examined near to the eye, the effect of any mode of framing has not seriously to be considered; the oval form is obviously the best and most generally used, but the marked advance of this form of art has led to the adoption of square or oblong frames, generally in ornol; these are not, however, quite within the scope of our paper. In nearly all the oval frames there is a gold moulding round the picture, and that flat moulding is burnished highly, so that it is difficult to

look at the picture without the glitter of the thing coming to the eye, and it impairs the work. Now, whatever our objection may be on patriotic grounds to things "made in Germany," it is only just to admit that we owe to that country the introduction of highly finished frame mouldings in colour and gold, well suited for drawings, engravings, and the many and beautiful developments of photography; we have "bettered their instruction" with our framings in light and dark oak, walnut, and the shades of stained-green ash and oak which, with delicate gold lines, give such charm to these latter-day works.

The Americans, too, have entered this field, and now Messrs. Graves & Co., of Pall Mall, have frames of their make decorated in the "Adam" and "Empire," and other styles, with ornaments laid in gesso, on stained maple, walnut, oak, in tinted ivory, on neutral green, in bronze, on black, &c., of great variety and with harmonious effect. The style employed has perfect examples all around us, well known to art-lovers, but it has remained for our cousins to glean the field which was sown here and abroad a century ago, and the mezzotints, now so much sought, are charming in these surroundings. The Autotype Company have courteously sent some specimens of their less elaborate but highly artistic frames, and I cannot imagine any more suitable than these for the charming photographs with which they have made us so familiar.

[Having called attention to six frames, which Mr. Donaldson said were admirably adapted for the works they surrounded, he drew attention to some frames lent by Messrs. Goupil & Co., which he said represented what gilt frames French taste preferred. English frames designed by the artists were of more refined character, and had more appropriateness in connexion with the pictures. He next referred to some wood frames made in Florence, and drew particular attention to the extreme care taken to make the moulding intersect at the corners. After describing some slides, kindly lent by the authorities at South Kensington, Mr. Donaldson proceeded.]

The Florentine modern frames of carved wood, as you will see, have delicacy and beauty of detail; more elaborate and necessarily more expensive, they are of great technical merit, and are superior to any machine-made ones. Messrs. Goupil & Co., of Regent-street, have also lent gilt frames of marked character and high finish, with some others specially suitable for works in oil. Messrs. Gillow & Co., of Oxford-street, have kindly lent a variety of interesting and artistic frames of Italian and English make.

Now, a serious impediment to the art of frame-making is the rule of our Royal Academy not to admit any other than gilt frames. I do not know in whose prejudice or interest such a regulation originated, but I am confident of the support of able artists in saying that it should be rescinded, and that in doing so an impulse would be given to the production of truly artistic frames in gesso and in carved and decorated woods, such as we see abroad, and enormous additional effect would be secured for paintings at every yearly exhibition. I earnestly hope that the enlightened President will soon distinguish his reign by effecting this much-needed reform. The beautiful and allied arts of modelling in gesso, carving, inlaying, decorating, and enamelling would be stimulated, and public encouragement be quickly given to such a progressive measure. I invite the opinion of the Chairman with regard to that.

The material objection, I believe, is want of space; but, as Disraeli said, "a difficulty is a thing to be overcome," and, by excluding works of a secondary character, the experiment might be made of giving one room to some of the measureless variety of artistic frames other than gilt ones. I am fortified in this hope by the fact that for the first time we see in the Academy this year some frames with the gold toned down to almost the colour of wood in pictures on the lines. That is an enormous concession to the idea that frames might be improved and other than gilt. Oh for another Alfred Stevens who would, with proper encouragement, and with his unequalled genius, have created a school of artist framers as fine as any known to the world! We are, as Mr. Lethaby wrote in 1885, still waiting for an inspired artist worker, who must be free and with pride in what he creates; he will be, as Stevens was, familiar with the glorious old Italian methods, and will, I trust, be able to overcome the narrow-souled economy of even a minister of public works; then, indeed, it may be possible to read of an Academy picture some such notice as this:—

"The Florentine, Simoni Ceni, wrought the carving, and Gabriello Saracini gilded it, Spinello of Arezzo did the painting in 1385"

In lending these kakemonos and frames seen, Mr. Phené Spiers says:—

"It has struck me that a few words on the framing or mounting of drawings in Japan might not be without some interest, seeing that, until within the last few years, their methods have been carried on for centuries uninfluenced by the customs or practices of other nations."

"The Japanese have two methods: the kakemono or hanging picture, suspended temporarily only in the house or temple, and otherwise kept rolled up and preserved in the goldown, the fire-proof store-room; and the framed drawing hung up in the temple or carried about in processions. In the latter case the frame consists of a simple convex moulding, the width of which varies from half an inch to six or seven inches, according to the size of the picture, and this moulding is painted over with body colour with natural flowers (as in one of the examples shown), or with geometric patterns, leaving the

grain of the wood as a ground, or again with sprigs, leaves, and flowers modelled in gesso (as in a recent example). Sometimes the frame is coated over with black or green lacquer, on which geometrical patterns or sprigs of plants are cut through to show the white wood. The more elaborate frames are richly decorated with aventurine lacquer, with geometrical patterns in gold lacquer, and the angles and sometimes the longer sides are strengthened and decorated with brass plaques incised with ornament. The drawing in these cases comes close up to the frame, with a border of black or red lines to isolate it from the frame.

"The kakemono, or hanging picture, is mounted and decorated in a conventional manner, which is apparently always rigidly adhered to, and which seems to have existed for centuries. The drawing is mounted on linen or paper, with a margin of from two to four inches on each side, and from two to four feet top and bottom, the lower border being about half the depth of the upper border. At the top and bottom of the drawing is a narrow strip of damask, the upper twice the width of the lower; on each side of the drawing the 3-inch margin is covered with damask or silk of a different colour, the depth of the border above (6 to 8 inches) being about twice that of the lower border. Beyond this, above and below, covering the remainder of the mount, is a flowered silk or gold damask ground, with again double the depth at the top, a wood roll at the bottom, with ivory or polished ends, serving for rolling up the drawing; at the top is a semicircular roll with rings to suspend the kakemono. From this upper roll hang two strings or tapes of the same material and colour as that of the upper mount, the original object of which is not clear, probably it is a revival of a custom of tying up the kakemono, but they are never missing. The damask or silks which form the borders are, as a rule, of much greater value than the drawing, and it is probable that the professional mounter, or perhaps the owner of the drawing supplies these materials, which are the remnants of ancient dresses either belonging to the family or acquired from actors. The latter, as may be seen from the Japanese colour prints, wear the most gorgeous dresses, and, when done with, these would seem to be cut up and utilised, either for the purpose above stated, or as bags for precious pieces of lacquer, ancient tea jars, or masks. In the two examples exhibited one is a Buddhist kakemono, which was probably hung in a temple, the other has mounts of blue silk and ancient damask, which are really of much greater value than the drawing they frame, and of great beauty of colour."

A reference must now be made to "mounts," which are so extensively used; and of modern artists Sir Edward Burne-Jones is the one who has given most attention to them. Some of his designs are marvels of elaboration, and these recently seen at the Burlington Fine Arts Club were striking evidences of his fertility and refined taste. Ruskin says, "All noble ornament is the expression of man's delight in God's work," and "genius" has been defined as "an infinite capacity for taking trouble;" these Burne-Jones undoubtedly had. A short list of his frames, mounts, and grounds may be of use for future reference, and I therefore give the following examples:—

1. Inch plain oak frame, natural colour, mount deep cream, for sketch on lighter cream ground.
2. Same frame, mount warm stone, for drawing on soft red ground.
3. Same frame, flat reeded, mount 4-inch stone, coloured with  $\frac{1}{2}$ -inch gold band near the deep bevel,  $\frac{3}{4}$ -inch band of deeper stone colour next to gold, with black fine lines ruled on the gold and to outline the band.
4. Frame 1-inch reeded walnut, mount 4-inch grey-green,  $\frac{1}{2}$ -inch band of gold, 1-inch deeper grey-green, then another  $\frac{1}{2}$ -inch band of gold, lines of black on gold bands, for drawing in pencil on light cream colour.
5. A 2-inch reeded teak, coloured oak frame,  $\frac{3}{4}$ -inch gilt flat, for drawing on brown paper.
6. Same frame, flat of  $2\frac{1}{2}$ -inch light unvarnished oak, deep bevel, near which is a fine gold line, and another  $\frac{1}{2}$ -inch wide, outlined black, for a richly coloured sketch of King Cophetua.
7. One-and-a-half-inch flat black-polished frame, with a groove in centre, for chalk drawing on brown paper, very narrow gold flat.
8. Inch reeded light oak frame, mount light brown, very thick, and bevel cut so as to show various layers of the paper, for drawing on cream colour.
9. One-and-a-half-inch walnut frame, flat fluted, mount 4-inch warm stone colour, with deep plain line indented near bevel, for drawing on brick-red paper.
10. Frame  $1\frac{1}{2}$ -inch flat, with 3 grooves, green-gold, mount cream colour, band of  $\frac{1}{2}$ -inch green-gold near bevel, for etching in silver and gold on deep grey ground.
11. One-and-a-half-inch frame, black, slightly elliptic, with fine gold hollows on the edges, gilt narrow flat in some cases, and in others 4-inch gold mounts, where the print or drawing is strong in colour.
12. One-and-a-half-inch reeded walnut frame,  $\frac{1}{2}$ -inch mat flat, an oval inside of plain light oak, with fine gold hollow, forming sight, for portrait in black chalk on cream of light tone.

In conclusion, we may notice some changes in the last twenty years or so; a much more general employment of glass for oil paintings under

suitable conditions of light, and for their protection in our climate; this has to be sometimes done, as in the Tate Gallery, by an added moulding, not improving to the frame. Another is the more general practice of framing water-colour works as if they were in oil; this may properly be done when the colouring is of sufficient strength, and in all works there seems a tendency to employ broad bevels in place of the large gilt flats, and to allow the glass to cover them.

I submit for consideration some propositions arising from what has been said:—

1. That, whilst the frame should be designed with reference to the picture, and may, in some cases, have details emblematic of the subject, it should not attract undue attention, or be eccentric; rustic subjects should not be put in highly enriched frames.
2. That the enriched mouldings of frames should diminish in importance as they approach the picture.
3. That works, not of much strength in water colour, should have broader flats than those in oil, and not heavy gilt frames with much burnish.
4. That some pictures (like Lord Leighton's) are best without any burnish in the frames.
5. That landscape pictures, in most cases, are better in recessed than in projecting frames.
6. That the colour of a mount should not appear to blend with any part of the picture it surrounds.
7. That the gold in all frames should be toned to suit the pictures.
8. That some works have their best effect in carved wood, brown or black frames, with or without fine lines of gold added.
9. That strongly marked carved lines in frames, with corners and centres in high relief, are often injurious to the composition of line in the pictures.

#### THE ALIENATION OF WORKS OF ART AND THE RIGHT OF REPRODUCTION.

At the Third International Congress of Publishers, held in London last week, M. Lucien Layus, of Paris, read a paper on the right of reproduction and the property of drawings ordered for illustration work.

The artist who sells a picture or a design is presumed to have ceded only the material property of the work. He remains free to dispose as he thinks fit of the right of reproduction. The owner of the work who wishes to make use of the right of reproduction ought, therefore, to show proof of his having acquired this right from the artist or his assigns.

The Artistic Congress of Paris (1889), the Berne Conference (1889), the International Congress of Literary and Artistic Property, London (1890), Neuchâtel (1891), Milan (1892), Barcelona (1893), Dresden (1895), and Monaco (1897), have declared themselves of this opinion, and have expressed the wish to see all the countries of the Union agree among themselves to recognise that the alienation of a work of art does not in itself involve the transfer of the right of reproduction.

This principle has been generally acknowledged. In Great Britain and Columbia, however, a contrary principle is recognised. The English law of July 29, 1862, relating to works of art (Art. 1, par. 2), stipulates that the artist who sells his work does not retain the right of reproduction, unless he reserves it to himself by special agreement signed by the purchaser at the time of, or previous to, the sale.

The French law does not refer to this matter at all, but the Court of Cassation, in a judgment given by the united sections, on May 27, 1842, has decided that the alienation of a work of art conveys with it the full and absolute property of the thing sold with all rights and privileges appertaining thereto, including the right of reproduction.

M. Layus examined at length the serious disadvantages of the principle recognised by the English and Columbian laws and by the French jurisprudence, and moved the following resolution:—

"The Congress of Publishers expresses the wish that all the countries of the Union should agree to recognise that the alienation of a work of art should not by itself carry with it the transfer of the right of reproduction."

In the second part of his paper M. Layus considered the respective rights of the artist and of the publisher as regards the property of the original. He expressed the opinion that, unless otherwise stipulated, the material property should remain with the publisher who ordered and paid for this drawing.

The presumption is that the publisher has acquired both rights, since he ordered the drawing, that is to say, considered the eventuality of the possession of the work and of the right of production, and proposed a resolution to that effect.

The President remarked that in France drawings intended for publication remained the property of the publisher.

Mr. Bell, London, asked what would be the position of a man who desired an artist to produce the picture of a horse. Would he have the right to reproduce the picture, or would that right be reserved by the artist?

The President replied that this would depend entirely upon the agreement come to between the person ordering the picture and the artist. If the former stipulated that he wished to reserve the right of reproduction, then the artist could take no objection.

Mr. Bell remarked that the point did not seem to be quite clear. The Chairman's remarks only referred to cases where a distinct agreement had to be made. But what would be the standing of the parties where no special agreement existed?

Mr. Guinnis suggested that they should have a distinction between a picture which a person purchased and one which he ordered, as to the right of publication.

The President said that in France books were published for circulation amongst a limited number of people of a special design. The design was then sold, but it could not be used for a second publication unless there was a stipulation to that effect. A person who paid half-a-crown for a book could do what he liked with it, with the exception, of course, of republishing it. He considered that the same law should apply to a work of art.

Mr. Bell stated that in England, if a person purchased a picture, he could have no right to reproduce it; but, when a publisher ordered a picture to be drawn or painted it should be understood that the copyright went to the owner of the picture.

A resolution put by M. Lucien Layus, Paris, "That the Congress of Publishers express the wish that all the countries of the Union should agree to recognise that the alienation of a work of art should not by itself carry with it the transfer of the right of reproduction," was then put to the section and adopted, only four members voting against it. As a complement to the foregoing, it was decided that the expression of the opinion of that Congress should go forth that a drawing, ordered by a publisher from an artist for the illustration of a publication, should remain the property of the publisher unless otherwise stipulated.

#### ADUROL-HAUFF.

MESSRS. FUERST BROS. have sent us the following report on Adurol-Hauff by Dr. A. Bogisch: Under the name of Adurol, Messrs. J. Hauff & Co. and the Schering Chemical Works are bringing forward a new developer which, in spite of the increasing number of developers which have been introduced during the last decade, has a great amount of interest and will find favour even in the most conservative circles.

This new developer is really an old friend whose good and bad qualities are already known, but it is brought out in an improved form as the chloride and bromide substitute of the well-known hydroquinone (commonly called quinol).

Both the above firms have simultaneously discovered the great developing powers of adurol, and have resolved to combine in putting same on the market, being well protected by patents.

As regards the special qualities of adurol, the same show the advantages of hydroquinone in a greater degree without possessing its disadvantages. The disadvantages of hydroquinone generally are (1) the great amount of alkali required to increase its developing powers, (2) the very slow appearance of the image, and (3) the influence of low temperatures, which in the winter-time practically precludes its use; as the low temperature causes the image to appear slowly, hard development ensues, therefore hydroquinone is known as a "hard developer."

Of course, one of the advantages of hydroquinone is the good density which can be obtained with it, and which no other developer exceeds. As against the above disadvantages adurol has the following advantages:—

It requires only a very small quantity of alkali, in fact, the potash can almost be replaced by soda, the use of caustic alkali being entirely unnecessary. In spite of the small quantity of alkali, the image appears very much more quickly and, what is most important, a low temperature has practically no influence on the appearance of the image on development.

The most important property of adurol, however, is its power to give density, which is not attained even by hydroquinone and caustic alkali. Taking these properties into consideration, adurol is not what one would call a "rapid developer" like hydroquinone and caustic alkali (with the latter it only shares the power of giving density but not the rapid development), apart from the fact that adurol works free from fog until development is completed (which cannot be said of hydroquinone and caustic alkali). With adurol the image appears in about twenty seconds (that is, normal rapidity) and builds up gradually, and after about four minutes the necessary density in the high lights as well as in the details is obtained. The density does not therefore cover the high lights alone, but as development proceeds the details become dense in an equal manner, so that an harmonious, graduated and, we may say, more soft rather than hard negative is the result.

It is therefore clear that when using adurol the time of exposure, as against hydroquinone, can be reduced; in other words, even when exposures are made in very dull weather, in the studio, when snap-shots are taken, or when taking animated or X-ray photographs, adurol will answer for development where hydroquinone is absolutely useless. Nevertheless, hard negatives can be obtained with adurol, when required, by a judicious mixing of "neud solutions," and by the addition of bromide, or, where over-exposure has taken place, development can be easily regulated.

Bromide solution with adurol has a very effective retarding influence, although, perhaps, unusually large quantities may be necessary (as com-

pared with hydroquinone); that is however no fault, in fact we might say an advantage, because, by the addition of bromide, the used developer retains its developing properties much longer, and can be used oftener than is the case with hydroquinone. When experiments are made in this direction, it is astonishing what amount of work can be done with adurol. The solutions have extremely good keeping qualities, not only in the separate, but also in the mixed state. An adurol solution made on June 17, 1898, is to-day absolutely clear and possesses full developing powers.

The adurol manufactured by Messrs. Hauff is the chloride substitute—that of the Chemical Works, Schering, is the bromide substitute—of hydroquinone, but both are identical in their action.

The chloride substitute of hydroquinone is a white crystalline powder, which is much more soluble in water than hydroquinone.

The following is a formula which has been thoroughly tested, and can be recommended:—

#### 1. Adurol-potash developer.

A. Adurol .....	25 grammes, or 80 grains.
Sulphite of sodium, crystallised 200 .....	640 "
Water .....	1500 c. c. 10 ounces.
B. Potash carbonate .....	100 grammes, or 1 ounce.
Bromide of potassium .....	2½ " 12 grains.
Water .....	1000 c. c. 10 ounces.

#### 2. Adurol-soda developer.

A. Adurol .....	25 grammes, or 80 grains.
Sulphite of sodium, crystallised 200 .....	640 "
Water .....	1500 c. c. 10 ounces.
B. Soda carbonate, crystallised ...	350 grammes, or 3½ ounces.
Bromide of potassium .....	2½ " 12 grains.
Water .....	1000 c. c. 10 ounces.

With clear working negatives the bromide of potassium may be left out. For studio exposures take three parts A, two parts B.

For landscapes and snap-shots, take three parts A, two parts B, two parts water.

To make a concentrated single solution developer, the following formula is recommended:—

Adurol .....	25 grammes, or 80 grains.
Sulphite of sodium, crystallised 200 .....	640 "
Potash carbonate .....	100 " 320 "
Bromide of potassium .....	2½ " 12 "
Water .....	300 c. c. 2 ounces.

For studio work, take one part developer and five parts water.

For landscapes and snap-shots, take one part developer and seven-and-a-half parts water. The image appears, normally, in twenty seconds, and is completely developed in four or five minutes. For under-exposure, dilute the developer still further. For over-exposure, take a solution that has been already in use, or add to the fresh developer more bromide of potassium. If still greater density is required, same is obtained by the addition of more potash solution.

For developing bromide paper, take three parts A, two parts B, five parts water; or, one part concentrated developer and twelve parts water. For developing this paper, bromide of potassium may be dispensed with altogether.

#### HENDERSON'S FILM-HOLDER.

MR. J. HENDERSON, of Aberdeen, has devised a film-holder which is made of transparent celluloid or xylonite. The edges are turned over upon the surface of the holder, A (fig. 1), so that a photographic film slipped into the grooves formed by the edges being folded over is kept

flat during the manipulations. Longitudinal, cross and transverse indentations, a (fig. 1), are made in the body of the holder, to make it remain flat.

Being transparent, the films may be examined during manipulation without being removed from the holder.

The edges, A (fig. 1) are turned over by means of heat. The indentations are stamped in.

### "LIFTING" DISHES FOR DEVELOPMENT.

Mr. JAMES ROBINS has devised an arrangement which provides the dish with means whereby one end or side of the plate can be readily lifted clear of the liquid so that it can be taken hold of by the fingers without these coming in contact with the liquid.

Fig. 1 is a longitudinal mid-section of a dish, showing the photographic plate immersed in the liquid. Fig. 2 is a similar view, but with

FIG. 1.

FIG. 2.

one end of the plate raised. Fig. 3 is a plan, the plate being indicated in dots.

*a* is the dish, *b b* are the usual longitudinal depressions in the bottom of same, but these may be dispensed with in carrying out my invention. At one end of the dish is a gap or recess, in which is fitted a bent piece, *d*. This piece is pivoted at *e* between two lugs, *f f*, outside the gap, the space between these lugs being closed at the outer part by a back piece, *g*. *h* represents the photographic plate. When the plate is in the dish, the

FIG. 3.

bent pivoted piece, *d*, occupies the position seen in fig. 1, its inner end lying approximately flat under the end of the plate, *h*. When it is desired to remove the plate, the outer end of the bent piece, *d*, is pressed down by the finger, so as to cause the inner end to rise; the end of the plate, *h*, is thus lifted clear of the liquid, as seen in fig. 2.

It is obvious that other ways of lifting one end or side of the plate can be employed, but the particular way shown is simple and efficient.

The dishes may be made of xylonite or other suitable material, and the parts *f* and *g* may be moulded in one piece with the dish.

### THE JOLY PROCESS.

At the Photographic Club, on June 7, Mr. J. W. Mason showed some of the latest work by the Joly process of colour photography, for which Messrs. Newman & Guardia, of whom he was the representative, were the sole London agents. While, in many respects, the Joly process is similar to that of Ives, it differs in the important fact that there are no three negatives, three positives, three colour filters, &c., but that they remain the same as for ordinary monochrome work. The three colour filters of the process referred to above are, in the Joly process, ingeniously combined in one, the primaries, red, green, and violet, being ruled upon a gelatine base side by side to the number of 240 to the inch. Such a filter is placed in the camera in contact with the specially sensitive plate (the spectrum plate), and the result of exposure is that the

colours of the object photographed are recorded, after development, upon the plate in varying degrees of opacity, the negative being built up of fine lines as is the colour screen. From this negative a positive is made which is bound up in contact with a screen ruled in practically the same manner as the taking screen, care being taken that the red lines of the screen come in line with the particular parts of the positive which are a translation of the reds of the original. This slide is then shown on a screen by projection, and, if all has been done satisfactorily, a more or less truthful rendering is obtained.

Having briefly outlined the process and its principles, Mr. Mason showed one of the improved dark slides for providing contact between the screen and the plate. The screens are, by the nature of their production, costly items, and unless precautions are taken may be easily scratched and damaged. The new dark slide provides a place for the screen and ensures contact of the plate and the ruled surface without undue pressure or risk of injury. Another improvement has been in the reduction of the exposure, which has been reduced to as little as  $\frac{1}{10}$  of what was formerly considered necessary. It was originally stated that only slow plates were of use, and slow spectrum plates were employed, the duration of exposure being as much as two hours in certain cases. By means, however, of a special screen one is able to correct the light-values and use the lightning spectrum plate. The exposure should be gauged as correctly as possible, for upon this the correctness of the colour rendering depends. The Joly Company have recently prepared a piece of thin ruled gelatine, which is placed between the positive and the viewing screen, with the lines at right angles, the effect being to much diminish the mechanical appearance of the ruling upon the screen. It was shown that the task of correctly superimposing the screens and the positives was one of little difficulty, and of this the members were enabled to assure themselves.

Mr. E. J. Wall said that in his work with the Joly process he used collodion plates of his own manufacture. These required an exposure of ten minutes at two feet from two arc lamps, as against fifty minutes for the spectrum plate. He used an intercopter to correct for the colours, having to employ one which was almost pink on account of the excessive sensitiveness of the plate to the green. He was of opinion that the prominence of the red in one of the examples shown was due to errors of exposure. He remembered that in his early experiments he got nothing but red.

### "THE BRITISH JOURNAL OF PHOTOGRAPHY" AND THE LATE CRYSTAL PALACE EXHIBITION.

The following extracts tell their own story:—

"Cosmos" in THE BRITISH JOURNAL OF PHOTOGRAPHY, June 2, 1899:—

"Only twelve months ago the Crystal Palace Exhibition, the largest and most important undertaking ever ventured upon by the Royal or any other British photographic society, came to a successful end. It appears to have escaped notice during some recent celebrations that the Exhibition was originally suggested by this JOURNAL, and that for nearly two years before it was held the idea received in these pages an amount of unlagging and strenuous advocacy, without which it is doubtful if the Exhibition could have been brought to a successful issue. But such is the irony of Fate, all the credit goes elsewhere and so apparently do the thanks and recognitions of a less intangible kind."

From Photography (edited by Mr. Child Bayley) of June 8, 1899:—

"The claim recently made by a contemporary that the credit for the successful outcome of the big Exhibition at the Crystal Palace was due to it, and the ingenious complaint that it had not been paid in any way for its support, reminds us of the old trick which Huxley described as 'the carriage dog policy.' This consists in running before the coach of progress and barking loudly, turning round constantly to make sure which way the vehicle is going. Outside photographic journalism it is very common; we hope we are not going to see much of it inside also, particularly as the trick is so easy that it is not likely to bring much credit."

Extract from a letter from Mr. R. Child Bayley, formerly Assistant Secretary of the Royal Photographic Society:—

"12, Hanover-square, W.  
"May 31, 1898.

"I take this opportunity . . . to say how very deeply grateful I am, personally, for the kind and constant encouragement I have had from you before and during the C. P. show. Its success was due in no slight degree, I need hardly say, to the B. J., and, if the Society owes a debt of gratitude to the JOURNAL, I am sure its Assistant Secretary does to the Editor of the JOURNAL. Be sure I am always yours very gratefully,  
(Signed) "R. CHILD BAYLEY."

### THE TOTAL ECLIPSE OF THE SUN, MAY 1900.

We (*Nature*) have received the following circular from the U.S. Naval Observatory, Georgetown Heights, Washington, D.C., dated May 17.

"In anticipation of the total eclipse of the sun, May 28, 1900, the United States Navy Department has arranged with the Secretary of the Treasury to have admitted free of duty the instruments of foreign astronomers who may come to this country to observe the eclipse.

"To this end astronomers abroad who contemplate an expedition to

the United States are invited to notify the Superintendent of the Naval Observatory of the probable date of their arrival, with the name of the port at which they propose to disembark. The Navy Department will forward to the consuls of the different countries to which these observers belong, stationed at the ports in the United States at which the gentlemen shall arrive, a letter stating their purpose in travelling, which letter will be countersigned by the consul and presented to the collector at the port as a proof of their identity. Upon this the collector will extend all proper facilities for the speedy delivery of the instruments in question, free of duty and charges.

"The Superintendent of the Observatory will be glad to hear from each of the proposed expeditions, in order that he may render such assistance as lies in his power. The path of totality extends through a thickly settled portion of the country, including some principal cities. Facilities for transportation are excellent, but it is recommended that instruments be securely packed and marked 'delicate instruments—handle with care.' The climate at that season is warm. The chances for clear weather are good.

"Full information regarding routes of travel to proposed points, and other particulars, can best be obtained through consuls. Through the regular diplomatic channels notice should be conveyed to the local authorities of the city or town selected as a post of observation.

"This Observatory will issue a pamphlet of instructions, containing large scale maps showing path of totality. "C. H. DAVIS,  
"Captain, U.S.N., Superintendent."

## Our Editorial Table.

### "AGFA."

Sole Wholesale Agents, A. & M. Zimmermann, 9 and 10, St. Mary-at-Hill.

"AGFA" is a clear, colourless, one solution intensifier, stated to keep indefinitely, and merely requiring dilution for use. It immediately darkens the deposit, and in about three minutes intensification is complete, the plate being then washed from ten to fifteen minutes. Its other features are: It is not necessary to blacken the negative in a secondary solution, because there is no bleaching of the image; it does not produce a non-permanent stain; it is easy to judge when the necessary intensification is arrived at; the gradual building up of the image is plainly visible. AGFA produces an intensification free from grain.

### PLATONA (ILFORD PLATINUM PAPER).

Manufactured by the Britannia Works Company, Ilford, E.

We append the full instructions for Platona paper, a sample of which we received this week for trial:—

**Printing.**—Printing frame and pad should be quite dry. Print until all details are faintly visible. Examine in weak light only.

### DEVELOPING FORMULA. (Stock Solution.)

Potassium oxalate .....	2 ozs.
Potassium phosphate .....	1 oz.
Water .....	14 ozs.

If unable to obtain potassium phosphate, the sodium phosphate may be substituted, but the former is preferable. Dissolve the salts in hot water and allow to cool. This solution will keep indefinitely. For use take 1 part stock solution and 1 part water. Develop in weak artificial or diffused light, floating prints face downwards in the solution. The image does not lose in fixing.

### FIXING.

Pure hydrochloric acid .....	1 oz.
Water .....	80 ozs.

Immerse prints for about five minutes each in three consecutive baths and then give them a final washing in water for fifteen minutes.

The prints are then ready to be dried and mounted.

Platona paper must be always kept stored in the tubes in which it is bought, and if so kept will remain in good condition. The cap should be kept screwed up, so that the tube is air-tight. Do not screw it up too hard, or it may be difficult to remove.

The paper is sent out in tin tubes with screw tops, which make the receptacles perfectly light-tight and can be used for storage of the paper. In actual working we found the sample sent us yielded excellent results, the formulae employed being those above given. Platona paper is evidently the outcome of great chemical skill and experience, and we should imagine it would successfully appeal to thousands of photographers, who will appreciate it in the cheap and convenient form in which it is presented to them by the Britannia Works Company.

It is very late in the day to discuss the characteristic qualities of a platinum print, no matter by what particular process it is produced. Platinum printing, which twenty odd years ago was caviare to the general, now as well known as the albumen paper process. There is, however,

one feature of it upon which uninterrupted insistence is allowable: we allude to the property of permanence which platinum prints possess. Authorities are in agreement that in the whole range of photo-printing nothing stands a better chance of permanency than a carefully prepared platinum print, and on those grounds the process cannot possibly be robbed of its popularity. Albumen, gelatine, collodion, bromide, may rise or fall in public estimation; but it is doubtful if platinum will experience such fluctuations. Hence the move of the Britannia Works Company in taking up the process is a wise one and should be assured of success.

MESSRS. FUERST BROTHERS, of 17, Philpot-lane, E.C., send us a sample of Messrs. Lumière's new developer, hydramine. The properties of this developer, which is sent out in the form of fine white crystals, are set forth by Messrs. Lumière themselves in an interesting article which appeared in this JOURNAL of May 19 last.

### LIVING PICTURES: THEIR HISTORY, PHOTO-PRODUCTION, AND PRACTICAL WORKING.

By HENRY V. HOPWOOD. 275 pp., 242 illustrations. Price 2s. 6d.

London: Published by the Optician and Photographic Trades Review, 123-5, Fleet-street, E.C.

MR. HOPWOOD'S book on animated photography is, to our thinking, the most complete that has yet taken this fascinating branch of work for its subject. He has set about his task in a very painstaking manner. Opening with a brief study of the phenomena of persistence of vision, he discusses, at great length and by the aid of many illustrations, the illusion of motion produced by successive views of slightly varying diagrams. This chapter will be found of great service as an initiatory study to the main theme. The third chapter, on chrono-photography, takes the reader into a minute historical and theoretical examination of the successive steps which led to the transformation of the kinetoscope into the cinematograph of to-day, and the next section of the book is devoted to a description of the various forms of apparatus on the market at the present time. The practical production of the film negatives and positives is next dealt with. There are hints for exhibiting, a chronological digest of British patents since 1851, when Fox Talbot patented a device for making instantaneous pictures of moving objects, and the book concludes with a useful annotated bibliography. Mr. Hopwood appears to have spent very great care in the preparation of his volume, which, so far as we have been able to test it, is historically accurate; indeed, it is so good, full, and thorough, that it strikes us as deserving of immediately taking rank as the standard text-book of the subject. We must congratulate the author and our esteemed contemporary, the *Optician*, on having enriched the literature of photography with a volume which it is pleasant to read and profitable to study.

### CATALOGUES RECEIVED.

Marlow Brothers, 23-30, Constitution-hill, Birmingham.

BESIDES the "M. B." specialties in hand and stand cameras this catalogue, which extends to about 150 pages and has nearly 200 illustrations, deals with a large general stock of photographic apparatus and material. It is well printed and produced, and is sent to applicants for twopenny.

Levi, Jones, & Co., 29, Hoxton-square, N.

THIS catalogue, which has some 140 pages and scores of illustrations, is divided into sections, hand cameras occupying one; studio cameras, lenses, &c., another, and so on right through the field of photographic manufactures. The catalogue appeals to the trade, who should find it useful for reference.

## News and Notes.

MR. W. E. WOODBURY is to edit a projected American magazine, called *Photographic Life*.

ROYAL PHOTOGRAPHIC SOCIETY.—Technical Meeting, Tuesday, June 20, at 12 Hanover-square, at eight p.m. "Retouching," by Redmond Barrett.

THE address of Mr. James Bunce, optician and photographic dealer, has been changed from 21, Maitland-street to 93, Shandwick-place, Edinburgh.

MESSRS. BERGER & Co., manufacturers of photographic printing papers, of South Hill Works, Hampstead, London, announce that, in consequence of the increased prices of raw materials, on and after June 19, 1899, they will be compelled to advance the price of Luxia P.O.P. to 15s. per quire.

TECHNICAL EDUCATION.—The Local Government Board auditor recently gave an important decision disallowing School-board expenditure upon science and art education. The point arose through representatives of the London County Council taking exception to certain items of expenditure by the London School Board in technical or secondary education upon such lines as to compete injuriously with similar work in the Council's polytechnics and institutes in the same districts. The official auditor has now ruled that such expenditure by the School Board is illegal, and can only be carried through as financial aid from the County Council.

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—Continental Excursion Belgium, August 19 to 27.—Two leaders of this excursion are Messrs. William F. Slater and Walter D. Welford. Headquarters are at Brussels, and the fare, saloon, about 25s. Full programme will be issued in a week or so. Visitors will be welcome.

**PHOTOGRAPHIC CLUB.**—June 21, at eight o'clock, "Binocular Vision and the Stereoscope," by Mr. Thomas Badding. Visitors are admitted to the meetings of the Club on the personal introduction of a member, or by invitation cards, which the Hon. Secretary, Mr. W. R. Stretton, 4, Queen-street-place, E.C., will be pleased to forward on application.

It is with much pleasure that we note that, owing to the increase of business, Messrs. Newton, of Fleet street, have found it necessary to open fresh workshops, so they have taken a factory in Little James street, W.C., where they will manufacture their well-known induction coils and scientific instruments. The optical lanterns will continue to be made in the Fleet-street workshops, and the lantern slides at their works in Dalston and Islington.

A SUIT for 10,000 dollars damages has lately been decided against the old City of Brooklyn, on the ground that the city was responsible for the existence of a large show-case filled with photographers' exhibits, which fell from the second story of a building and caused serious injury to the plaintiff. The original suit was for 30,000 dollars, and was decided in favour of the city, but, on appeal, a new trial was ordered, which resulted in a verdict against the city for 10,000 dollars.

**STUDIO BOGEYS.**—At the annual meeting of the Royal Architectural Museum and Westminster School of Art last week Sir Wyke Bayliss warned the students against the bogeys which, he declared, haunted the studio. In the first place, there was the bogey of the commonplace, and he urged artists to remember that they should get more into their pictures than they could find in their paint boxes. All art worthy of the name began in paint and ended in passion. The artist should be not only a seer, but a revealer. Another bogey would fain persuade a man that he was an artist because he knew something about technique or had an appreciative mind for the beautiful. A third bogey harped on the word "pot-boiler," till many an artist lost interest in his work because he had come to regard it as purely commercial. There was nothing degrading about painting a picture for money, and most of the finest work in the world had been done with a keen eye to the financial result. In conclusion Sir Wyke urged that "the greatest bogey of all" was the one which persuaded the artist that "the golden age" of art had passed away, never to return.

**EMBEZZLEMENT.**—In the Edinburgh Police Court, before Sir James Russell, George Forbes, thirty-three, canvasser, 176, Causewayside, pleaded guilty to a charge of having, between the April 26 and May 16, stolen 4l. 12s. 6d. from Wood & Co., photographers, Princess street, Edinburgh. The prosecutor said that Forbes was employed by Wood & Co. to collect accounts and to get orders, on which he was paid commission. He sent a certain number of orders, which were afterwards found to have had no existence, and for which he got commission. He also collected over 3l., which was not handed over to Messrs. Wood. Mr. D. Murray, solicitor, said Forbes had been for some years in the employment of the firm. He was sent to open up a new district about West Calder, but, not being very successful, he became despondent and gave way to temptation. His employers had consented to take him back. The magistrate said this was a deliberate fraud by a confidential servant; but, as there was nothing against him previously, and as his employers were willing to take him back, he would give him the benefit of the First Offenders' Act, and put him under 5l. caution for two years.

MR. AND MRS. MONTAGUE COOPER were engaged to attend a *conversazione* held at Wellington College, Berks, on Saturday evening last, given by the Natural Science Department of that Institution. Mr. Cooper demonstrated to a large number of pupils and friends the value of the new printing papers, Velox, Gravura, and Dekko, which have lately been introduced, and are a great boon to amateur as well as professional photographers. By means of either of these papers prints can be exposed, developed, and finished in artificial or weak daylight without the necessity of a dark room, and a great many photographs can be thus obtained in a very short space of time, and also a choice of tones varying from red chalk, sepia, brown, and purple to black. Most successful results were obtained in all these colours. Mrs. Cooper was the centre of a crowded group during the whole evening, who watched with marked interest her skill in finishing photographs in water colours by means of a very clever instrument called the aerograph. This enables an artist, in an incredibly short time, to do what, with the ordinary artists' brushes, would take hours or even days to produce. Colours can be superimposed and very much softer and more even results obtained than with the brush. Altogether a very instructive and pleasant evening was passed, and at the close Mr. and Mrs. Cooper were warmly thanked for their attendance, and congratulated on the exhibition given.—*Somerset County Gazette*.

## Patent News.

The following applications for Patents were made between May 29 and June 2, 1899:—

**LOCKING ATTACHMENTS.**—No. 11,254. "Improvements in Locking Attachments for Photographic Apparatus." Complete specification. E. G. GOODSELL and W. B. HASKINS.

**REPRODUCTION PROCESSES.**—No. 11,255. "Improvements relating to Photoreproduction Processes and to Apparatus therefor." J. T. BENTLEY.

**COLOUR PHOTOGRAPHY.**—No. 11,466. "Improvements in the Method of and Means for Rendering Photographic and other Pictures of Objects Visible in their Natural or in other Colours." T. THORP.

**FOLDING CAMERAS.**—No. 11,472. "Improvements in Folding Cameras." J. E. THORNTON.

**CAMERAS.**—No. 11,475. "Improvements relating to Photographic Cameras." R. DRURY.

**PHOTO-PRINTING.**—No. 11,547. "Improvements in and relating to the Photo-printing of Drawings." Complete specification. A. SCHWARZ.

**CINEMATOPHONES.**—No. 11,550. "Improvements in Cinematophones and in the Production of Photographs therefor." Communicated by G. Bagrachow. W. P. THOMPSON.

**LIGHTING APPARATUS.**—No. 11,553. "Intense Lighting Apparatus for Instantaneous Photography, called a Relampago Guimaraes." Complete specification. J. F. GUIMARAES.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
19.....	South London .....	Exposure and Development. R. Child Bailey.
20.....	Gospel Oak .....	Toning Competition.
20.....	Hackney .....	A Few Remarks to Beginners. W. L. Barker.
20.....	Royal Photographic Society .....	Retouching. Redmond Barrett.
21.....	Photographic Club .....	Binocular Vision and the Stereoscope. Thomas Beddix.
22.....	London and Provincial .....	Open Night.—Nomination of Officers, Committee.
24.....	Croydon Microscopical .....	Excursion: Charlton. Leader, Dr. Parsons.
24.....	Hackney .....	Excursion: Mucking. Leader, W. Selfe.
24-26.....	Liverpool Amateur .....	Excursion: Windermere. Leader, Dr. Llew. Morgan.
24.....	Oldham .....	Excursion: Miller's Dale. Leader, Jas. Hall.
24.....	South London .....	Excursion: Theydon Bois. Leader, G. J. T. Walford.

### ROYAL PHOTOGRAPHIC SOCIETY.

JUNE 13.—Ordinary Meeting.—The Right Hon. the Earl of Crawford, K.T., F.R.S. (President), in the chair.

#### NEW MEMBERS AND FELLOWS, &c.

Seven new members were elected, four candidates were nominated, and three members were admitted as Fellows. The result of the election of Judges for the forthcoming Exhibition, as stated in our last issue, was formally announced.

#### ACETYLENE.

Professor VIVIAN B. LEWES read a paper on "Acetylene." Dealing first with the history of acetylene gas, he said that in 1836 Edmund Davy, nephew of Sir Humphry Davy, read a paper before the Dublin Royal Society, in which he stated that, in the course of some experiments in which he distilled tartaric acid, he obtained a residue which, when thrown into water, evolved a gas, that gas proving on analysis to be bicarbonate of hydrogen, and he went on to point out its properties, and concluded his paper by showing the marvellous illuminating power of the gas, and prognosticating that it would some day play a very important part in connexion with lighting. On reading Davy's paper, it was evident that very little advance had really been made since its date with regard to acetylene, and the facts which he put forward formed as good an epitome of the characteristics and properties of acetylene as could be compiled to-day. After Davy's time, many experiments were made, and in 1859 Berthelot commenced some researches which led to the discovery, in 1862, that acetylene could be built up from its constituents. This was followed by the discovery by Wohler, a great German chemist, that calcium carbide could be made in the electric furnace, and that it was decomposed by water with the evolution of acetylene gas. It was not, however, until 1892 that these experiments were put upon a commercial basis, when a Canadian experimentalist, named Wilson, found, quite by chance, that calcic carbide could be made directly from lime and charcoal in the electric furnace, the same result being arrived at a few months later by a celebrated French scientist as a step in some of the most beautiful researches ever made. At that time the amount of electricity necessary to make a pound of carbide was very high, but subsequent improvements had rendered it possible to make one ton per year with one electrical horse power. Professor Lewes next described the ingot process of making calcic carbide, in use in England and America, and the running process by which arrangements are now being made for the production of about 30,000 tons per annum on the Continent. He remarked that many people thought that if the carbide had a very fine crystalline surface it was perfectly pure, and that if it appeared like grey pig-iron it was impure, but he said that these differences were entirely dependent upon the manner in which it was cooled, and that the latter was often more satisfactory in use than the former. With regard to the precautions necessary in the storage of carbide, and which were sometimes thought to be vexatious, he said they were not unnecessary, and that in almost every country in the world where they were not insisted upon the history of acetylene had been marked by a considerable number of accidents. Turning to the subject of generators, the lecturer first showed the method which he described before the Society of Arts in 1895, the calcic carbide being placed in a perforated zinc cage and plunged into a cylinder filled with water, and the resulting gas being received in a floating bell; and he then classified and described the other methods which have been adopted for the generation of the gas, laying particular stress upon the importance of obviating undue heating in the generator as essential to the avoidance of danger. The following method

was given for ascertaining whether a generator was satisfactory: Put a small piece of carbide into water, and examine the residue; if the residue is white, or nearly white, the carbide is of good quality; then use some of the same carbide in the generator, and if, after the generation of acetylene is finished, the residual lime is white, there is no fault to find with the generator; but, if the residue is snuff-coloured, the temperature evolved by the decomposition of the calcic carbide was too high, and the generator is not a good one. After discussing the various forms of burners suitable for acetylene gas, the Professor alluded to its richness in actinic properties and its consequent value for photographic purposes, and said its cost would compare most favourably with that of other methods of artificial lighting, both for studio work and for printing purposes. He concluded by performing a pretty experiment to show that, when a light is applied to acetylene, it burns with a luminous and intensely smoky flame, and that, when a mixture of one volume of acetylene with one volume of air is ignited in a cylinder, a dull red flame runs down the cylinder, leaving behind a mass of soot, and throwing out a dense black smoke.

A discussion ensued, in which Messrs. CHAPMAN JONES, KROHNE, BOLAS, SPILLER, VEZEY, Sir H. T. WOOD, and the CHAIRMAN took part, and Mr. CLIFTON said he had found acetylene very useful both for projection purposes and in enlarging. It appeared, from the remarks of several speakers, that it was regarded as very necessary that the greatest care should be observed in generating and using the gas, but that, if due care was taken, no danger was to be apprehended from explosion or other causes.

#### COMING EVENTS.

Technical Meeting, June 20, a paper on "Retouching," by Mr. Raymond Barrett. After June 24 the Society's address will be 66, Russell-square, W.C., and on June 27 the President and Council will receive the members of the Society and of affiliated societies thereat, when it is hoped that as many as possible will take the opportunity of inspecting the spacious accommodation afforded by the new premises.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 8.—Mr. H. C. Rapson in the chair.

Mr. J. E. HODD showed an adaptation of the old plate-lifter or holder to present requirements in the shape of a celluloid dish with a plate-lifter combined. The device for raising the plate from the solution, without the necessity of bringing the fingers into contact with the developer, like the dish, was made of celluloid, and was freely, but securely, attached to the edge of the dish. It was also useful for maintaining a flow of solution over the plate, effected by alternately raising and lowering the plate on the lifter.

Mr. A. L. HENDERSON remarked that he had at one time tried to induce certain firms working in celluloid to put upon a market a series of graduated celluloid measures and other photographic accessories, but was disappointed at the lack of enterprise which he found. While British makers were practically stipulating for a good market, he saw Continental firms with commendable energy creating and absorbing the demand to themselves.

#### TONING BATHS.

Mr. Henderson passed round a print, of which the whites were perfectly pure, and the tone a purple one, to him very agreeable, yet there was not a particle of gold in the toning bath. He had been experimenting with various compositions in this end, and had arrived at a certain prescription, which he believed might be put upon the market in the form of a compound which required only dissolving in water to yield a combined toning and fixing bath, to which, while it might be added, gold was not a necessity. He found that it was as well to print a little farther than usual, on account of the greater tendency of the bath to bleach the print than was present with the methods now in vogue. Without specifying the ingredients and proportions altogether, he would say that the mixture included formates, lead and hypo in a certain combination. He was at present ascertaining whether the action of the hypo was impaired by its mixture with the other bodies, and proposed to test the fixing power of the bath upon bromide plates as against a pure hypo bath.

Mr. J. E. HODD said that, in his own practice, he invariably over-printed to that trifling degree which gave a slight veil over the whites, an extent which was hardly to be considered as over-printing at all. He did not find that anything but this slight veil was lost in the toning and fixing operations. As regards toning without gold, he had failed to detect any action in the case of the phosphate bath except in the presence of gold. Some papers, too, he added, refused to tone with phosphate altogether.

Mr. P. EVERITT believed that Dr. Just had asserted that a trace of copper in the toning bath was advantageous.

#### DEVELOPERS—MODERN versus OLD.

Mr. WALTER D. WELFORD opened a discussion upon the question of modern versus old developers by referring to the developer, pyro ammonia, which was taken as the standard in a paper to which he had recently listened. While admitting himself to be a pyro man, there were, at the same time, a few statements in this paper to which he took exception, and this, he thought, might be appropriately done in a discussion like the present. The author of the paper endeavoured to prove that pyro ammonia would do anything and everything that any of the modern developers would do, but in this he was not altogether in accord.

Modern developers, or some of them, had a different action to pyro in respect of prolonged development. Prolonged development with pyro resulted in an intense building up of density on the high lights out of proportion to the shadows. Metol, amidol, and other of the modern developers did not do so, but tended to a more proportionate action, so that a print from such a negative would show a truer scale of gradation than a pyro negative with this prolonged development. There was consequently something to be said in favour of the modern developer and against pyro in this respect. As regards the power with pyro and ammonia of altering the developing solution, any one who had used the developer at all would know that a very little additional ammonia introduced fog very rapidly. Not so with the modern developer. The amount of accelerator could be much increased without risk of fogging

the plate. In conclusion, Mr. Welford thought that modern developers undoubtedly gave one or two advantages in certain directions over pyro.

Mr. A. MACKIE asked whether, in asserting that a small increase of the ammonia with pyro gave fog, whereas with modern developers the accelerator could be largely increased without, the last speaker was referring to the carbonates of the alkalis in the latter case.

Mr. WELFORD replied that he did, the carbonates being generally employed.

Mr. MACKIE said that, if Mr. Welford had increased with the ammonia the restrainer, he would have found that a sound plate would stand a considerable amount of ammonia.

Mr. EVERITT thought that, in a comparison such as this, similar alkalies should have been used.

Mr. WELFORD said he used pyro soda himself, but took for comparison the pyro-ammonia standard in the paper to which he referred at the commencement.

Mr. MACKIE said in the old days the bromide and the ammonia were mixed together, and one could use an enormous quantity of it.

Mr. FRESHWATER kept the bromide with the ammonia when he used the pyro-ammonia developer. This was his favourite developer, but the difficulty of keeping the ammonia in condition had induced him to use the pyro-soda formula of late. He had found no great obstacle to the increase of the ammonia on occasion, and did not get green fog as a result.

Mr. WELFORD asked whether anybody believed it possible to get out of an under-exposed plate with pyro ammonia as much detail as with one of the modern developers? Could one use as much of the accelerator with the pyro to push development as with the new reducing agents? He thought not, and in extreme cases would discard ammonia.

Mr. MACKIE held that much depended upon the plate. Some would stand a lot of ammonia safely. At the present day, however, he thought that in such cases he should use metol or amidol instead of pyro.

Mr. J. E. HODD agreed that one could not overdo the density with the modern developer easily. They went to a certain extent, after which, though one piled on the alkali to an alarming extent, there was really little difference. As a standard developer, he liked the pyro-potash developer; but, if he had any suspicion of under-exposure, he should fall back upon pyro metol. He was of opinion that ammonia was now so little recommended by makers on account of the high speeds to which plates had been pushed.

Mr. EVERITT held the question of what a developer would do largely a matter of preference, and what one did with it. The ultimate result was little different. For an under-exposed plate he usually took fresh pyro, bromide and ammonia, using warm water, which he thought was a matter of importance. The results by this were as good as anything to be done by the new developers.

There was a long discussion, in which several interesting points were touched upon in addition to those we have enumerated.

Gospel Oak Photographic Society.—May 6.—Mr. S. D. McKELLEN, of Messrs. McKellen, Limited, of Manchester, attended to explain the capabilities of the

#### CATHEDRAL HAND CAMERA.

Mr. McKellen said that a need had been felt for a magazine hand camera of sound construction, which should be very easy and certain in its action, which should be constructed of reliable materials, and which should be offered to the public at a price well under 5*l*. That this want was a real one he knew by experience, for it had often been said to him, when explaining the Infalible hand camera, which was made by his firm, and which he had brought before the members of the Gospel Oak Society on a previous occasion—it had often been said to him, "Yes, it's a very nice article, but the price is too high. Cannot you give us something, equally reliable, which will leave us some change out of a 5*l*. note?" As a reply to this query, his sons had invented, and his firm had manufactured and placed upon the market, the Cathedral hand camera. This camera was one which he could recommend to any one who wanted a magazine hand camera with a really reliable changing mechanism. As this camera has not been on the market a very considerable time, details as to its construction may not be devoid of interest to the readers of this JOURNAL. The body of the camera consists of two boxes, one sliding within the other. These are pulled apart as far as they will go, steadily, and without jerking, and then closed up again. This movement has taken the exposed plate which was nearest the lens, and carried it to the back, leaving plate No. 2 in position for exposure. This, with the exception of setting and releasing the shutter, are all the movements necessary for taking a photograph. The changing mechanism, which is extremely simple, is rather difficult to describe. The plates are held in sheaths, each of which has a small steel rod or wire fastened to the top, and projecting perhaps a quarter of an inch on each side. These are numbered from 1 to 12 on the back, and the body of the camera having been pulled apart and closed again as many times as may be necessary until the indicator shows the No. 12, the door at the back of the camera is opened, and the sheaths, which have been filled with plates, are placed inside in their proper order. The camera is now opened and closed, the figure 1 appears on the indicator, and the first plate is ready for exposure. What has happened is this: The pack of sheaths was fed from the back into the inner body, and the movement of pulling the camera apart and closing it again has brought into action a lever in the inner body, and this lever has raised the front sheath until the pins at the top are in a position to be engaged in two hooks which are affixed to the inside of the outer body, which is the correct position for exposure. The exposure of No. 1 having been made, one proceeds to make ready No. 2. On catching hold of the front of the camera, a catch is felt at the bottom. If this be pressed, the two bodies are disengaged, and can be pulled apart a certain distance. On this being done, the hooks which are attached to the inside of the outer body first lay hold of the pins, and, on continuing to pull the bodies further apart, the sheath, still held by the hooks, is carried over the top of the remaining sheaths, and left swinging at the rear. The camera now being closed, the sheath is disengaged from the

hooks, and has taken the position previously occupied by No. 12, the hooks travelling forward until they resume their position, ready to engage the pins of No. 2 sheath, as described in the case of sheath No. 1. By this means it is possible to expose any given plate of the series. We will suppose that sheaths Nos. 1 and 2 carry exposed plates, that No. 3 is in position ready for exposure, but that it is desired to use a special plate, which our note-book tells us is carried in sheath No. 9. All that is necessary is to change (without exposing, of course) the sheaths numbered 3, 4, 5, 6, 7, and 8, by pulling the bodies apart and closing them again in the manner above described, until the indicator shows that No. 9 is in position. After exposure, the fact that No. 9 is exposed is recorded in the note-book, and the changing operation is continued until No. 3 is again in front of the lens, and, when No. 9 is reached again, it is passed over, and No. 10 brought to the front. By this simple means it is possible to load the camera with an assortment of plates, any one of which may be used without the necessity of waiting until those in front of it have been exposed, as is customary with a magazine hand camera of the ordinary type. When the camera is drawn apart for the purpose of changing the plate, two hooks at the side of the inner body spring out and prevent the other sheaths from being disturbed, but these hooks are automatically moved away, leaving the sheath which has been brought from the front to be pressed close against its fellows by a spring attached to the back door. The hooks are also out of the way when the camera is closed, so that they do not prevent the sheaths being fed into the back when it is necessary to reload the camera. The Cathedral is made in two qualities—A, fitted with a snap-shot roller-blind shutter, and B, which is fitted with a new roller-blind shutter, which has some novel points. First, as to price, it is cheaper than most others on the market. Second, in addition to the familiar movement for giving ordinary time exposure, by means of which the shutter remains open so long as the pressure on the ball is maintained, there is in this new shutter also a third notch, and, the lever being moved over to this and the shutter shut, a slight pressure on the ball opens the shutter, which remains open until the ball is again pressed. Thus for long exposures it is not necessary to keep the ball deflated the whole time. The camera is provided with two accurately set ground-glass finders, bushes for affixing to a tripod for time exposures, of which a very excellent pattern was shown by Mr. McKellen, made by his firm, and a first-class rapid rectilinear lens of about average focal length. Focussing is done by means of a small lever projecting just below the lens aperture, and moving over a scale, the accuracy of which may be depended upon. If desired, the camera may be fitted with the McKellen-Heywood finder, which has previously been described.

**Edinburgh Photographic Society.**—At the Annual Meeting of the Edinburgh Photographic Society, held in the rooms, 38, Castle-street, Mr. A. Eddington (the President) in moving the adoption of the report, stated that the Society had had a most successful season. The membership had been increased from 456 to 500, which was the largest membership the Society had yet had, while the surplus of assets over liabilities had been increased by a sum of no less than over 113l. That, he considered, showed a rate of progress of which the Society had every reason to be proud. The following elections then took place:—*Hon. Presidents:* Messrs. H. J. Blanc, R.S.A., J. C. Oliphant, M.A., and John Stewart Smith.—*President:* Mr. A. Eddington.—*Vice Presidents:* Mr. James Hay and Dr. Scott Lauder, R.N.—*Treasurer:* Mr. George Cleland.—*Curator:* Mr. John Anderson.—*Secretary:* Mr. J. S. McCulloch, W.S. Mr. J. B. Johnston was elected to a seat on the Council, and Messrs. James Aytton, S.S.C., and D. N. Cotton, C.A., were elected auditors. Votes of thanks to the Council and auditors for their services during the year were accorded.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITOR, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPH REGISTERED:—

A. Whittaker, Birchwood, 313a, Norwood-road, Herne Hill, S.E.—Photograph of Cinder Hill Colliery, Nottingham.

DENTROSE; REX, AND OTHERS.—In our next.

P. R. S.—Many thanks.

R. A. BEEMAN.—We do not recollect seeing mention of the idea, which is quite feasible. You would require a very long exposure.

COLLOTYPE.—T. O'CONNOR. The fumes from a paraffin stove will not be harmful in the drying box for collotype plates. Those from gas would be detrimental.

J. R. (Scarborough).—Many thanks for your letter. We must adhere to our opinion, which was founded on long experience. The specimens you sent were all good, and some were exceedingly fine.

LIGHT FOR STUDIO; EAST LIGHT.—An east light is not quite so convenient to work as a north-east or a north light, but equally as good portraits can be done in an east light. If the premises are eligible, from a business point of view, we should say close with the opportunity. See leading article in next week's issue.

**BACKING PLATES.**—S. L. Had you applied the backing according to the instructions issued with it, you would have experienced no trouble. Applied as you have done it, and with your modification of the material itself, we are not at all surprised at the result.

**METHYLATED SPIRIT.**—VICTOR W. Methylated spirit can still be had without the addition of mineral spirit, such as used to be easily obtainable, but you will have to get a licence from the excise authorities, easily obtainable, and then purchase in quantities of not less than five gallons. No charge is made for the licence.

**CHRISTIAN** asks: "What is the English law with regard to the closing of shops and business houses on Sunday, and how does it affect a photographic business?"—In reply: We believe an Act of Charles the Second can be set in force against the photographer trading on Sunday; but we do not think any magistrate would convict.

**WAXING SOLUTION FOR CARBON PRINTING.**—S. BIGOOD writes: "I have made a solution of wax and resin, as given in the ALMANAC for flexible support, but the whole of the wax does not dissolve, and the solution is turbid. Is that as it should be?"—Yes. Bees'-wax and turpentine do not form a clear solution, but the turbidity may be disregarded if pure bees'-wax be used. Rub the solution well on with the flannel and then polish with another piece, and all will go well.

**TAX ON VEHICLE.**—TRAP says: "I have a horse and trap which I have to have specially for business purposes, and I cannot do without them. Occasionally, on a Sunday, I take a drive out with my family, and now I am taxed for the thing. I have explained to the tax-collector that I must have the trap—a small wagonette—for the business, but he says that, as it is used for pleasure purposes, I must pay."—Yes, we surmise you must, inasmuch as the horse and vehicle are not used exclusively for business purposes.

**PHOTOGRAPHURE. SIGMA.**—We are quite familiar with the photographure named and there is, as you say, a considerable amount of hand work upon it. We have never heard that the firm who used it profess that any of their plates are untouched by hand, or indeed that any of the foreign houses, or English ones, that issue photographures profess that their plates are free from hand work. Some plates require more work than others, and the producers put as much upon them as they think necessary to obtain a successful result; the end justifies the means.

**FADING PRINT.**—W. W. H. writes: "By a separate post I send you a couple of 12 x 10 unmounted prints that were, with a number of others, printed for me by a trade firm less than two years ago, all of which have turned yellow like those. The firm say they cannot guarantee permanent prints, as all silver prints fade, and these were all right when they left their hands. But surely prints should not get in this state in so short a time. Yet the firm repudiate all responsibility in the matter. Have I no remedy?"—We cannot say. Less than two years for the prints to become in the state these are seems a very short time. The remedy, if any, is in the County Court. The prints are returned as desired.

**DEVELOPING FERROTYPE PLATES.**—FERROTYPE says: "I have been using some dry ferrotype plates for outdoor portraits, and find when I am developing that a scum comes up all over the plate, whether under or over-exposed, and which I can remove by applying tongue to it, but as it sometimes scratches the plate, owing to the film being wet, and not at all a pleasant practice, I should be pleased if you could tell me of a preventative or cure chemical, or otherwise?"—We should surmise that the scum is caused by some impurity in the developer. Personally we have had but little practical experience with ferrotype dry plates, therefore we suggest that you write to the maker of those you are using; he no doubt will tell you a remedy.

**OBSTRUCTING LIGHT.**—H. A. H. writes: "My studio is built out from the back of the house, and is for the most part a brick and glass structure. It was put up in 1874, and now the owner of the house next door, who has only had the place a year or two, is building a high warehouse, which will stop off all my light on one side of the studio. I have protested to him, but he says he can put up anything he likes on his own premises; but can he do so if he stops off my light?"—He can put up anything he likes on his premises, but not if he obstructs your "ancient lights." If the studio was built in 1874 it enjoys "ancient lights," and you can obtain an injunction to restrain his obstructing them—and lose no time in obtaining it.

**QUICK LENS WANTED.**—F. STONE says: "I want, if possible, to get a very rapid lens—more rapid than any of the f-5.6's. I only want to cover a plate about two inches square, but I want the image perfectly sharp, so that it can be enlarged several diameters. The pictures I want specially will have to be taken where the light is not by any means good. Can you advise me?"—The most rapid lens is what is known as the "baby lens." It is of the Petzval form, and has an aperture of about f-3; but, of course, at that aperture it has but little "depth of focus." What we should think would best suit would be one of the old rapid stereo lenses. They would cover the size well, and have an aperture of about f-4, consequently they are of double the rapidity of the f-5.6 lenses.

**RESIDUES.**—E. KRAUSE says: "I have got eighty-five ounces of silver dust which I should like to melt down in a crucible, but I do not know how to proceed. Could you kindly advise me how to do it?"—By "silver dust" we presume ordinary residue in the state of powder is meant. If so, mix the residue with an equal weight of a mixture, in equal parts, of carbonate of potash and carbonate of soda. Fill a "skittle pot," crucible about three-fourths full with the mixture, and put into the melting furnace. Apply the heat gently at first, and, after the contents of the crucible have been boiling some time, make up the fire, and increase the heat till the contents of the pot acquires a somewhat quiescent appearance; then remove. Unless you have a properly constructed furnace, you will do better to send the residues to a refiner.

## EX CATHEDRA

ON Monday last, the Select Committee of the House of Lords on the Copyright Bills now before the House met under the Chairmanship of Lord Monkswell. Amongst the witnesses was Mr. Gerald Robinson, President of the Society of Mezzotint Engravers, who stated that his Society was opposed to the principle of the Bill altogether, because it deprived the engraver of any status, by putting him on a level with the process-worker. He insisted that the three branches of work, engraving, process, and photography, should be treated separately, and that engravings should come under the head of original works of art, and be given a longer period of copyright, and that it should be a penal offence to pass off process work as engraving. Another witness, Mr. Edward Cutler, Q.C., after pointing out some curious anomalies in the Bill, as regards the qualification of locality, remarked that the tendency of legislation on the subject of artistic copyright seemed to make a dead set against photographers, which was unjust and unreasonable, especially considering the great progress that had been made in photography in late years.

MR. CUTLER'S valuable evidence was supplemented by that of Mr. Bulmer Howell, solicitor of the Photographic Copyright Union, who said that the proposed Bill differed in many respects from Lord Herschell's Bill of last year, and that every difference was detrimental to photography. In Lord Herschell's Bill all artistic works were placed on the same level, but the present Bill would draw a distinction between the various classes of works. Thus photographs were, in regard to copyright, to be degraded below some forms of process reproduction, which were only rendered possible by means of photography. Again, to put photographers under the obligation of registering would be, in Mr. Howell's opinion, a hardship involving much trouble and expense.

\* \* \*

IT will be seen by a letter in our Correspondence columns that the Royal Photographic Society convened a meeting for Wednesday night last, with the object of getting up a protest against the intention of the Bill to remove photography from classification among the fine arts. In our article on the subject last week we pointed out that the present time could hardly be regarded as opportune for altering the classification, seeing that, after a lapse of thirty-seven years, the claim of photography to be considered a fine art for legislative purposes was considerably stronger than at the date when the existing Act was passed. The agitation against the Bill as it affects the interests of photography and photographers is growing so strong that we may hope it will have the effect of inducing the Lords to modify the measure in the directions which we indicated last week. On at least half a dozen occasions in the past two months we have touched upon the various obnoxious clauses of the Bill, so that it is not necessary for us again to bring them to the notice of our readers.

\* \* \*

THE new "dry" stripping film of Messrs. Wellington & Ward, of Elstree, is, we are informed, ready for introduction, but some delay must necessarily elapse before it reaches the hands of photographers. It seems that, in what to outsiders may appear as the comparatively small matter of the spool, an unlooked-for difficulty has been met with, namely, that of its manufacture. Such a simple-looking piece of apparatus as a spool might not look to outsiders as hard to obtain quickly

and in large quantities, but this, however, is the fact, and Messrs. Wellington & Ward are therefore obliged to wait until they have an accumulation of several thousands of these spools before they can issue their stripping film in order to cope with the large demand that is waiting to be satisfied.

\* \* \*

MR. E. SENIOR, the teacher of photography at the Birkbeck Institution and the Battersea Polytechnic, is so far the only English experimentalist who has succeeded in producing good results by the Lippmann interferential process of colour photography. Last year he showed us some very good reproductions of silk ribbons, the colours of which with one or two exceptions were rendered with striking fidelity and vividness. A few days since Mr. Senior laid before us some of his latest results. These were half a dozen photographs of the spectrum which Captain Abney has pronounced difficult to excel. Looked at unbacked and with very slight obliquity, the colour bands are strikingly bright—indeed, we have not seen more beautiful results by the Lippmann process than those which Mr. Senior showed us. It is a pity that there are not amongst us more experimentalists of this kind who will take up a process and work it thoroughly from start to finish with a view of ascertaining its possibilities. We wish Mr. Senior success in any further work he may take up. The fact that he was able to produce half a dozen copies of the spectrum of equal brilliancy is the first evidence we have had that the Lippmann process can be comparatively easily made to yield duplicated results.

\* \* \*

THE Florence International Photographic Exhibition closed recently. We learn that the Invitation Section of British Pictorial Photography excited the greatest admiration of the visitors. To those photographers whose works have been sold cheques have been sent. Promptitude in this respect is not always a characteristic of exhibition executives. We trust this idea of international courtesies in the matter of exhibition photography will not be allowed to die out. It would be a good thing if here at home, from time to time, we could have representative collections of American, German, Italian, and French work for public exhibition. It is true that photographers who go to the Royal Photographic and Salon Exhibitions are able to obtain an idea of what the position of pictorial photography in these countries is likely to be from the few examples that are sent to them; but comparatively large and representative collections have not yet been available for public display here. Besides the few foreign exhibitors with whose names we have become familiar in recent years, there may be many others, equally as skilful, who only need an invitation to let the British public have an opportunity of studying their productions.

\* \* \*

MANY of our readers will be sorry to learn that the retiring President of the Photographic Convention of the United Kingdom, the genial and large-hearted John Stuart, of Glasgow, has been ill with influenza and throat trouble. However, he is recovering, and writes us hopefully of being able to attend the Gloucester meeting and perform the ceremony of introducing his successor, Mr. Crooke. Mr. Stuart has recently been holding public one-man exhibitions of his photographic work at Helensburgh, Dumbarton, and Glasgow, which have been

largely attended by interested visitors. Some of the portrait and architectural work Mr. Stuart has lately produced is of the very highest quality and distinction, and we have no doubt that, in giving the non-photographic public of the "cultured" city of Glasgow an opportunity of studying the very latest phases of camera work, of which Mr. Stuart, with remarkable vigour and self-adaptability, has shown himself master, an agreeable material reward will follow such enterprise.

\* \* \*

ANOTHER old friend of this JOURNAL and large numbers of its readers was, we regret to say, recently taken ill. We allude to the popular and much-respected George Mason, of Glasgow, a past President of the Convention. We gather that some time since Mr. Mason was knocked down by a cab, and that he is still suffering from the effects of the accident. He is at present in his country quarters. We wish him a speedy recovery, and trust that he, too, will be well enough to get to Gloucester. A Convention would not be complete without the cheery presence of George Mason, who has so often been the life and soul of its proceedings, and, we hope, will fulfil a like agreeable office for many years to come.

\* \* \*

At the offices of our Paris contemporary, *Le Figaro*, 26, Rue Druot, M. L. Hanrlau is holding, between June 20 and July 8, an exhibition of photographs on what are described as new platinum and palladium papers which are manipulated without development—that is to say, the images are presumably obtained by printing-out.

\* \* Our leading article this week deals with the subject of "Studio Aspects," and points out that though north light studios may be the best for successful portraiture, yet good results may be obtained in studios having other aspects. This article may be commended to the notice of those who have recently written us on this subject.—The Article by "R.," an initial which conceals the identity of a high optical authority, gives a history of what, for convenience' sake, may be termed the use of the convertible system in photographic lenses. This history should be of interest just now when combinations of lenses giving a variety of foci are being used.—The article by M. Georges Fernau on "Speed Scales" includes a table of plate speeds according to Wynne's and Watkins' principles, and a comparative table of speed numbers between Wynne's and the Hurter & Driffield systems.—Among the other articles in the present number attention may be drawn to that headed "The Autumn Exhibitions." This gives intending exhibitors particulars as to dates, &c., of four important autumn Photographic Exhibitions.

#### STUDIO ASPECTS.

THERE appears to be a growing idea amongst some photographers of the present day that good portraits can only be taken in studios with a direct north light, or, at least, in those having a more or less northward aspect. This idea, we know, has deterred some from taking premises that would have been highly eligible, from a business point of view, simply because a studio could not be erected having this supposed imperative aspect. How this prevailing impression has, during the past few years, gained currency it is difficult to conceive, unless it be that, with the introduction of dry plates, a certain know-

ledge of photography and its simple manipulations are so easily acquired that many have entered its ranks who possess only a superficial acquaintance with the art. Now, as a matter of fact, lighting and posing the sitter are the chief things to be learnt in portrait photography, and knowledge and skill in that direction are what so many seem to lack. Here is an example amongst many that have of late come under our notice.

We remember that, in January last, a correspondent wrote asking advice through the Answers to Correspondents' columns. He said, in effect, that he wished to commence business on his own account, and had been offered premises in a good position, on lease, at a very moderate rental, but he could only get a south light. His actual query was, "Would you advise me, all other conditions being favourable, to refuse the offer on account of the light being south?" Our reply was that very successful portraits could be, and are, taken in studios with a south light, but that such studios are a little more troublesome to work at times than those having other aspects, adding that, if our correspondent was a skilful photographer, there was no reason why the premises, if otherwise suitable, should be rejected on account of the south aspect. A fortnight later we received a letter from another correspondent—see the Answers column of our issue for February 10—in which he says, "I really think you have made a mistake in advising a young man to undertake a studio built with a south light. I don't think it worth the candle to a professional. *An east or west light is quite bad enough to work, and only a professional can realise the fact.*" The part we have italicised, no doubt, amused many experienced photographers at the time.

A few weeks back we answered another correspondent thus: "The only advantage of a studio with a north light is that it is easier to work, and requires less skill on the part of the photographer; but a skilful photographer will get equally as good pictures in a studio with any other aspect," adding that "the results depend upon the artist rather than the aspect of the studio." Since then we have had a protest to this reply from another correspondent, thus confirming the idea, as we have just said which we know is held by some, that only the best results are obtainable in studios with a direct north light.

It is a fact that a studio with a direct north light is easier and more convenient to work, and requires less skill than one with any other aspect, simply because the light is more constant throughout the day, and as a result the blinds need be made but little use of; hence there becomes a monotony in the lighting, all sitters being dealt with very much alike, whether it is the best for them or not. We are now, of course, referring to unskilful workers who yet produce fair results. Next to a direct north light a north-east light is the easiest to work, then a north-west, and there is not much to choose between them. East and west lights are a little more difficult at certain times of the day; but those which require the greatest skill to deal with, owing to the light constantly varying throughout the day, are south-east, south-west, and due south, yet excellent portraits are taken daily in studios having these aspects. These latter, however, have, for the most part, been built, *per force*, because no other aspect was available.

It may, however, be mentioned that Mr. Valentine Blanchard worked for some years in a studio with a due south light, and in it he produced some of his finest work. His studio in Regent-street, for example, was on a corner building, and one side had a south light, and the other an east one. Yet he preferred the south for working, because he found it quicker,

particularly in winter, and that he could get a greater variety of effect than he could in the other. But, then, Mr. Blanchard was a skilful artist. That famous photographer, the late Adam Salomon, after his return to Paris after the Franco-German War, built his new studio with a southern aspect, though he had the choice of other aspects. Speaking to an old photographer on this topic, a few days ago, he told us that, during his thirty years' experience of professional portraiture, he had worked in studios lighted from most points of the compass, but he had never had the luxury of working in one with a northwardly aspect. At this season, when the sun is at about its zenith, it must shine on the studio at one part of the day, whatever its aspect—even if it is due north—unless, indeed, it is shielded by some high, near, adjacent building, or is shaded from the outside by a screen.

The prevailing idea with some seems to be that the background must always be in one fixed position and the camera in another, and in these positions they are used by the majority. The blinds are treated in much the same way by many modern workers in a north-lighted studio. Some years ago we sat for a portrait in a Continental studio. There blinds were not used. The lighting was controlled entirely by screens composed of two or more thicknesses of very open net, of a pale bluish tint, strained on light wooden frames that could be adjusted to any angle, on stands which could be easily moved, like the background, to any part of the room. This system of lighting was vended for a substantial fee in this country a few years ago as the "German system of lighting." The system is a most excellent one—more especially in studios with other than northerly light—but it is obvious that it involves a certain degree of skill and judgment to obtain the best effects and that is not possessed by all who practise photography; but in skilful hands this system is an immense power. Inexperienced workers, however, would probably get on better in the orthodox north-lighted studio and the usual set blinds. It may, in conclusion, be asked, if studios only with northerly lights were essential for the production of the best work, how many there would be in large towns, where space is limited and the exigencies of building acts prevail? Not a quarter, we suspect.

The object of this article is to dispel the idea that northerly lighted studios are imperative to successful portraiture, and to emphasise the fact that the quality of the work is dependent upon the skill of the photographer rather than the aspect of the studio, whatever that may be; also that eligible positions from a business point of view should not be rejected simply because a north light is not available. The aspect of the studio should really be a secondary consideration to the business position.

**Test for the Purity of Soda Carbonate.**—The great popularity of the soda-pyro developer we believe is partly due to the ease with which it is compounded, ordinary washing soda being the commonly selected form of the carbonate chosen. Even in this form it is most desirable to have crystals as pure as possible, and a method of testing as to the presence of the so-called bicarbonate will be useful (we must at the same time urge the desirability of crystals of as pure a form as possible, the purified carbonate of soda being a far preferable form). The test we refer to, devised by Herr Melchior Kubli, depends upon the fact that an aqueous solution of a quinine salt of a certain strength is not precipitated by ordinary (or "normal") carbonate of soda if the latter do not contain more than two per cent. of the bicarbonate (the "sodium hydrogen carbonate"). An aqueous solution of quinine hydrochlorate of 0.4 per cent. strength (about two and a half grains per

ounce) is made and kept away from light. A little of this solution is added to an equal bulk of a six per cent. solution (a little over twenty-six grains per ounce) of the suspected soda salt. The presence of over two per cent. of soda bicarbonate will produce a permanent cloudiness.

**Fluctuations in Prices.**—In a general way, photography has, for a number of years, been singularly free from those changes in prices of staple materials which so often occur to the upsetting of calculations and the disturbance of trade in many businesses. As a rule, any change has been uniformly in a downward direction, the most conspicuous exception having been a great rise in platinum a few years ago—a change that influenced the price of a well-known paper. Silver, the other chief staple, as every one is aware, has been steadily going down, till now its cost is less than half what it was in the memory of photographers still young. But there have lately been symptoms of prices in some direction having touched bottom. Thus, certain glass-manufacturers have met in conclave and announced that, in consequence of the continued rise in the price of labour and of fuel, they will, for the future, charge a higher rate. Then, again, possibly as a corollary to this, we hear of one manufacturer of plates and another of paper having found it necessary to put up the prices of one brand of their manufacture. Still at present photographers have not, in their scale of prices, come so low as to be influenced by the market-price of the materials they make use of, though, in the matter of process-work prices, the margin is perilously close.

**Heating of the Anti-cathode in Röntgen Ray Work.**—This effect is well known to workers with the Crookes tube, and is a very annoying one, as the current has to be stopped when the heating is excessive, as otherwise the platinum may become detached from its place. To avoid this heating, Mr. J. Macintyre, in a letter to *Nature*, describes the plan he has adopted to prevent the occurrence, the method being the outcome of many experimental trials. He writes: "It occurred to me that, if we could get a piece of platinum fused into the glass itself, to act as the anti-cathode, and placed opposite the cathode, this object might be attained. Such a tube, after many attempts, has at last been made, and, although the first experiments have only been successful in making small tubes, others of a larger size are at present being attempted. The advantage of this method will easily be seen, because the heating of the piece of platinum can be prevented by placing the whole tube in a cooling mixture or otherwise. These tubes are difficult to make at present, but I possess one which has retained its vacuum for some weeks."

**Solubility of Lime.**—Lime water, i.e., a solution of lime in water, has been suggested as the alkaline agent for some of the more modern developers, and we know that lithia, another metallic oxide, has most valuable properties for the same purpose. But the former oxide is but very slightly soluble, as will be seen from the following list, showing its solubility at various temperatures:—

Temperatures ..... 15° .. 20° .. 25° .. 30° .. 35° .. 40°

Parts of water needed

for one of lime.... 776 .. 813 .. 848 .. 885 .. 924 .. 960

It will thus be seen that the maximum amount of lime dissolved is a little under half a grain to the ounce. It will be noticed that the higher the temperature the less that goes into solution.

**A Big Balloon.**—We are promised, of course from the other side of the Atlantic, a big thing in aeronautics, balloons, about half the length of the *Great Eastern*, one time the largest ship afloat. These new balloons are to be run by the Aerial Navigation Company, of San Francisco, and, according to a telegram from Dalziel's Agency, this Company advertises that it will convey passengers from America to the Paris Exhibition in thirty hours. The number of the balloons in building is stated to be three, and they must be of a remarkably accommodating character to go half round the world and

arrive at the exact spot required. No doubt they will be well provided with cameras, &c., and very probably will have dark rooms attached. There may be a little difficulty about a sufficiency of washing water for the purpose, though possibly water ballast may be used in lieu of sand. By the bye, we believe that Herr André has not yet returned with his balloon and baggage, which was well provided with photographic impedimenta!

**More Disappearing London.**—*Appropos* of the London County Council and its work, it may be mentioned that, if its scheme for a new thoroughfare from the Strand to Holborn be carried out, it will involve the destruction of most of the houses of historical interest in Lincoln's Inn-fields, made famous by Dickens. If the L.C.C. have their way, in face of the opposition to it, the west side of Lincoln's Inn-fields will disappear, for the whole of the houses on that side are scheduled in the scheme. However, there is great opposition to the project at present. The whole of this immediate region and Clare Market has been termed "Dickens's Land," but slowly and surely it is disappearing under this improvement body, and, even now, there is not much left. Lincoln's Inn-fields, like some other of the old inns hereabout, are like 'oases in the desert' in busy London, but they will, we fear, soon become things of the past at the hands of the L.C.C. Therefore those who desire to secure photographic records of them should obtain them while the opportunity exists and before they pass into the hands of the "house-breaker" and bill-poster. Too often the destruction of ancient buildings is unknown to photographers till they are obscured by scaffolding and posters.

**A Picturesque Spot Threatened.**—Those of our readers who know the walk between Kew and Richmond, by the river, are familiar with the little stream known as the Ha-ha, which flows for about a mile between the old Deer Park and the Thames side, with its overhanging trees and shrubs. This little and picturesque stream the Office of Woods now propose to fill in, and thus one more beauty spot in the neighbourhood of London will be lost to the public. It has, from time to time, furnished much food for the camera, to which it lends itself admirably, more particularly for stereoscopic pictures. As a matter of course, the Town Council of Richmond are protesting, and at its meeting last week it was unanimously agreed that the filling up of this stream would amount to the destruction of one of the most beautiful scenic features of Richmond, and it thereupon appointed a deputation of protest to the Office of Woods. It is to be hoped that the protest will have the desired effect, for it would be an act of vandalism to destroy its beauty. It is, we believe, a quibble between the Office of Works and the Office of Woods as to which shall maintain the stream that has led to the proposal of the latter that it shall be filled in and so destroyed.

**The L.C.C. and Art.**—At the meeting, last week, of the London County Council it was moved by Mr. Granville-Smith that it be referred to the General Purposes Committee to consider and report as to the desirability of appointing a new standing Committee, to be called the "Art and History Committee," to which all questions of an artistic, archaeological, or historical character should be referred, so that the artistic claims or needs of the streets, buildings, monuments, antiquities, statues, and works of art in the metropolis may be fully considered." County Councils have often been taken to task by artists and others for the way they deal with what might be made really artistic without interfering with utility. It seems pretty clear that the London County Council have very little sympathy with art or kindred subjects, from the fact that the proposition to simply refer the question of the desirability of such a Committee to the General Purposes Committee was only carried by a very small majority. This does not look very promising for the report when made, if it be in favour of the appointment of an Art Committee. Of the desirability—nay, necessity—of such a body on the L.C.C. there is no question, if one may judge by what it has already done, and proposes to do, in the way of despoliation.

## ON SETS OF LENSES.

WHEN in 1839 Daguerre and his followers found out the slowness of the optical system then in use, it was of the highest importance for the development of the photographic art to improve on the lens and to provide a more rapid instrument, so that portrait photography might become possible. The want was so strongly felt that the "Société d'Encouragement pour l'Industrie nationale" in Paris put up this question for competition.

There was one way of accomplishing the task which was simple enough to practical opticians. Whereas the lens used by Daguerre, as constructed by Charles Chevalier, was a single landscape lens with the relative aperture  $f/14$ , it was possible, by combining two lenses, to reduce the focal length of the doublet and to increase the relative aperture. Charles Chevalier had made use of this principle some years before (1834), in constructing a new double objective for telescopes, and thus he

FIG. 1.—Charles Chevalier's Set as given in *Mélanges Photographiques*.

soon produced on the lines indicated above his photographic doublet, which consisted of a landscape lens, A, at the back of the tube, and an achromatised biconvex lens, B, in the front. This latter lens could be changed for another similarly constructed, of greater focal length, and thus one was able to use the three lenses in two different combinations, viz., the back lens combined with the front lens of less power as medium-focus doublet, and the back lens combined with the front lens of greater power as rapid short-focus doublet.

It does not appear, however, that Charles Chevalier advised his customers to use the back lens alone as a long-focus landscape lens. Very likely the rigid camera of his make did not allow of this application, which would be easy enough for a modern camera with considerable bellows extension.

As is easily understood, this arrangement of three lenses enabled the photographer to reproduce his subject from the same standpoint in two different sizes, and so we cannot be astonished that Charles Chevalier obtained the highest prize from the above-named society for his "Objectif à Verres combinés." This prize was a platinum medal, and it was awarded on account of the possibility the objective offered for altering the scale of reproduction.

Similar features are to be seen in A. Ross's Collen lens, made in 1841. The front lens, B, of this doublet could be removed, so that the photo-

FIG. 2.—A. Ross's Collen Lens as given in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, 1864, p. 329.

grapher was able to use the back lens, A, alone in case of a longer focus being required.

It was the common fault of these two early combinations, which were constructed on the sound idea of the set of lenses, that the spherical aberration was not corrected, and thus neither of them could resist the competition of the Petzval lens.

It is very curious to notice how far the destiny of this combination differed from the idea which its originator formed of it in the beginning. J. Petzval also tried at first to construct a set. The front lens, A, could be combined with either one or the other of two double uncemented back lenses, B of magnifying, and C of diminishing power. The combination, A B, was the world-wide known portrait objective brought out in the autumn of 1840, whereas A and C formed the now forgotten

"Orthoscopic," an objective which raised considerable excitement forty years ago. A B was the extremely rapid ( $f/3.4$ ) short-focus lens, A C

FIG. 3.—J. Petzval's Set as given in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, 1859, p. 3.

an objective of medium rapidity ( $f/8$ ) with an equivalent focus of about the (2.3 fold) length of the former.

The great difference between the two foregoing sets and that of J. Petzval consisted in the correction of the spherical aberration, and there can be no doubt that this set of three lenses (A, B, C) would have met with universal approval had they been brought on the market together. This was, however, not the case, the originators being dissatisfied with the performance of A C, and thus A B alone was advertised.

It is unnecessary to dwell on the properties of this splendid combination—there is no doubt it was the objective needed at that time, and thus the feeble growth of the idea of the set was checked, at least in England. A. Ross took up the Petzval form, and it was not till many years later that his son brought out a modified doublet again. In France, Charles Chevalier held firmly to his idea; he continued to sell his doublet, but even his energy could not prevent its gradually sinking into oblivion.

While these events were taking place in the large factories of A. Ross, Fr. Voigtländer, Charles Chevalier, and others, Thomas Davidson, an Edinburgh optician, took up the almost abandoned idea of the set. In the second volume of the *Photographic Journal* we find an article, "Lenses for General Purposes," by J. Brown, from which we cite the following:—

"I possess a portrait combination made by Mr. T. Davidson, optician, Castle Hill, Edinburgh. The front and back lenses are each cemented, thus having the fewest reflecting surfaces that a lens can have, and thus ensuring the least possible loss of light from reflection of surfaces. The outer lens is 14 inches focus, and the inner lens is 21 inches focus. Thus placed they are 6½ inches focus, and give a half-plate sized picture. They can be reversed in the tube, and give a longer focus, and of course produce a larger picture by being thus reversed; or, if need should be, the 14-inch focus lens can be used for views, &c., and gives a well-covered field and perfect 9 inches by 7 inches. The 21-inch lens, when used for views, gives a picture 15 × 12 inches. Here, sir, is a lens having a four fold use, each change working to the visual and actinic focus perfectly."

Leaving aside the mistake concerning the difference of the equivalent foci of the doublet, we find in this communication no description of the single lenses save that they were cemented; but it is very likely, as seen

FIG. 4.—T. Davidson's Objective, constructed according to J. Traill Taylor's *Optics*, p. 70.

from later articles by T. Davidson, that these single lenses were of the same construction as Charles Chevalier's landscape lenses, i.e., a biconcave or plano-concave flint lens cemented to a biconvex or plano-convex crown glass.

Supposing this to be correct, we are able to sum up as follows: In the early part of 1855 we find the first real set introduced by T. Davidson of Edinburgh. It seems to have consisted of two similar landscape lenses, which, when used separately, gave the longer foci and which could be

combined to a short-focus double objective. The principal progress was the similarity of the components, which, in the first place, ensured that every one of the single lenses could be equally well applied separately, and, in the second place, that a theoretically unlimited series of different single lenses could be selected to make the set all the more complete. It is obvious that with this composition the greatest number of possible combinations could be obtained; whereas, *f.i.*, the Chevalier set of three lenses gave at most three different foci (one single lens and two doublets) a set of the same number of similar lenses would be equal to six objectives, *i.e.*, three single lenses and three double combinations. Why this system was not accepted by a greater number of photographers I do not know. The late J. Traill Taylor in his *Optics of Photography*, speaking of T. Davidson's lenses, is of opinion that they were not rapid enough to compete with J. Petzval's portrait objective. This is certainly correct as far as portrait photography is concerned, but I do not think the entire matter can be explained in this way. At any rate the system became obsolete, and the new development of the old idea of the set was to take its departure from J. Petzval's portrait system.

It was in 1848 that the Petzval portrait lens was so mounted by Fr. Voigtländer that the front lens could be used, in a reversed position, as a single lens with stop in front. The available aperture was, according to our authority (A. Martin), only  $f/29$ . Thus the Petzval lens had acquired the character of the set again, but of course not nearly to the same excellence as originally intended by J. Petzval. Now, it was, as regards its qualities of a set, on the same level with A. Ross's Collen lens, *i.e.*, it could be used as a doublet, and one of its components as a single lens.

I am not aware whether this modification was adopted in England, but there is no doubt that efforts were made in this country to improve on the Petzval objective in the direction indicated above. Thus, F. Scott Archer, early in the fifties, recommended the putting in of a thin magnifying or diminishing lens between the two components, in order to shorten or to lengthen the equivalent focus of the combination. As regards the optical correction of the system so treated, this plan is certainly a decided drawback to the Petzval formula; but, if we intend to describe the development of the idea of the set, we have to mention it as the form which this idea took in the endeavour to modify the Petzval portrait combination to a set objective.

It is possible that for practical photographers the general applicability was of greater value than the excellence of the different combinations, and therefore we need not wonder that a great many of these sets were sold in England. Anybody interested in the different methods of accomplishing the modification referred to will find ample information in Jabez Hughes' able article, "On the Mechanical Adaptation of Portrait Lenses for View Purposes," published in THE BRITISH JOURNAL OF PHOTOGRAPHY, 1860, pp. 330-1. It may be mentioned here that these modifications on the Petzval lens, according to F. Scott Archer's ideas, were largely carried out, especially in France.

It does not appear that the original Petzval set, when brought out commercially in the year 1857, was very much used. A great rush was certainly made for the *orthoscopic*, for it was—without reason—reported to be free from distortion, and at that time the chief aim of the English and American opticians was to produce an objective free from distortion, regardless even of spherical correction. Thus the Petzval set was brought out too late, and, as far as I am aware, never met with the appreciation which the originator's undoubted skill in balancing the different errors justly deserved.

The above-mentioned efforts to construct an objective free from distortion produced in America the *ratio lens*, the invention of the optician C. B. Boyle. It was in 1863—taking his statement made four years later to be correct—that for the first time after T. Davidson we meet with an objective expressly described as made of two similar components symmetrically placed at proportionate distances from the stop, a combination we may properly call *hemi-symmetrical*, in order to distinguish it from symmetrical combinations in which both components are identical.

I am not aware whether C. B. Boyle advised the use of the components as single lenses or not, neither am I in the position to assert or to contradict a connexion between him and Joseph Zentmayer, the originator of the following set. This American optician worked out in 1865 a set consisting of six single unschismatic lenses:—

- I.  $f=5.333$  inches; II.  $f=8$  inches; III.  $f=12$  inches;  
IV.  $f=18$  „; V.  $f=27$  „; VI.  $f=40.5$  „

These single lenses were suitably mounted, so that each one of them

screwed into the tube was in its proper position to the stop. The combinations gave the following focal lengths:—

- I., II.  $f=3.35$  inches; II., III.  $f=5.333$  inches; IV., V.  $f=8$  inches;  
IV., V.  $f=12$  inches; V., VI.  $f=18$  inches.

Judging from these numbers, we do not think it likely that J. Zentmayer intended the use of the single lenses, because the foci of four of them were contained in the series of the focal lengths of the doublets, whereas the camera extension necessary for V. and VI. probably prevented the employment of these lenses.

Summing up the foregoing, we may remark that the practical execution of the idea of the set was developed in two directions; in the first place as an entirely unsymmetrical set mostly on the basis of the Petzval portrait objective according to the rules laid down by F. Scott Archer; in the second place as a symmetrical set as probably first intended and introduced by T. Davidson, of Edinburgh; later again, but only partially, by J. Zentmayer. Comparing the value of the two possibilities, we may justly remark, that the first is inferior to the second, especially as regards the possibility of using the components in the greatest number of combinations.

In the sixties we do not meet with the asymmetrical sets constructed on the Petzval objective; only in 1863 A. Davanne describes a set of nine lenses which contained the two components of Petzval's portrait lens; the other seven seem to have been similar and interchangeable.

Later on, in 1883, Thomas Funnell took up the idea of the asymmetrical set again in a somewhat interesting manner. His objective is similar to a certain extent to objectives constructed by J. T. Goddard, and consists of a cemented front combination and an open back combination. This latter is composed of a negative flint lens close to the stop and a plano-convex crown lens, A, at the end of the tube, which could be

FIG. 5.—T Funnell's Objective as given in THE BRITISH JOURNAL OF PHOTOGRAPHY, 1883, p. 238.

unscrewed and replaced by another crown lens of different focal length. It is easy to see that, in substituting divers single back lenses to the compound front and the dispersing lens in the middle, the equivalent focus of the different combinations will also vary. T. Funnell does not say anything about the accompanying alteration in the chromatic correction in the different combinations formed according to his idea, and perhaps—apparently not manufacturing the lens for sale—he overlooked the matter entirely.

In very recent times, Mr. H. Dennis Taylor seems to have taken up an analogous idea\* of substituting the back lens of a triplet by other single lenses of different focal lengths, and accomplishes at the same time the chromatic correction by using different glasses for the divers additional back lenses, so that the single lens of the least power is made of glass of the greatest dispersion.

Another revival of the unsymmetrical set was brought about by H. L. Aldis, of the firm J. H. Dallmeyer, Ltd., in the *Stigmatic*, Series II. This astigmatismally corrected objective can be divided into two dissimilar components which can be used separately as long-focus lenses.

The rest of this historical paper may be devoted to the development of the symmetrical set.

There is no doubt that the discovery of the *symmetrical (rectilinear)* very much facilitated the construction of symmetrical sets based on this type of construction. It seems that sets of similar lenses achromatised in T. Grubb's manner were largely produced, especially in France, and particularly in the time preceding the introduction of the new glasses. We find many advocates of this contrivance, and among them the late J. Traill Taylor; he frequently advised his readers to use the set, or the casket lenses, as he sometimes styled them, because they placed a great

\* THE BRITISH JOURNAL OF PHOTOGRAPHY, 1899, pp. 199, 200 (March 31).

power into the hands of the photographer. We must, however, admit that the back lens of a symmetrical (rectilinear) did not possess the highest degree of perfection, especially as regards the correction of the oblique pencils.

The decisive departure from this state of the matter was taken by Dr. P. Rudolph of Jena. After the definition of his principle for producing astigmatic correction together with flatness of field, he saw, 1891, the possibility of correcting a single lens for the oblique pencils. This construction, however, was replaced by another brought forward in 1895, as any one interested in this matter may see in this JOURNAL, 1894, p. 829. These lenses are manufactured and sold in England under the name of *convertible anastigmats*. The single lenses are corrected both spherically and astigmatically: two of them not too different as regards focal length form a doublet of considerable aperture (1:6.3 to 1:7.7).

Thus the old idea of T. Davidson is accomplished in a modern anastigmatic objective, which yields three objectives of different focal lengths and having the fewest reflecting surfaces possible. R.

### SPEED SCALES.

I HAVE seen with much pleasure in your number of the 5th ult. that Mr. Hett has taken up the subject of speed scales as being well worth the attention of scientific bodies, and of all photographers who have at heart to work on mathematical principles.

The importance I attach myself, in my restricted sphere of action, to the said subject, is evidenced in my article headed, "Photometers, Actinometers, Exposure Meters, Exposure Tables, &c.," to which you gave hospitality in your ALMANAC for 1898, p. 705; and as I have since then unremittingly continued in photographic pursuits, by the aid of an exposure meter as my guide and faithful companion, I gladly corroborate Mr. Hett's appreciations, to the extent of asserting my firm belief that very, very numerous as are already the adepts of the black art, legion they would become if they only knew what increase of knowledge, precision, and pleasure they would derive from investing a few shillings in an instrument or two, so as to be able to expose with almost unerring accuracy, in the easiest as well as in the most difficult cases.

To contribute as much and as well as I could to the table-making of comparative figures expressing the speed of plates and their time-exposure, derived from direct actinic light, and following therein Mr. Hett's footsteps, I have constructed the table, as under, on a somewhat different basis to his, having aimed at showing, at a glance, by the actual working of the respective light meters, that all comparative terms indicated are in strict relation to each other, their concordancy being established in the table on only one term of diaphragm and one actinometric term of light for every case tested; but the same correctness and correlation exists for all other factors, and thus renders useless more numerous terms of comparison.

Let us take, for instance, Wynne's F plate speed 39, with *f*-32 diaphragm and 3 seconds actinometer light, and the meter will show—

F 39 - 3  
,, 32 - 2

2 seconds being, in this case, the correct time of exposure.

Compare this now to Watkins' system. To Wynne's *f*-39 speed, the corresponding Watkins' P speed is 24, and we establish the following meter indications—

P 24 first ring.  
D 32 second ring.  
A 3 = E 2 third ring,

or 2 seconds exposure as in Wynne's instrument; any other terms of comparison giving similar results.

Photographers using both instruments will find out that they are constructed on the same principle, the latest-born being, perhaps, more ingenious and more rapid in its working than the first-born, owing to the time of exposure being shown almost magically in one single rotary movement, with the actinometer light illuminated in the centre; but, on the other hand, in the rival meter, the blue glass through which the sensitised paper is seen reaching the standard tint, when exposed to the daylight, is so perfect in its operation, for both whole and quarter tints, that whoever has first worked with one meter and then studied the mechanism of the other will deem it almost necessary to possess the two meters, for the sake of more rapidity in working with one and more security as to the time of exposure with the other. There is, indeed, no doubt, in Watkins' instrument about the accurate concordant decolouration of the sensitised paper, whether this be due to an optical effect

produced by the blue glass or by a different quality of the sensitised paper.

Of course, one maker will consider his instrument the best, and as they are both good, practical, and efficacious, the disadvantages of one being compensated by the advantages of the other, the best the makers can do is to amalgamate their interests, fabricating an instrument combining a simple rotary movement with more correct actinometric exposure. Our two photometric Edisons will surely not repent having cast their lot together, as a perfected instrument would likely considerably increase its sale.

To the following table I have appended several explanatory remarks to make it thoroughly intelligible.

*Comparative table of figures expressing the speed of plates according to Wynne's and Watkins' principles and instruments with actual times of exposure of such figures in relation to f-16 diaphragm and four seconds actinometric light; also comparative table of speed numbers between Wynne's and Hurter & Driffield's systems.*

a	b	c	d	e	f	
Relative Speeds of F and P.	Wynne's F Plate Speeds.	Watkins' Exposure-time with f-16 diaphragm. 4" act. light.	Watkins' P Plate Speeds.	Watkins' Exposure-time with f-16 diaphragm. 4" act. light.	Comparative Plate-speed Numeration between Wynne's F and Hurter & Driffield's.	
1	8	16"	1	16"	8	3"
2	11	8	2	8	11	1½

128	90	¾	128	¾	90	100
160	101	¾	160	¾	101	125
256	128	¾	256	¾	128	200

### Explanatory Remarks.

a. This column represents the relative speeds in Wynne's and Watkins' methods, with figure 1 as starting point, the upright figures constituting a geometrical progression with 2 as common ratio, and the italic figures the multiplying terms by 1 for intermediate exposures.

b. These are Wynne's usual plate-speed symbols, designated by him as *f*, and worked upon in his exposure meter.

c. Here we have the exposure times found by Wynne's exposure meter, for speeds indicated in columns b, with a *f*-16 aperture and four seconds actinometric light.

d. In this column is indicated Watkins' plate-speed symbols, known as *p*, in relation to Wynne's *f* speed symbols.

e. These are the exposure times found by Watkins' exposure meter for *p* speeds indicated in column d, such results being exactly the same as those found by Wynne's meter, and thus testifying to the correctness of this comparative table.

f. This is a table by itself, showing the exact relation between Wynne's and Hurter & Driffield's speed numerations.

Before terminating this article I will still explain for the sake of photographers who are not familiar with direct-light exposure-meters that Wynne's *f* plate-speed numeration signifies a figure indicating the size of the aperture of the diaphragm through which the plate would receive the correct impression of the image of a normal subject with a known actinometric light, whilst in Watkins' numeration the standard for speed, P 1, is such that with *f*-8 diaphragm it requires an equal exposure to the actinometric value of the light. Based on this simple theory, our table has been constructed, and we hope we have made ourselves understood.

GEORGES FARNAU.

### ANOTHER FLASHLIGHT ACCIDENT.

THERE has been another flashlight accident, with fatal result, this time in America, one being killed and several injured. It seems, from the accounts in the daily papers, that the *Columbia*, which is to compete with Sir Thomas Lipton's yacht, the *Shamrock*, for the America Cup, was launched in the evening so as to prevent photographs of her being taken. But a photographer was there, and thought to be equal to the occasion by being provided with a flashlight with which to secure a photograph. Un-

Unfortunately, however, the can of powder exploded, a boy was killed outright, and two severely injured, and others more or less so. Accidents with flashlight powders are continually happening, though some of the powders are said to be perfectly harmless. It would be valuable information to users of flashlights if we were told the composition of those with which the accidents have occurred. All we learn is that "the flashlight powder" exploded. The unfortunate thing in connexion with these compositions is that they seem harmless enough under test conditions, but appear to have a proneness to go off spontaneously when least expected. We have frequently cautioned our readers with regard to the danger of flashlight mixtures, and recommended that the ingredients be kept separate and only mixed with great care at the time of using. This, of course, only applies where the powder is compounded by the user. Several of the powders sold, however, are secret preparations.

### CELLULOID FOR MEASURES.

At a recent meeting of one of the London societies a member alluded to the lack of enterprise in British manufacturers, remarking, according to the report, "that he had at one time tried to induce certain firms working in celluloid to put upon the market graduated measures and other photographic accessories, but was disappointed at the lack of enterprise which he found." A charge of want of enterprise is frequently brought against British manufacturers which is often not well founded. British manufacturers, as a rule, are conscientious and slow to put upon the market articles that they know will not answer the purpose for which they are intended, and that is possibly why they have not adopted the suggestion of celluloid measures. Celluloid, or xylonite, can be produced in close imitation of ivory, but it will not do for ivory scales, rules, or other instruments of precision for which ivory is used, by reason of its shrinkage, owing to the gradual evaporation of one of its constituents, the camphor. The same would, of course, be the case with graduated measures. Moreover, celluloid is softened by heat, and it would therefore be unsuited for measuring hot solutions. Further, it is also soluble in many of the substances that have to be measured—even in photography. For example, it is very soluble in acetone, which is now sometimes used with the developer; so it is in acetic acid, in alcohol, ether, &c. Probably it is the knowledge, by the manufacturers, that celluloid or xylonite measures would be quite unsuitable for general laboratory purposes that has deterred them from putting measures made of that material on the market, and not their lack of business enterprise.

### THE PERMANENCE OF SILVER PRINTS.

A CONTRIBUTOR to the *Photographische Chronik* gives the following particulars of a series of trial prints he has made to ascertain their relative permanence. Six different processes were compared:—

1. Arrowroot paper (prepared by the writer).
2. Albumen paper " " "
3. Matt gelatino-chloride paper, without baryta substratum.
- 4, 5, and 6. Collodio-chloride, gelatino-chloride, chloro-albumen emulsion paper, each with a baryta substratum.

Each print was washed on the day of printing for the same length of time, and the interval between washing and toning was the same in each case. The prints were toned in the same bath and washed before fixing. The strength of the hypo bath was one in twelve, and each print was fixed for the same length of time. They were then washed for four hours each in running water. The prints were surface-dried with pure filter paper, and mounted upon good cardboard (the same in each case) with freshly prepared starch paste. The prints were then exposed for eight weeks in a show-case upon the sunniest part of the external wall of a photographic studio. Result:—

Nos. 1 and 3, upon arrowroot paper and matt gelatino-chloride, without baryta substratum, were unchanged.

No. 2, upon albumen, showed a slight change of tone, but were otherwise good.

Nos. 4, 5, and 6 were in such a condition that any photographer would be sorry to see them if they were prints he had recently sent out.

The writer infers that hyposulphite is not readily removed from a baryta substratum, and that the general opinion that emulsion prints require less washing than others is erroneous. It is self-evident that the hypo saturates the paper, but the presence of a baryta substratum renders its elimination more difficult than in the case of prints without the substratum. There is also the possibility that the substratum forms a

compound with the hypo, which, if retained, acts deleteriously upon the print. The experience of many photographers we know in this country is opposite to this, and others find gelatino-chloride prints more permanent than albumen prints, much as they like the latter process.

### PHOTOGRAPHY IN DOTS.

No doubt there are readers of THE BRITISH JOURNAL OF PHOTOGRAPHY who, if they knew what a simple matter it was, would like to produce a great many of their photographs in dots or what is called grain. The advantages of this kind of work are at least twofold. For many subjects, such as rural scenery and large heads, a grain which simply gives one the idea of a beautiful stipple certainly enhances the softness of the result and takes away that tiring impression of *photograph*. The other advantage is that the photographer will gain much if he then takes a small print, copies it through a grained screen, prints it on transfer paper (to be obtained cheaply from dealers), or a polished zinc plate, and so commences to learn what will, I believe, become an important adjunct to, and inseparable from photography, viz., process work; he may then try his hand at *etching* the zinc. He may also make his own screen, or he may purchase one cheaply—so cheaply, that it would scarcely pay to go to the trouble and dirtiness of making, to say nothing of his having to acquire experience before succeeding. But to return to our subject. There are two ways of obtaining a negative composed of dots. The one is by the use of the ruled screen, the other by the stippled or grained screen. What, then, is the difference between the two? I suppose the ruled screen is used in ninety-nine cases out of a hundred for process work. It is the screen the process workers "swear by," they having got thoroughly imbued with the idea that all process negatives must be made with it.

In artistic work, however, it would be quite useless for producing any pleasant effect such as suggested for large heads or rural scenes. It is, in fact, so unpleasant to the artistic eye, so offensive to artistic taste, that to use it for *effect* would be artistic feeling run mad. We will dismiss it, then, for such purposes, although it would be well to just pause and consider what is the difference between light coming from a lens through small openings such as a ruled screen gives, and coming or passing round an opaque particle or particles as in the grained screen?

The ruled screen produces numberless points of light, which impinge upon the sensitive surface of the plate; the grained screen produces numberless points of shadow by virtue of opaque specks, the light which reaches the sensitive plate in this instance being intersected by grain. Can we, therefore, expect to get in process work results equal in each system? I am now discussing the practicability of using the grained screen for process work, and for the following reason: if a correct copy can be made with a grained screen at 5s., and with less trouble, then why use the ruled screen at all? A similar ruled screen would cost five or six pounds; so far as cost is concerned there is an immense margin of advantage.

Many firms have tried the grained screen and confess to being unable to obtain the necessary results, but I think we must also consider that, just as ruled screens came into use through first one little improvement and another, everybody trying to get a more perfect result than everybody else, so the same amount of evolution should bring about like results with the grain—it would appear that grained screens have had the "cold shoulder" for a long time now. We should also remember that, if the grained screen is old, so is the ruled. I think I am correct in saying that Fox Talbot experimented in this direction with rulings. Single rulings, i.e., rulings in one direction only, were first used, and with these half the exposure was often given with the screen in one position, and finished by reversing the screen so as to get a crossed line; but is it practical to get a small shadow dot or a small high-light dot (one white, the other black) with grain only to work from? At the outset I would point out, first, that over-exposure has a tendency to produce a coarse grain, and that there is no particular distance to be observed in placing a grained screen from the sensitive plate, as the grain must be absolutely in contact with the film. It should be borne in mind that our light is not going to spread by using a certain shaped stop, or any vignetting take place by altering the position of the screen. The grain is going to show in different qualities of fineness according to the selection of light and shadow. Taking the middle tint or tone of our copy, merging to highest lights we get a gradual loss of the standard grain through filling in first the very finest points or particles, then the coarser, until we finally have nothing left but here and there small openings left by the most opaque points, and away down towards the shadows there will be a tendency to produce innumerable fine points, which, clustering together, form substance enough for intensification to lay hold of. This is the selective principle which I have found the light to produce upon a screen I have succeeded in producing by very simple means, and which can be made either for large work or fine. In speaking of fine work I would say that screens can be produced with such a fine grain that the result appears almost like colotype. I think it is a mistake to aim at too uniform a structure in producing grained screens, as it would appear to subdue to a large extent that selective power produced by the lights and shadows of a

picture. There is also a danger of erring on the other side, viz., too great a contrast in structure. Be this as it may, grained screens for giving an artistic effect to a picture are well worth trying. Of course a very fine grain would not be used for artistic work, as it would scarcely be observable. Photographing, or I should perhaps say enlarging, through cloth, or, to be precise, a very finely woven thin silk, commonly called bolting cloth, for the purpose of giving grain, has to my mind always been one of those ideas which tries to make a picture appear what nobody is going to believe it is—an effect on canvas. This, I know, has been largely used; but, if it has no other effect than taking away the crispness or sharpness of a picture, it has succeeded in that. Now, in conclusion, let me remark that with the grained screen we get this same appearance of general effect or roughness without actually having the sharpness of our picture interfered with, and is well worth a trial by any one who wishes to show an effect not obtainable in any other way—so far as simplicity is concerned.

F. G. WILLATT.

### HOLIDAYS AND HAND CAMERAS.

ONE of the first things a man buys when the calendar and hot weather and brilliant sunshine remind him of holidays is a hand camera. His ignorance of the photographic art may be colossal, but his equipment for a holiday is not considered complete without the instrument above mentioned. Is Jones going to Egypt? Every one tells him that he must certainly take with him etc., etc., and bring back records of etc., etc., and thus one more is added to the ragged army of photographic recruits. There is no doubt that many a holiday is utterly spoiled by this inconsiderate meddling of friends and outsiders. Jones, for instance, would be, most probably, far happier without the camera, and, if very sharp and spry, will buy a cheap outfit, drop the same into the Nile at the first convenient opportunity, and let some one else take the photographs.

Now, as a general rule, and admitting the fact that nothing we say is likely to alter the existing state of things as briefly outlined, it is extremely unwise and unsafe, from the technical aspect, to start off on a holiday with a new camera; this is often done, I know, by men who may be termed expert camerists, as well as the immature and embryo amateur. A camera with a changing arrangement of any kind, subtle or otherwise, cannot be too frequently tested and practically worked before taking it into use for serious holiday work. I know of no exception to this rule. It is not a bad plan to let some friendly enthusiast do this for you; there are plenty of amateurs who thrive on failures, nothing seems to cool their ardour, and the merest glimpse of a good negative starts them off afresh every time. Such a man will be delighted to take out the new apparatus and rub off the sharp corners of the inside fixtures, and generally dull the glittering newness of the exterior: there is no greater error than to start off holiday-making with a camera not fully proved, not that the mere testing of the apparatus is a sufficient guarantee, for I distinctly remember one camera which worked admirably in the house and in the office of the manufacturer (where you went to make things warm for him), but which invariably went wrong outside. There are two classes of cameras, those which work satisfactorily only when new, and those which require the discipline of one or more seasons to bring them to their best—and, as a rule, the latter is by far the better article—for various reasons I must not further particularise.

A holiday, as such, to be enjoyable should be free from mental worry and physical discomfort, consequently the camera must be small, light, and portable; in cycling the difficulty is where to hide it; if it can be carried in the hand, gently swaying to the movement of the "bike," we have the best safeguard against vibration and its attendant evils, dust spots, and, worse than all, disarrangement of internal fittings, such as the unrolling of a spool of film. The spring carrier projecting over the handle bar is safe, no doubt, but rather prominent and aggressive. Looking at it all round, I think the most convenient place is on the lamp bracket; most of the smaller hand-cameras, Kodaks, and other magazine film cameras are little heavier, if at all, than the average cycle lamp of to-day, and certainly not so heavy as the old bulky monstrosities of ten years ago, they might easily be made to fit in exactly the same way as a lamp, and with plenty of spring to avoid vibration; the apparatus is in full view, not too much in sight as to be objectionable; in short, we avoid carrying our camera as if it were a Chinese lantern, while for the lamp itself there is room for this on the front fork lower down.

For holiday work, with the cycle especially, all the advantages are mainly with films, rollable and flat; celluloid films may be backed with black gummed paper and other halation preventives, and can be had of varying speeds, but the advantage of using for different subjects backed films, isochromatic films, and films of ordinary and extraordinary rapidity means that dark slides must be carried. It is marvellous, however, what may be done with a length of rollable film of necessarily uniform speed on a holiday tour, embracing a variety of subjects and exposures; provided we are using a lens fitted with diaphragms and a shutter capable of adjustment, the results of exposures may often be extremely uniform, and interiors even, by some dodging of the windows, will be very far from failures. The diaphragms and adjustable shutter require plenty of discretion in their use; if the lens is known to give the requisite sharp picture with a full opening, which may be *f*-10 or *f*-12, it will be well to

take advantage of its capacity and cut down the exposure somewhat. In no other branch of photography is more discrimination required than in hand-camera work, the selection of subject, and the lighting of it, what may be done, and what is best left alone; there are few days when we can say that nothing need be attempted, even with a hand camera, for the lens working at a full aperture will, when we have mastered its powers, do practically all we want; nor are dull, cloudy, sunless days to be despised—sometimes, as I know by painful experience, we may get nothing else; but, nevertheless, not a few picturesque bits are to be seen in our albums, showing that our holiday has not been, from the photographic point, entirely a failure.

J. PIKE.

### NON-ACTINIC APPARATUS FOR DEVELOPMENT.

MR. THEODORE BROWN has devised an apparatus by the aid of which photographic plates or films may be developed between two or more pieces of non-actinic or coloured glass, capable of substantially reducing the power of white light.

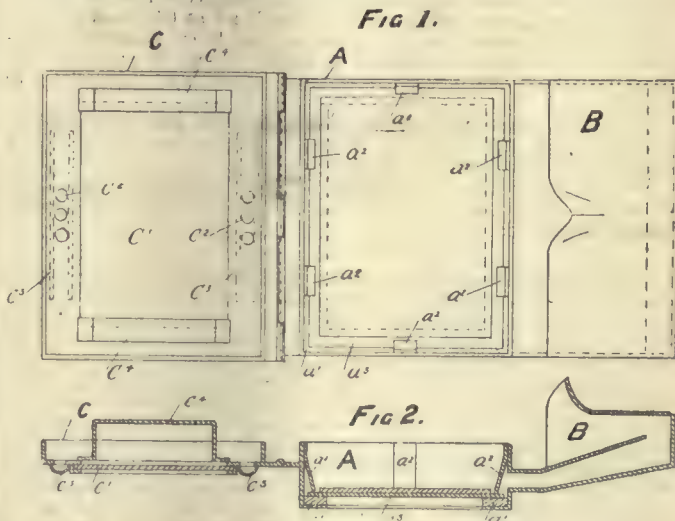

Fig. 1 shows in plan the complete apparatus, and fig. 2 a side section of same. The apparatus comprises a box, A, with a hinged lid, C, having attached to its side a kind of ante-chamber, B. The bottom of the box is fitted with a piece of coloured or non-actinic glass,  $\Lambda^2$ , covering a suitable size opening made in the bottom and resting upon a rubber moulding,  $\Lambda^1$ , fixed to the bottom of the box.

The said coloured or non-actinic glass,  $\Lambda^2$ , is kept in position by being tightly pressed against the said rubber moulding,  $\Lambda^1$ , by a suitable number of metal tongues or springs,  $\Lambda^3$ , attached to the side of the box, A, and thus producing watertight joints.

The glass in the bottom of the box, A, is so fitted, as described in order that it may easily be replaced with a fresh piece, should it get broken or damaged in any way.

The lid of the box, C, is also fitted with a piece of coloured or non-actinic glass,  $C^1$ , but is permanently fixed as shown in fig. 2.

The cover, C, is perforated at two sides, at  $C^2$ , which perforations are

arched over at  $C^2$  in such a manner as to exclude direct rays of white light from the box when it is closed.

Two projecting parts,  $C^4$ , are fixed to the under side of the cover, C, so that when the box is closed the said two parts,  $C^4$ , extend toward the bottom of the box far enough to prevent the photographic plates or films from loosely falling about when the box is closed.

The ante-chamber, B, is so constructed that direct rays of white light may not enter the said box, A, but at the same time will permit of the entrance of liquids.

The photographic plates or films intended for development are placed in the box under cover from daylight, and the lid closed.

The apparatus containing the photographic plates or films is then taken out into broad day or artificial light.

The liquids employed for the development is then poured into the ante-chamber, B, and allowed to run down into the box, A, containing the photographic plates or films, by laying the whole apparatus flat on a table. When the operator desires to examine the progress of the development, the plate or film is examined by allowing the liquid to drain off into the ante-chamber, by holding the apparatus up before a strong light. When the various stages of development have been performed in this manner, the cover is opened and the photographic plate or film is taken out and dried in the usual manner.

## THE AUTUMN EXHIBITIONS.

We append particulars of four important photographic Exhibitions to be held next autumn.

## ROYAL PHOTOGRAPHIC SOCIETY.

The Exhibition will remain open daily (Sundays excepted) from Monday, September 25, until Saturday, November 11, from 10 a.m. till 5 p.m. It will also be open on Monday, Wednesday, and Saturday evenings, from 7 to 10 p.m., when lantern slides will be shown.

Medals will be placed at the disposal of the Judges. Exhibitors may state whether they wish their exhibits to be placed in the Pictorial or the Technical and Scientific Section. Exhibits not marked P. or T. will be dealt with in such section as the Selecting Committee may consider appropriate, but exhibits may be excluded from the Technical and Scientific Division unless the points of special interest are distinctly stated. The Exhibition will be conducted according to the rules adopted at the Conference of Judges.

The Judges are:—Pictorial Section: Mr. Harold Baker, Colonel J. Gale, Mr. A. Horsley Hinton, Mr. B. W. Leader, R.A., Mr. W. L. Wyllie, A.R.A. Technical and Scientific Section: Captain W. de W. Abney, C.B., F.R.S., Mr. T. Bolas, F.I.C., F.C.S., Mr. Chapman Jones, F.I.C., F.C.S.

The following comprises the Selecting and Hanging Committee:—Pictorial Section: Mr. R. Child Bayley, Mr. J. A. Hodges, Mr. H. Vivian Hyde, Mr. A. Mackie, Mr. J. C. S. Mummery, Mr. J. B. B. Wellington. Technical and Scientific Section: Captain W. de W. Abney, C.B., F.R.S., Mr. T. Bolas, F.I.C., F.C.S., Mr. F. A. Bridge, Mr. Chapman Jones, F.I.C., F.C.S., Mr. J. J. Vezey, Mr. E. J. Wall.

Each exhibitor must fill up the entry form supplied by the Society, and send it by post to the Secretary, Royal Photographic Society, 66, Russell-square, London, W.C., on or before Tuesday September 5, or deliver it with the exhibit (not packed) by hand at that address on or before Wednesday, September 6, at 9 p.m.

Exhibits sent by carrier must be *carriage paid*, and addressed to the Secretary, Royal Photographic Society, 66, Russell-square, W.C., and must arrive on or before Tuesday, September 5. No charges whatsoever will be paid by the Society on exhibits sent unpaid or upon which the carriers require payment, and all exhibits so tendered will be refused.

Exhibits not packed may be delivered by hand at 66, Russell-square, W.C., at any time between 10 a.m. and 4 p.m. before Wednesday, September 6. On that day they will be received from 10 a.m. to 9 p.m., after which time and date no exhibit can, under any circumstances, be received.

Very large frames and bulky or fragile apparatus may be delivered at the Gallery, 5a, Pall Mall East, if special arrangement, *beforehand*, is made with the Secretary.

Blank entry forms and any further information respecting the Exhibition can be obtained from the Secretary of the Society, 66, Russell-square, London, W.C.

## THE PHOTOGRAPHIC SALON.

The Seventh Annual Exhibition will be held at the Dudley Gallery, Egyptian Hall, Piccadilly, from September 22 to November 4, 1899. The receiving day is Monday, September 11, from 10 a.m. to 6 p.m., on which day all pictures for exhibition must be delivered at the Gallery, either personally or through an agent.

Careful consideration will be given to all pictures entered for exhibition, and a selection of works of pictorial merit made by the Committee. Pictures which have already been publicly exhibited in London will not be accepted. Pictures sent for exhibition to any other exhibition open in London at the same period are liable also to be disqualified. No awards are offered, and no charge is made to exhibitors. Exhibitors will be entitled to a season ticket. Arrangements will be made for the sale of pictures, if desired, and a commission of fifteen per cent. will be charged on sales effected.

Pictures will be received at the Dudley Gallery *only*, on Monday, September 11, from 10 a.m. to 6 p.m.

Mr. William Whiteley, of Westbourne Grove, will undertake to receive, deliver, and return exhibits.

Terms and all other particulars may be obtained of the Hon. Secretary, Photographic Salon, Dudley Gallery, Piccadilly, W.

## THE PHILADELPHIA PHOTOGRAPHIC SALON.

The Pennsylvania Academy of the Fine Arts announce that, under joint management with the Photographic Society of Philadelphia, the Philadelphia Photographic Salon for 1899 (second year) will be held in the Galleries of the Academy, Broad-street, above Arch, from October 22 to November 19, 1899.

Pictures which have already been shown in Philadelphia at any exhibition open to the general public will be liable to exclusion.

No awards are offered, and no charge will be made to exhibitors. Each exhibitor will be furnished with a catalogue, which will be the official notification of acceptance.

No exhibitor may submit more than ten pictures, each of which *must* be framed separately.

Arrangements will be made for the sale of pictures if desired, subject to a commission of fifteen per cent.

All communications and all pictures submitted for exhibition must be addressed to the Pennsylvania Academy of the Fine Arts, Broad-street, above Arch, Philadelphia, Penna., U.S.A. All pictures must be forwarded at owner's risk, *carriage prepaid*, and delivered at the Academy not later than 5 p.m., Monday, October 2, 1899.

Mr. A. Horsley Hinton, 1 Creed-lane, Ludgate Hill, London, E.C., has consented to act as general foreign representative. Circulars, entry forms, labels, &c., also any special information desired will be furnished by him on application.

The following shipping agents have also been appointed:—Mr. William Whiteley (Mr. Wiggins, manager, Shipping Department), 115, Queen's-road, W., London, England; and Messrs. Guinchard & Fourniret, 76, Rue Blanche, Paris, France.

The following is the jury of selection:—Mr. F. Holland Day, Boston; Mrs. Gertrude Kasebier, New York; Mr. Clarence H. White, Newark, Ohio; Miss Frances B. Johnston, Washington, D.C.; and Mr. Henry Troth, Philadelphia.

## THE CROYDON CAMERA CLUB.

The Croydon Camera Club will hold an Exhibition at the Art Gallery, Park-lane, Croydon, in the week, October 18 to 24 next. There will be open classes for prints and slides, and a special class for amateurs resident in the borough of Croydon. The prospectus will shortly be issued.

## THREE-COLOUR WORK AND THE KURTZ PATENT IN THE UNITED STATES.

Mr. A. C. AUSTIN has the following observations on this subject in an American contemporary:—

Banning and Banning, of Chicago, Ill., specialists in patent law, have sent the following letter to a number of photo-engravers throughout the country during the past few weeks, causing in some cases a little trepidation, and in nearly all cases considerable discussion concerning the matter at interest, the Kurtz patent.

"Messrs. GENTLEMEN,—As attorneys for the New York Colortype Company, we hereby notify you that in its photo-mechanical printing your company is infringing the William Kurtz patent, No. 498,396, dated May 30, 1893, owned by our client; and we hereby request you and your company to immediately desist from further infringement thereof. Unless you are willing to do this, we will have to begin suit for an injunction and damages. Requesting an immediate answer, Yours very respectfully, BANNING & BANNING."

Chicago, April 13, 1899.

In reading the above one's attention is impressed with the singular fact that a New York corporation is represented by Chicago attorneys, and the natural inquiry is, Why? A little quiet investigation develops an assertion that the New York Colortype Company, a recent corporation formed upon the ashes of the old Colortype Company, have secured all the right, title and interest in the Kurtz patents with the avowed purpose of prosecuting all infringers, and with the expectation of making more by the granting of licences than they can by the making of the colour plates, provided, of course, that they can maintain their patent rights.

Rumour has it that there is a strong combination between the New York corporation and the Chicago Colortype Company, which would account for the western attorneys, and, although this has been denied by one of the officials of the New York company, it seems very reasonable. The New York official asserts that the Chicago firm is working under licence, which is the only interest they have.

The one and the other assertion are immaterial to the majority of us. We have only to consider as to whether it is safe for us to defy the threatened injunctions, or whether we should be prudent and endeavour to negotiate for a licence or go out of business. With a view of determining the best course of action, let us study the facts in the case. In the letters patent, Mr. Kurtz recites the reasons for the "moiré effect," or "confusion of lines," that result from the printing of one half-tone over another, and claims that the only way such results can be avoided is by the use of "a screen with parallel lines running in one direction only, the lines of one negative running in a different direction from the lines of the other negative," &c. On the face of it, we who have long since learned to regard the single-line screen as obsolete and to recognise the advantages of a cross-line screen in connection with an elliptical or slit diaphragm, laugh at Mr. Kurtz' claims, and think there can be no possible cause for action from the fact that we do not nor would not use a single-line screen if we could do so without any interference. Possibly, though, we are laughing a little too soon, and for us to maintain a right to use a cross-line screen is but playing into the enemy's hands. Let us ask ourselves, What is a cross-line screen? and what can we say but that it is a screen composed of two single-line screens cemented together with the lines running in opposite directions? Here indeed is a problem for legal solution. Do two single-line screens cemented together as a homogeneous whole still retain their single line characteristics, or does the fact of their being joined together endow them with properties so totally different as to render them a distinctly different thing? Are there any properties within the possibilities of a cross-line screen that cannot be demonstrated with a single-line screen?

If these questions can be answered in the affirmative, it would seem as

though Messrs. Banning & Banning had a difficult task before them. There are a great many things to be taken into consideration. Whether we can or cannot do this or do that is a question for the courts to decide, and meanwhile they who act in defiance of the Messrs. Banning's warning lay themselves liable to damages if in the end the decision should be favourable to the maintenance of the Kurtz patent.

Probably a goodly number who have found three-colour work anything but profitable will grasp the opportunity as an excuse for quitting the field, because in this way they can gracefully desist without having to acknowledge a failure. Many cannot fight because of financial reasons and many will not fight from prudence. Therefore, be it "bluff" or be it belief in vested rights, the Kurtz people seem to have the better end.

What shall we do about it? Do we really need three-colour work to help along a business that all acknowledge is not the best in the world? Is it best to put it aside that it may become a monopoly? I believe we do need it, because there is a margin of profit in the work if properly conducted, and certainly we need all the profit that is possible in the photo-engraving line.

I do not think Mr. Kurtz' successors deserve to monopolise the whole thing, for neither they nor Mr. Kurtz, for that matter, have made the process what it is to-day. Many bright minds have given serious study and many dollars to its perfection, and, if it had not been for these bright minds and many dollars, the process could not have been a commercial success, for Mr. Kurtz and his original company made a sad failure themselves.

Looking at it in this light, it would seem best to fight the issue. Make combined effort. If each and all contribute, the individual tax would be but nominal, and it is only by combination that we can ever expect to for ever set at rest the uncertainty.

#### YORKSHIRE PHOTOGRAPHIC UNION: FIRST ANNUAL EXCURSION.

THE Yorkshire Photographic Union is yet in its infancy, but it must be admitted the infant is an exceedingly healthy and energetic one. Many difficulties attending the final establishment of the Union have had to be overcome, relieved not one whit by the unkind croakings of adverse critics. However, to a greater or less extent, this has been abortive, and the Union is now recognised as one of the institutions of the county. To the energy of the President (Mr. Percy Lund), the Hon. Secretary (Mr. Ezra Clough), and the committee generally, the bulk of this success must be ascribed.

Saturday, the 17th inst., must be designated as a virtual "field day" in connexion with the Union, inasmuch as that was the occasion on which the first annual excursion was held. The destination was Selby, the weather delightfully fine, the party numerous and representative, and the whole affair a complete success.

Leeds was the centre at which the members from various parts assembled, and they were there taken in hand by Mr. J. Groisdale Coultas, the courteous Secretary of the Leeds Photographic Society. This refers to the first contingent, which were "dispatched" at 9.25 a.m. The later detachment followed at 1.22 p.m., and on arriving at Selby were met by those who had preceded them, and together boarded a special train, the destination of which was Cawood.

It was now ascertained that the party was upwards of seventy strong, and included members from Bradford, Leeds, Hull, Halifax, Pudsey, Yeadon, and Brighouse.

The run to Cawood was only a brief one, and the conversation on the way was, of course, one which required but little time for "development" under such favourable conditions. The detrainment was apparently regarded with much interest by the natives, who seemed to view the varied and vast array of photographic armament with commendable awe and wonderment.

There was no waste of time. Operations were commenced at once, and "shots" were flying about in all directions. No set plan of campaign had been arranged, for every operator was a power unto himself, and preferred to be his own general, with the view, no doubt, of out-generalising every other artistic operator. Hand and stand machines were quickly at work, mostly directed at a pretty bit of rural scenery with some cottages in the distance, and a picturesque and sloping bank touching a meandering stream further afield. One enthusiast in the party caught what should prove an interesting plate of a cottager sinking the bucket in the well. From an artistic point of view, Cawood Castle came in for the major share of attention, and the party was shown the ancient banqueting-hall, now used as a shippen, and the court-house, where court leets are still periodically held. It is said that Cardinal Wolsey was imprisoned here for a brief period, and the old place is now turned into a model farmstead.

Afterwards the party drifted on to the river, where several views were secured, with boats and barges in the foreground. Another detachment, however, oscillated in a slightly contrary direction, and expressed hearty approval of the home-brewed provided by mine host.

One of the prettiest pictures obtained during the day was that of the confluence of the Wharfe with the Ouse, and doubtless we shall see this in many a screen during the winter months.

It was delicious dawdling on the river banks, and enjoying the exercise

of our scientific skill, in such glorious atmosphere and sunshine; but everything must have an end, and marching orders were given for the station.

Selby was reached about six o'clock, and an excellent tea was provided at the Londesborough Arms Hotel.

After tea it was suggested that a little oratory would be an agreeable change, and, with his usual readiness, Mr. Percy Lund at once obliged. He remarked that he was not going to inflict a long speech upon them on this the first occasion of their meeting together in connexion with the Yorkshire Photographic Union, but the gathering, being the first of its kind, seemed to call for a few introductory remarks from himself. Proceeding, he said that, when a few months ago each of the Yorkshire societies had decided to venture upon the experiment of union with fellow societies, probably to the majority who were acting as delegates for their societies the union did not for a time appear to have any real or tangible existence, nor did its proposals seem within measurable distance of realisation; but, when the representatives of the newly constituted organization had met together in solemn conclave and got through the preliminary stages of constitution and outlined a plan of working, it was a source of congratulation for them to find that the seeds they had sown in faith had given rise to a vigorous plant, and that plant had put forth a flower in many ways.

In the first place they had had a most successful annual excursion that day, and the glorious sun, who played no secondary part in photographic work, had given them his warmest support. He trusted and they hoped that the flower would in due time bring forth abundant and good fruit, and that the Yorkshire Photographic Union would increase and prosper, and bring about innumerable useful results as a reward for the labour and energy that had been bestowed upon it. The lecture scheme had already become an accomplished fact, and the list of twenty-five gentlemen able and willing to speak on numerous subjects was in the hands of individual secretaries, so that when the lecturing scheme went round the movement would be felt throughout the country. Apart from the proposals already on the programme such as interchange of slides, &c., there were very important matters entitled to consideration.

He thought the Union should possess a first-class collection of pictorial photographs for the purpose of lending to societies and to the Geological Photographic Committee of the British Association, and to assist in bringing about the adoption of the metric system would be most beneficial, whereas at present such a confusion of systems existed. Those were only a few of many points to which attention should be devoted. Good service would have been performed by the Union if it did no more than bind together a number of individual societies scattered throughout the country, and foster an intelligent study and love of photography. For, whether in commerce, science, art, or architecture, the camera as a recorder was becoming almost as indispensable as the pen, and he believed the time would come when our children's children would receive at the same time and with their pencils and drawing boards a portable camera and a roll of sensitive film. If the Union did none of these things but encouraged photography as a hobby, it had established a right to exist, for, plunged as we were in the deep sea of commercialism in working and worrying for precious metals, photography might be likened to the loadstone which held us fast to nature and to that divine spirit which was behind all the truest and best things in the world.

Mr. Godfrey Bingley (Leeds Photographic Society) said they could not separate on that occasion without passing the warmest thanks to the Rev. A. J. Tweedale, who had kindly given them permission to photograph in the Abbey Church, and also to Mr. Wormald, of Cawood, for having generously allowed them to go unrestricted in any part of the grounds, and to Mr. Prosser for permission to roam over the bacon factory, and last, but not least, to Mr. W. N. Cheerman, a local photographer, who knew all about Selby and the Abbey. He proposed that their warmest thanks be given to those gentlemen he had named for the great kindness and help in that day's proceedings.

Dr. Hollingworth (Hull) warmly seconded the vote of thanks, and the members heartily accorded it.

Mr. Clough said he might mention that there were seven societies represented there that day, and in regard to the lecturer's list he would advise the secretaries, although only two lectures had been promised, to get as many as ever they could. He wished to draw the attention of secretaries to the fact that he would like a notification or some rough idea as to the number of lantern slides each society was prepared to send in to the judges, and as to the excursions an intimation of the most suitable day or any other suggestions.

The party were afterwards grouped and photographed in the grounds of the Londesborough Hotel, and then broke up, some leaving by the 7.10 and others remaining until 9.30. It was the universal opinion expressed that a more delightful outing and gathering could not have been experienced.

#### THE IMPERIAL DRY-PLATE WORKS.

It is seven years or more since we visited the works of the Imperial Dry Plate Company at Cricklewood. It was in the early part of 1892, and the first few gross of plates lay really packed for sending out. Indeed, we believe that the very first dozen half-plates which left the building were used by ourselves, and exceedingly fine plates we found them.

Since the year 1892 matters have progressed very rapidly at Crickle-

wood, which from nothing but a mere hamlet has developed into a very large and prosperous suburb indeed. A visit to the Imperial Company's works one afternoon last week enabled us to perceive that great additions have been made to those buildings since we first saw them. The frontage of the ground occupied by the works extends to more than 170 feet, with a depth of about equal dimension. The original dry-plate building has been added to on three sides, and there are separate factories for P.O.P. and bromide papers. Roughly speaking, the area of the Imperial Company's buildings has been multiplied some four or five times since our visit.

The activity of the engines and dynamos and the sight of a vast pile of plates ready packed for sending away were sure indications that the very greatest activity prevails at the Imperial Works. The success of the Company's sensitive preparations can hardly be wondered at, for one is constantly hearing them spoken of as exceedingly good and regular in quality. All the building work, electric lighting, and fitting up of the dry-plate, P.O.P. and bromide factories was carried out under the personal supervision of the managing director, Dr. J. J. Acworth, whose success has been thoroughly well deserved. Indeed it is when we contemplate the growth and expansion of the Imperial and other dry-plate firms in recent years that we become more than ever convinced of the firm and permanent hold which photography has obtained upon all classes of the community. Ever since our association with photography, now twenty years or more, we have been listening to occasional apprehensions lest photography should die out. And yet photographic manufactures were never in so flourishing a state as in the last few years.

#### A PHOTOGRAPHIC GARDEN PARTY.

It was a happy idea of our old friend, Mr. A. L. Henderson, to invite the members of the London and Provincial Photographic Association, a body in which he takes the keenest interest, and of which indeed he was the founder some seventeen years or so ago, to visit him at his house, Brimsdown, Middlesex, on Saturday afternoon last. The weather was beautifully fine, and the trees and fields, in their early summer tints of green, looked at their best and freshest.

Mr. Henderson's house, which is surrounded by some fourteen acres of land, broken up into a pleasant variety of smooth lawn, hayfields, flower and kitchen gardens, and plentifully sprinkled with trees and bushes, is of some slight historical photographic interest, as it was formerly occupied by the once well-known photographer J. E. Mayall, thrice Mayor of Brighton. We need hardly say that it has many objects of photographic value and interest, which were eagerly examined by Mr. Henderson's visitors in the course of the afternoon.

About thirty gentlemen responded to Mr. Henderson's invitation, amongst them being Messrs. A. Cowan, T. E. Freshwater, A. Mackie, Thomas Bedding, P. Everitt, S. H. Fry, — Fry, junior, A. W. W. Bartlett, J. E. Hodd, R. A. Hodd, R. P. Drage, H. E. Davis, J. S. Teape, A. J. Brown, J. A. Sinclair, S. C. Mote, and others. It was quite an old-fashioned "L. and P." gathering, but without the characteristic argumentativeness which usually prevails at formal meetings of the Association. Mrs. Henderson and Mr. and Mrs. Gray kindly assisted the host in receiving the guests, and refreshments were served on the lawn, where tea and supper were partaken of. Most of the party were provided with cameras, and many opportunities were availed of in the pretty grounds for taking groups and snap-shots. Visits were also made to one or two places of interest in the neighbourhood. The afternoon seemed all too short in the pleasant surroundings, amongst which Mr. Henderson diversifies his photographic work with pursuits of an agricultural and pastoral nature. At the end of a charming day Mr. and Mrs. Henderson were cordially thanked for their hospitality, and the members of the "L. and P." returned to town highly delighted with their outing.

## Our Editorial Table.

#### TUBOL.

We have received from the old-established firm of Ed. Liesegang, Düsseldorf, a sample of developer sent out by them under this name. The method of packing is unique, and will commend itself to the tourist and traveller for safety and convenience. The ingredients forming the developer are mixed in a stiff greyish paste, and enclosed in collapsible metal tubes, the same as artists' colours. For use the mixture must be diluted by addition of 50 parts of water for instantaneous exposures, and 70 parts for ordinary landscape work. As the paste retains its filiform shape when squeezed from the tube, it is easy to measure the quantity by length. About 2½ inches will be found sufficient for 2 ounces of developer, and a few minims of a ten per cent. solution of bromide of potassium should be added. The diluted developer will keep a considerable length of time. In use we have found it very efficient and free from stain, bringing up the image steadily with ample detail. We put it to a severe test by using some orthochromatic plates, which we know are several years old, and were gratified to find the negatives full of detail and free from fog.

The Bay State Photo Company, of 124, Hospital-street, Nantwich, send us a sample bottle of their combined toning and fixing bath, together with some prints toned in a similar solution some years ago, and which, though exposed to light, appear to have stood well. From the same source we have also received a sample bottle of a new one-solution developer—Developall. This is claimed not to stain, and to work well with plates and papers. The Company intend sending out 1000 samples to those applying for them.

Mr. C. C. VEVERS, of 54, Grand-arcade, Briggate, Leeds, sends us a sample of his new "Kepvel" preservative parchment envelopes. When repacking plates on tour, the amateur will find them very useful, as he can then carry his plates without fear of scratching or rubbing the film. For storing negatives they also have some advantages over the ordinary negative bags, as they are smooth, tough, and translucent, allowing the negative to be seen and recognised without the trouble of removing it from the envelope.

MESSRS. E. MARLBOROUGH & Co., of 51, Old Bailey, E.C., are issuing a decidedly useful little book on *Italian Self-taught*, by C. A. Thimmes, F.R.G.S. The correct pronunciation of this beautiful language is given, and amongst others there is a photographic vocabulary, whose only fault is its brevity. In paper covers the book sells at 1s., or in cloth, 1s. 6d.

Mr. PERCY LINDLEY, of 30, Fleet-street, E.C., sends us the first number of the London, Brighton, and South Coast Railway Company's *South Coast Quarterly*. It is said to be the first publication of its kind issued in England. Touring and topography supply its *raison-d'être*, and, besides many sketches and phototypes of scenes in the country, French and English, that is served by the Brighton Company, there are many interesting descriptive notes. The *South Coast Quarterly* will, doubtless, appeal to many photographers.

From the Scovill & Adams Company, of New York, we have received a handy little pocket-book on *The Half-tone Process*. The information given on the use of screens and diaphragms is very full and comprehensive.

*TRAITE Pratique de Photographie Stéréoscopique* is the title of a work on binocular photography by that prolific writer Mons. L. Mathet. It is published by Charles Mendel, Paris, and is in French. The theory and practice of the subject are fully dealt with.

PART II. of a *Reference Book of Practical Photography*, by Mr. F. Dundas Todd, Editor of the *Photo Beacon*, Chicago, has reached us. The matter appears to have been well selected and the photographer will find the little book reliable and informative.

#### CATALOGUES RECEIVED.

E. & T. Underwood, 130-132, Granville-street, Birmingham.

In sending us a copy of their latest catalogue, Messrs. Underwood point out that among the new goods now listed are the *Pacts*, a low-priced set, of good workmanship and finish, and having a rapid rectilinear lens, with iris diaphragm.

They rightly observe that there are many people who want to do a little photography without going deeply into it, and with them a rapid rectilinear lens is of greater consideration than many of the usual camera movements.

The *Field*, *Club*, and *Umbra* cameras are also listed, and the *Umbra* is now made for stereoscopic work, the half-plate being also available in the same instrument.

The *Salon* and *Royal* are two new high-class cameras, having a set of supplementary lenses for use with the rapid rectilinear attached to the *Umbra*.

Among the minor improvements in Messrs. Underwood's hand cameras that called the *Sphinx* is now fitted with patent handle sheaths, allowing two or more sorts of plates being carried and either used at will.

The catalogue is beautifully printed and contains reproductions of many fine photographs taken by Mr. Underwood and other gentlemen, and, as there are many practical hints on the uses of photographic apparatus and lenses, it should prove of very great service to amateur photographers and others.

#### PHOTOGRAPHISCHE OBJECTIVE UND OPTISCH-PHOTOGRAPHISCHE HILFSAPPARATE. 1899.

Carl Zeiss Optische Werksstätte, Jena.

We have just received the latest edition of the catalogue of photographic lenses and optical accessories manufactured by Messrs. Zeiss, and the excellence of its arrangement and the completeness of its detail leave nothing to be desired. Compared with the previous edition we notice three new features of special interest. These are Dr. Rudolph's Planar Lens

(Series Ia), which is sent out in foci ranging from 2 to 61 cm.; a new set of diaphragms with multipartite apertures for process work; and an improved form of iris shutter with adjustable speed-regulator. The present catalogue should be of great value to the users of Messrs. Zeiss' justly celebrated lenses.

J. Roeder, Frankfurt am-Main, Bockenheim.

This catalogue is printed in two languages, French and German, and gives illustrated particulars and prices of photographic apparatus of Continental manufacture.

## News and Notes.

PHOTOGRAPHIC CLUB.—June 28 1899, at eight o'clock. "Notes on Some Novel Photo-mechanical Printing Machinery," by Mr. H. Snowden Ward.

MESSRS. MATTHEWS & CO., gold and silver sweep dealers, inform us that they now have premises in working order for bullion and assay offices, at 42, Great Queen-street, Lincoln's Inn, London, W.C.

THE AUSTIN-EDWARDS MONTHLY FILM NEGATIVE COMPETITION.—The prize camera for the current month has been awarded to Miss Ivy Weston, 23, Sandgate-road, Folkestone, for her negative, *Portrait of Child*.

MESSRS. ROTHWELL & ROTHWELL, commercial photographers, trade photographic printers, and enlargers, publishers of lantern and stereoscopic slides, &c., have removed to 18, Norfolk-street (opposite G.P.O.), Manchester.

THE Photochromoscope Syndicate, Limited, inform us that, in consequence of the expiration of their lease of 121 and 123, Shaftesbury-avenue, W.C., from June 10, 1899, their business will be carried on temporarily at the works, 28, The Pavement, Clapham Common, S.W.

MESSRS. RAINES & CO., photographic enlargers, &c., of St. Mary's-road, Ealing, W., inform us that, notwithstanding the recent destruction by fire of a portion of their premises, they are able to continue their work as usual, and that all orders are being executed without delay.

KODAK, LIMITED.—The Directors of Kodak, Limited, have declared an interim dividend on the Company's preference issue for the quarter ending June 30, 1899, at the rate of six per cent. per annum, and on the ordinary shares at the rate of ten per cent. per annum for the same period, which dividends will be payable on or after the 1st prox.

THE cycling section of the South London Photographic Society will hold their second annual midnight ride to Brighton on the 24th-25th inst., starting from Streatham Corner at 12.30 a.m. The headquarters are at 53, London-road, Brighton. Members and their friends are desired to communicate with the cycling captain, Mr. Howard Ealer, 4, Queen's-road, Peckham.

THE Electrolytic Salts Company have received a report on the "process" of extracting gold from sea water. The professor whom the directors employed reports that the process was fraudulent. The directors are said to have recovered a considerable sum from the originator of the swindle, which, together with the sale of the machinery, &c., has realised enough to pay 20 per cent. dividend to the stockholders.

MR. GEORGE P. GIBSON, chemist and photographic dealer, of West Church-street, Buckie, N.B., writes: "I noticed in your issue of July 1, 1898, a list of persons having dark rooms for use of the public, tourists, &c., and who are also dealers. You might insert my name. Buckie is a good place for the amateur photographer visitor. It is situated on the Moray Firth, with good bathing, golf, &c. A good many visitors come here from all parts."

MR. RICHARD KEARTON is in Scotland gathering material for another natural history volume. His method, of course, is to study nature on the spot alike with camera and pen. He has been able, in this way, to collect into his books a singularly interesting series of pictures. To the general reader, who can always understand a picture, these have, no doubt, been a great attraction. Mr. Kearton's new volume will, in some degree, be a sequel to a previous one dealing with British birds' nests. It will be ready in the autumn.

THE Paget Prize Plate Company had their annual outing on Saturday last, a most enjoyable day being spent at Bournemouth, which was reached by special train from Watford at 9.15 in the morning. As this necessitated a somewhat early start, breakfast was served to the whole of the staff on their arrival, and, thus fortified, they betook themselves to enjoy the many and varied opportunities for diversion which Bournemouth affords. The return journey was commenced at 7 p.m. from Bournemouth, and, after a pleasant run, Watford was reached at 11.30 p.m.

THE Monroe Camera Company, of 2, Old-street, Goswell-road, E.C., write: "We regret to say that, in our catalogue, as well as in our advertisements, Lloyd's Rotary Trimmer has been listed wrongly, and we should be obliged if you would change it as below, and give due publicity in your columns to it, as we do not want to run the risk of being credited with the intention of defrauding the public:—No. 0 Lloyd's Trimmer at 8s. 6d., cuts nothing larger than 5½ inches square; No. 1, at 12s., 7½ inches square; No. 2, at 15s., 8½ inches square; No. 3, at 18s. 6d., 10½ inches square.

THE names of the prize-winners in the Warwick Monthly Competition for June are: 1st prize, 10L, Mr. R. S. Webster, 60, Princes-street, Edinburgh, *A Canny Scot*; 2nd prize, 5L, Miss Ivy Weston, 23, Sandgate-road, Folkestone, *Three Child Studies*; twenty prizes of 1L each, Misses Janet Reid and Winnie Halett, Messrs. T. F. Brogden, T. U. Simonson, C. J. Allin, E. A. Price, C. Metcalfe, R. A. B. Bennett, T. H. Baker, W. Baldwin, Cecil Gethen, H. E. Watkin, Alfred Bainbridge, G. Adams, J. Williams, J. Terras, A. B. Carr, J. W. Wharton, Q. O. Grogan, and H. M. Hallsworth.

ALLEGED FRAUDS.—At the Gainsborough Police Court on Friday, Robert Audens and Fredrick Hart, of Grimsby, described as photographers, were charged with larceny by trickery. From the evidence of Robert Morris, a farmer, of Scotton, it appeared that, on April 25 last, the prisoners persuaded him to have a photograph taken of his house, and a family group. He paid them 14s., and they promised to send on the photographs in nine or ten days, but he heard nothing further from them, and, not having their address, he could not communicate with them. When prisoners were arrested, they had in their possession negatives and a number of rough prints of the photographs, and they said that, owing to the weather, they had been unable to complete the photographs. Superintendent Eagley stated that there were likely to be further charges preferred against the prisoners, and they were remanded in custody.

X RAYS ON THE BRAIN.—A paper was recently read by Mr. W. B. Delamatre before the Illinois Homoeopathic Association of Chicago on the use of X rays in the diagnosis of injury to the skull and in brain disorders. He found it necessary to take photographs, as they enable the location and extent of the fracture or other injury to be discovered with much greater exactness than a mere observation with the vacuum tube. In some cases of insanity a diagnosis by means of the X rays had been found of assistance either in showing abnormal conditions, rendering operation useless, or indications that might render it hopeful. Circumscribing thickness of the skull was readily indicated by means of the rays, and tumours and abscesses had also been detected by the same agency. In the case of blood clots, as they do not differ greatly from the surrounding tissue, they could not be identified, but degeneration of the brain tissue, which generally alters the density of the brain, can, according to Mr. Delamatre, be diagnosed, although we should have thought that such diagnosis would only be possible in cases in which the disorder had reached an advanced stage.

## Patent News.

THE following applications for Patents were made between June 5 and June 10, 1899:—

SHUTTERS.—No. 11,600. "Improvements in Photographic Shutters." J. E. THORNTON.

ANIMATED PHOTOGRAPHY.—No. 11,997. "Improvements in Animated Photography." R. W. PAUL.

FOLDING CAMERA AND SHEATHS.—No. 12,058. "Improved Folding Photographic Camera and Photographic Sheaths or Carriers." A. L. ADAMS.

FILMS.—No. 12,152. "Improvements in Photographic Films." G. MACAIRE.

CAMERAS.—No. 12,180. "Improvements in and relating to Photographic Cameras." Communicated by J. G. Siegrist. Complete specification. J. C. FELL.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
24.....	Ashton-under-Lyne.....	Excursion: Llangollen. Leader, Chas. Lord.
27.....	Hackney.....	Open Night
27.....	Royal Photographic Society ..	Slide at 66, Russell-square, W.

28.....	Photographic Club.....	Notes on some Novel Photo-mechanical Printing Machinery H. Snowden Ward.
29.....	London and Provincial.....	Annual General Meeting.
29.....	Oldham.....	Demonstration. T. Widdop.
July.		
1.....	Borough Polytechnic.....	Excursion: Sewardstone. Leader, A. Bedding.
1.....	Darwen.....	Excursion: Jumbles, Turton.

### ROYAL PHOTOGRAPHIC SOCIETY.

JUNE 20.—Technical Meeting.—The Right Hon. the Earl of Crawford, K.T., F.R.S. (President) in the chair.

#### RETOUCHING.

MR. REDMOND BARRETT read a paper on "Retouching," in which, after a brief review of the origin and progress of that art, he described the different methods used prior to the general adoption of the lead pencil, and discussed the systems laid down as the best means for carrying out the work by the various writers on the subject, examining them from the artistic and common-sense standpoints. He then proceeded to deal with the application of retouching to the various classes of negatives, including portraiture and architectural and landscape work, &c., and the means of legitimately forming or emphasising artistic effects. There were many, he said, who could not, or would not, recognise the legitimacy of retouching, but he regarded it as an essential in the production of successful portraiture, the object of the retoucher being to work in close sympathy with the operator, and to help him to carry out the artistic notion to which he first gives existence in the shape of a negative. Retouching was first introduced in the old wet plate days, when it was the custom to stipple out the blemishes in the negative with blue or neutral tint water colour; but the adoption of the lead pencil imparted a greater variety of possibilities

to be limited ultimately by the artistic feeling of the worker. This limitation was very ill-defined, and was shifted about in the most reckless manner to suit the temperament of the artist, or of the photographer employing him, or the whim of the customer. Various writers had laid down many and contradictory methods as being the only correct ones to be used in working; but he could not see that the results were artistic or natural or calculated to produce sound portraiture. There should be no such thing as a regulation touch; the shape and quality of a touch should be entirely governed by the shape and appearance of the blemish, and the touch should not be too positive and defined or the quality of the skin would be lost. Regulation touches would give what is called texture, but they would not give skin, and skin is a very important factor in every portrait. In the prevailing methods of working no attention was paid to this point, no thought was given to it—strong men, weak men, old ladies and young ladies, and even children, were all treated alike—there was only one skin on tap and all must have it. Delicate detail, fine modelling, artistic light and shade, were swept away by the retoucher for the sake of obtaining the polished surface so dear to him, resulting in cold, hard, and expressionless faces. Men were as susceptible as the gentler sex to the retoucher's flattery, and he hid himself on many occasions been called upon to completely alter a gentleman's nose, and even to reduce the beard in the back of a male sitter in whom increasing weight had marred the symmetry of former days. He thought that if retouchers exercised more judgment in their flattery, and brought more skill and thought to bear upon it, a better standard of work and opinion would be established, and one would not so often hear it said, with justice, that the best likeness of Mr. or Mrs. Snowden was taken by an amateur friend in his back garden, the reason being that, although it was a very bad photograph, it had not been retouched. In landscape and architectural work it was often possible to add an effect of light and shade not in the negative, or to emphasise an effect not already sufficiently powerful to assert itself, by washes of colour, papering the back of the negative, stumping in lights, &c. He recommended the adoption of the study of engravings, and said that by making a hobby of restoring engravings and mezzotints he had acquired a feeling for artistic beauty which was invaluable in his work as a retoucher, to say nothing of the attendant pleasure of the occupation. He had often wondered why amateurs, especially ladies of artistic tastes, had not gone in more seriously for retouching. He knew ladies who had "beautiful" likenesses, and who yet declared that they had not a likeness of themselves which they could leave to their family, and he expressed the opinion that there was a lot of money waiting for the professional or amateur who would supply that which should be at once a good photograph and a good likeness. A negative, he went on, held in itself an impression of the texture of the real skin, and the work of the retoucher would be made much easier, and would be infinitely better, if his touches were not so vivit and aggressive as to obliterate it. The slightest touch of the pencil would often soften a line so as to do away with the unfortunate expression which the majority of sitters assumed when they looked at a camera, and that, too, without taking away the natural characteristics of the face. If learners of retouching were taught to think, and not merely to make certain marks on the negative as a means of removing blemishes, their time would be saved and their work would be immensely improved.

The PRESIDENT regarded want of thought as the great fault of modern retouchers. He had himself made experiments in lighting, using a wax head, obtained from a hairdresser, and the result was a close approximation to the highly retouched photographs exhibited in the shop windows, i.e., the photographs showed nothing like skin and was devoid of expression. The retoucher, too, seldom had an opportunity of studying the original, and consequently worked more according to his idea of what the sitter ought to be than what he was really like.

Mr. REDMOND BARRETT said the loss of likeness was caused by a too lavish use of the pencil, and that the best result was always arrived at by the least amount of work; at the same time, he had never seen a negative which could not be improved by retouching, even though only a few touches were necessary.

Mrs. SNOWDEN WARD asked what description of pencils were recommended?

Mr. BARRETT said the best degree of hardness or softness depended, to a great extent, upon the peculiar touch of the user. Personally, he preferred a No. 3, a very safe pencil, with which almost anything could be done. With hard leads there was a tendency to increase the amount of work, and therefore there was a danger of overdoing it. The major blemishes should first be removed, and then, if the next lot in order of badness were taken out, little cure would be required. Freckles were quite easy to manage, but to absolutely fill them up would ruin the photograph, as it would make white spots. For landscape work the pencil was not suitable, and the best method was to use washes of colour, or to work on *papier minéral* fixed to the back of the negative.

Mrs. Gibbs, Dando and Snowden Ward took part in the conversation which ensued, and the proceedings closed with a hearty vote of thanks to the lecturer.

#### COMING EVENTS.

This was the last meeting of the session. The Society is now removing to its new home at No. 66, Russell-square, W.C., and its entry into occupation of a house of its own will be signalled by a *soirée* to be held on Tuesday next, June 27, at eight p.m., when the President and Council will receive the Fellows and members and their friends, together with any members of the affiliated societies who may be able to be present.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 15.—Mr. A. Haddon in the chair.

Mr. A. L. HENDERSON brought forward an interesting failure bearing upon the efficiency of the back-d plate. The negative was taken at Monte Carlo on a plate backed with a plain caramel preparation, which in turn had been covered with a piece of yellow paper, over about a third of the area of the plate, where the dark-slide springs would otherwise come into contact with the glass, the object, of course, being to prevent the stuff from sticking to the slide. He had used the same sample of caramel for twelve months at least,

and this was the first time that anything peculiar had occurred. Where the yellow paper had been the image was perfect, but where there was only the backing of caramel the negative appeared to be light-fogged. Could there have been some fluorescent action in the caramel, he asked as the plates had been backed for some length of time? The paper which supplemented the backing was that in which the plates were wrapped, and was of a dark orange colour.

The CHAIRMAN thought that, if fluorescence entered into the question, the effect would be a general action wherever the backing was present. Here, however, there was a distinct demarcation between the parts backed by the yellow paper and caramel together and the caramel alone.

Mr. H. VIVIAN HYDE said he had backed half a dozen plates in a similar manner, putting a piece of red paper of a smaller size in the middle. The parts of the negative backed only by the caramel were denser than those having the additional paper backing, a distinct outline showing. His idea was that the backing of caramel without the paper was not completely effective, hence the difference.

Mr. WALTER D. WELFORD read a paper upon

#### THE PAST AND THE COMING YEAR.

His remarks were based upon the minute-book records, and formed an epitome of the discussions which took place throughout the year on a few of the more prominent topics, such as printing methods and matters, negatives and films, developers and developing, toning baths and solutions (with the attendant questions of permanence and sulphur toning) and light and exposure. Mr. Welford awarded the palm for thoroughness of discussion and investigation to the subject of "Exposure in Shadow versus Diffused Light—Which is Longer?" but, on the whole, would describe the feature of the year to be "Toning," a subject which received a great deal of attention. As regards the future year, could not some idea be gleaned, he inquired, from the epitome here presented? Why was it that opinions were found to differ so widely, that we want to know this, that we do that, or cannot accept such-and-such a theory? The answer to this supplied an aim for the coming season, viz., a little painstaking investigation. There were many problems awaiting solution, and he asked that our motto for the coming year should be "Advance photography." In so doing we should further the interests of the Association and of ourselves, and so advance all along the line.

#### PHOTOGRAPHIC CLUB.

JUNE 14.—Mr. Hans Müller in the chair.

The ruling of the taking and viewing screens for the Joly process of photography in natural colours, upon which Mr. J. W. Mason addressed the last meeting, was again raised, special consideration being given to the difficulties which prevent the ruling of more than some 240 lines to the inch. It appeared that the running tendency of one of the liquid colours with which the ruling was done stood in the way of greater perfection being attained in this particular, but Mr. SNOWDEN WARD suggested that films of gelatine, suitably stained with the three chosen primaries, and piled up in a consecutive manner—red, green, blue, and so on—might be compressed into blocks, and thin cross sections cut away in the microtome. These sections, supported on glass plates, would present a series of rulings of a fine character, which might be used for the purpose under discussion.

Mr. G. W. TOTTEM raised the question of a safe light for the handling and development of isochromatic plates.

Mr. F. A. BRIDGE was averse to the use of direct light at all in his dark room, and arranged so that the light reaching the plate should be reflected light only, the rays passing the coloured glass to a white or yellow screen, and thence to the dish. His objection to isochromatic plates was on account of the poor light which they allowed one to use, but it was surprising how much more light could be employed of this reflected nature. He alluded to artificial light, which was, in his opinion, the best light to use on account of its constancy. He preferred not to use red glass at all if he could help it, and named Heile's photographic orange as capital stuff for dark room illumination, and one which he always used. By a little trial it should be easy to pick out a very serviceable glass, for glass was apt to vary in quality from a photographer's point of view, though in appearance it might be all that was required.

Mr. W. R. STRETTON mentioned that he knew of a case where Cadett's Spectrum plates were developed by the light of an ordinary ruby lamp burning low. He had developed isochromatic plates and rapid spectrum plates himself by the light of a ruby lamp, covered with canary medium (fabric), the plate being about a yard away, with no direct light falling upon it. There was no fog which could be detected.

Mr. FRANK HAYS always used the orange light of his Perfection lamp, made by Benham. The lamp was turned away, and the plate covered.

**Hackney Photographic Society.**—June 13, the President (Mr. W. Fenton-Jones) in the chair. The excursion reports and announcements showed that in this respect the Society was as flourishing as in others. In the monthly excursion competition marks were gained by Messrs. Selfe, Westcott, Stean, Gosling, and Hunt. A representative of the Vibe Camera Company showed one of the firm's new hand cameras, priced at 11. 18s. The chief features of the instrument were the method of changing, and the fact that a large number of plates or films could be carried. The size of the picture was four-and-a-quarter inches square, and plates of any size below this could be used if required. The chief item of the evening was a most interesting lecture by Mr. W. RAWLINGS on

J. W. TURNER, R.A.,

in which he observed that there was a natural desire to know something of the life history of men of mark; but, apart from the fact that about some famous men very little was known—as, for instance, Shakespeare—a search in that direction was often very disappointing, because it was often found that their lives differed very little from those of ordinary persons; and, again, genius

was often allied with eccentricity, and a study of the lives of some men of genius would reveal faults of character very disappointing to those expectant of special excellence in all things. To a certain extent this was true of Turner. The lecturer then sketched in detail Turner's life from his boyhood upward, and showed that Turner's aptitude for art revealed itself at an early age. He was the son of a barber in Maiden-lane, Covent Garden, and, in spite of his surroundings—or, as Hamerton considered, by reason of them, he rose to be one of the greatest of landscape painters. In the course of his artistic career he painted an enormous number of pictures covering a very wide range of subject and treatment. Mr. Rawlings recommended, as specially worthy of study by photographers, Turner's *Liber Studiorum*, a series of etchings, of which seventy-one were published.

**West Surrey Photographic Society.**—At the last weekly meeting of this Society, the Judges' awards at the late Exhibition, and in the Lantern-slide Competition, were given by the President of the Society. One went to Mr. Meadowcroft, for a seascape; one went to Mr. Hoad, for a landscape; while the Hon. Secretary (Mr. W. H. Wilshire) took, as well as an award for landscape, the winning award in the Lantern-slide Competition with four slides of especial merit, and on which the President especially congratulated him.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE COPYRIGHT ACT.

To the EDITORS.

GENTLEMEN,—I thank you for your articles on the proposed Copyright Amendment (?) Act now before the House of Lords. I quite agree with you that, if carried in its present form, it will inflict great hardship upon professional photographers and publishers, and no time should be lost in getting up agitation against it. Permit me to suggest that your firm are the most likely people to send out a form of petition against the Bill to all the professional photographers in the United Kingdom, asking for signatures.

Of course, this will involve some trouble and expense; but as it is one of the features of modern journalism to embark upon any enterprise that is calculated to lay their subscribers and patrons under additional obligations and appreciation of the services rendered to the profession by your JOURNAL, it would pay you indirectly. But, even if you are not inclined to incur the expense, I am sure thousands of photographers would gladly subscribe the small amount necessary to recoup you.—I am, yours, &c.,

J. R. BECKETT.

Photo Studio, Fern Bank, Yeovil, June 19, 1899.

[We are obliged to our correspondent for his suggestion. Such a matter, however, is more properly to be dealt with by representative institutions. It will be seen by the following circular that the Copyright Union and the Royal Photographic Society have the matter in hand.—Eds.]

"ROYAL PHOTOGRAPHIC SOCIETY.

"66, Russell-square, W.C.,

"London, June 19, 1899.

"The Photographic Copyright Union have represented to the Royal Photographic Society the urgent necessity for an expression of opinion of the Society and others interested in maintaining the present status of photography as a fine art, with reference to the new Copyright Bill.

"You are earnestly requested therefore to attend a meeting at 66, Russell-square on Wednesday, 21st inst., at 8 p.m., the Earl of Crawford in the chair, when a resolution will be proposed as to the position of photography in the Artist's Copyright Bill now before Lord Monkswell's Committee in the House of Lords.

"J. WATERHOUSE, Colonel I.S.C.,

"Hon. Sec P.R.S."

### A PARTNER WANTED.

To the EDITORS.

GENTLEMEN,—I trust you will forgive the liberty I have taken in writing to you; but, as this is a matter of business, no doubt you will kindly excuse me. You will see by this letter that I am a photographer and am wanting a partner, so I thought you may be able to help me, or, if not, you may know of some one who could; if so, you would do me a great favour by handing this letter to any one you may know of.

I am an Englishman and have been in this country for ten years, and have been in business for myself for five years, having bought out a man who had been here some years. During the time I have been here I have done well. There is only one other photographer in this town, but, as his work is inferior, I find him an advantage, as he keeps a good man away. I commenced learning my profession with one of the leading firms at Plymouth, Devon, and I was there for three years before coming out West. Now that Calgary is fast going ahead, I want some one in with me so that I shall be able to extend business. I would

prefer taking a young man with a fair knowledge of the work, although I would not mind taking a good amateur, providing that he is willing to work and improve.

The net profits last year were \$3500, and this was when the country was suffering from a general depression. There has now been quite a change, owing partly to the extension of the Canadian Pacific Railway Company's works, and also the gold rush North made no small difference. The capital required to purchase a half share would be 4000. If you know of a young gentleman who is willing to work and keep steady, I am sure that in a few years he would not regret coming out West.

Trusting that I shall have the pleasure of hearing from you,—I am, yours, &c.,

J. M. LOWNDES.

Calgary, Alberta, N.W.T., Canada, May 20, 1899.

[We often have applications from young photographers desirous of engaging in business abroad. The foregoing letter seems so straightforward that we have no hesitation in giving it publicity, with the view of bringing it to the notice of likely candidates for the partnership.—Eds.]

### THE MUTOSCOPE.

To the EDITORS.

GENTLEMEN,—In one of your editorial paragraphs in your issue of the 16th inst., where you refer to the dividend paid by the British Mutoscope and Biograph Company, you very appropriately put the question, "Why do not some of our home manufacturers have a 'cut in' at the latter branch (The Mutoscope), we wonder?"

If you can see your way to insert the following by way of a supplement to your question, I have no doubt but many more will wonder as well as yourselves.

Before the above Company took the field, I invented and protected a mutoscope far superior to anything in that line yet brought out, and yet, for want of men of capital and enterprise to place it in the field, it is held in abeyance. I have built a crude model, which has been seen by one of the leading photographers of London, and by gentlemen in Glasgow (including opticians), who have pronounced it the best among mutoscopes, notwithstanding its home-made construction.

The pictures are not paralysed, as in other mutoscopes, but are absolutely steady, while the illusion of a living picture is perfect.

With the above to supplement your question, one may well wonder at no "cut in" being made for a share of the good things now going in dividends.

Thanking you in anticipation for space accorded,—I am, yours, &c.,

THOMAS ANSBORO.

277, Swanston-street, Bridgeton, Glasgow, June 17, 1899.

[Perhaps the publicity given to our correspondent's letter will be the means of inducing some enterprising manufacturer to inspect the model with a view to taking it up. Photographers and opticians are possibly not the best judges of the chances of commercial success which a mutoscope may possess. We heard some time ago that an English Company with a capital of 30,000*l.* was about to put mutoscopes on the market.—Eds.]

### IN REPLY TO "FREE LANCE."

To the EDITORS.

GENTLEMEN,—Evidently "Free Lance" is still in the archaic stage of photographic art, and like the child, left to draw for its own amusement, represents in profile only, the objects he wishes to delineate. Our critic cannot conceive of a point in motion impressing a plate in the camera with anything but a line, consequently foreshortening is excluded from his conception of photographic representation, and horses in gallop must be photographed broadside on. In reply to my second query "Free Lance" says he "should not attempt to show that every part of a horse in gallop moves at uniform velocity, for they do not." "Free Lance" may find part of the solution of his conundrum in this admission. With wit on a par with the strength of his criticism, he says "the fetlock might be looked upon as the portion whose progressive motion at times was slowest," and suggests "the fetlock of a cart horse rather than a race horse for manifestation of hair." Well, "Free Lance" chose the speed of the animal. If he backs horses, which only move half an inch in  $\frac{1}{100}$  second, I am not surprised at his want of success.—I am, yours, &c.,

P. EVERITT.

### THE NATIONAL PHOTOGRAPHIC AND ALLIED TRADES' EXHIBITION, 1900.

To the EDITORS.

GENTLEMEN,—Will you kindly permit me to announce, through the columns of your valuable JOURNAL that the second trade exhibition of photographic and scientific apparatus and sundries will be held early next year. The Portman Rooms, Baker-street, London, W., have again been secured, and the Exhibition will open on Friday, April 27, and close Saturday, May 5.

Arrangements have been made for increased space, and some thirty or more stalls, in addition to the spaces occupied last year, will be available for exhibits. The entertainments, lectures, and musical arrangements, which proved so attractive on the last occasion, will be repeated, and special attention is being given to this department in order to make the Exhibition, if possible, even more attractive to the outside public. The magnificent suite of rooms are specially adapted to a display of technical apparatus, and the Portman Rooms are easily accessible from all points of the metropolis. Any suggestions from your readers will be much appreciated, and, if practicable, will probably be adopted.

Most of the firms who exhibited last year have already intimated their intention to again take space, and several other firms have also expressed a desire to be represented. The prospectuses and application forms for space will be issued very shortly, and spaces will be allotted strictly in rotation as applications are received, the only exception being that former exhibitors will have first refusal of the spaces previously occupied by them.

I trust that an early announcement of these dates will prevent clashing with any other exhibition, and that exhibitors will thus be free from the inconvenience of having two displays to attend to at the same time. It is of the utmost importance that intending exhibitors should reply to the prospectus immediately upon receipt of same, in order to avoid disappointment.—I am, yours, &c.,  
pro ARTHUR C. BROOKES, Secretary.

B. C. P.

15, Harp-alley, Farringdon street, London, E.C., June 20, 1899.

## INTERNATIONAL EXHIBITION, PARIS, 1900.

To the Editors.

GENTLEMEN,—In reply to my application for space to exhibit at Paris, 1900, I received the following reply, dated August 15, 1898:—

"I beg to acknowledge the receipt of your application for space in the British Section of the Paris Exhibition, 1900, and to inform you that it will receive due consideration," &c.

After due consideration the following was forwarded to me:—

"In reply to your letter of the 12th inst., I beg to inform you that, in consequence of the limited space available for a display of photographs in the British Section of the Paris Exhibition, 1900, it has been decided to form a collective exhibit of photographs. This collective exhibit will be made up, to a large extent, of selections from the Autumn Exhibitions of the Royal Photographic Society and the Camera Club. Those who have made application for space and do not send specimens of their work to these Autumn Exhibitions will, if the Committee consider it necessary, be asked to submit a few specimens of their work, in order that a selection may be made from them for the Paris Exhibition.—I am, yours," &c.

Now, I worked for the following International Exhibitions: Vienna, Brussels, Lyons, and two Paris; but in neither case did I hear of the exhibits having to be submitted to a special committee; on the contrary, each applicant had free permission to exhibit his own choice; only, if the application for space was more than the allotment from the Exhibition Committee, the space applied for was cut down.

But here one has to depend on the Royal Photographic Society and the Camera Club. Who are they? Amateurs mingled with some scientific men, good men, too, but who ignore all professional photographers.

I, as a professional, was under the impression that, in this case, I should not be interfered with—*Impressionism*—and I wonder if the Paris Exhibition is promoted to further the amateur or the professional? Another question: If the space is limited, why is a selection made from photographs whose originators have not applied for space at specified time? Or must I conclude that this collective exhibit will only compete for one award, and that the single individual is not allowed to take his own chance?

And why should I show my intended exhibit beforehand, to give others the idea to copy me?

What is your opinion? I should be most pleased to hear your interpretations of the above, as you are more *au courant* with photographic life, whereas I am not personally acquainted with many professionals.

An enlightenment through your valuable paper may be of great benefit, not only to me but also to other intending exhibitors.—I am, yours, &c.,

SILVER MEDAL, PARIS INTERNATIONAL, 1889.

[We believe that the joint Committee of the Royal Photographic Society and the Camera Club is charged with the duty of selecting a thoroughly representative collection of non-competitive work for exhibition at Paris. The matter will not be taken in hand until the autumn. What course the Committee will pursue in making the collection we cannot tell. It is perhaps regrettable that individual exhibits are not invited for the Paris Exposition, but it is to be hoped that every facility will be given to those whose work is good enough to form part of a representative display to be included among the exhibitors.—EDS]

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

H. M. MACHHEAR.—It is against our rules to give recommendations of the kind you ask for. We suggest that you procure our ALMANAC for 1899, in which almost every make of hand camera is figured and described. This should enable you to select an instrument fulfilling your requirements.

DISCOLOURED PAPER.—A. BRIGGS says: "I have a quantity of —'s P.O.P. which, with age, has become discoloured, and this discolouration shows in the prints after they are toned and fixed. Can you tell me of any means of preventing this, as I have a large lot of the paper which I bought as a 'job lot'?"—If the paper is discoloured as stated, there is no remedy.

LUBRICANT.—REX says: "I am using a lubricant recommended in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC (alcohol and Castile soap) for albumen paper. Can you please tell me of any other which would produce a better gloss on that paper?"—We know of no better lubricant than that given. The object of the lubricant, however, is not to give gloss, but to enable the print to pass easily over the burnisher. The gloss depends upon the burnisher, not the lubricant.

YELLOW STAIN ON NEGATIVE.—J. HUGHES says: "A negative has been brought to me from which a bromide enlargement is required. About one-third of its surface is covered with a deep yellow stain, presumably from imperfect fixation. Will you kindly inform me how the stain can be removed; also if imperfect fixation is the cause? The negative was taken about three years ago."—Under the circumstances we do not think the stain can be removed. An immersion in a fresh solution of hyposulphite of soda for a few minutes might be tried, however. Probably imperfect fixation is the cause of the stain, but we could not say for certain without seeing the negative.

FACTORY ACTS.—P. R. O. writes: "At my printing place I have six female assistants, a man, and two lads at work printing and mounting. I have been told that the place comes under the Factory Act and the young people must have a half-holiday a week, and I must be subjected to the other inconveniences of this abominable Act, but I don't believe that photography comes under it. Can you tell me if it does?"—Certainly it does. Why should there be any exemption in photography more than there is in any other business? The Act was framed to protect young persons from being overworked, and to secure for them some little time for leisure or recreation, also proper places to work in.

PORTRAIT.—G. F. writes: "1. Can a ten-inch objective, such as is supplied with Hume's Cantilever, be any use for studio work? 2. Is P.O.P. suitable for opaline work, and, if so, what strength and temperature of gelatine solution is necessary? 3. What is the best preventive of blisters (which appear after fixing) which occur on collodio-chloride paper?"—In reply: 1. Yes, but it will probably require to be stopped down. 2. Yes; rather weaker than is used for albumen paper. The temperature should be such as will just keep the solution quite fluid. It is not desirable to use it much hotter than will suffice to do that. 3. There ought to be no blisters with the paper if it is all right. Some have recommended putting the prints in a weak solution of alum, and then well washing prior to toning, when the paper is prone to blisters.

MOUNTING ENLARGEMENTS.—DEXTROSE says: "I have a considerable number of 12 x 10 enlargements to mount on India-tint plate-mark mounts, and have been bothered very much when mounting by the edges curling up especially after they are dry. I use a simple starch paste, damp the enlargement first by rubbing the back with a wet sponge, then allow it to lie for a minute and apply the starch and mount. I don't know if this is the usual method of procedure, but I believe most professionals use Glenfield starch simply. Can you give me any hint how to prevent the edges curling?"—There may be several causes for the trouble. The prints may be made too wet, to begin with, the starch paste too thin, or it is not applied thickly enough at the edges of the prints, or they are not pressed in sufficiently close contact with the mounts. Glenfield starch is a good one, but any other good starch will answer. See that there is a good coating of the starch on the extreme edges of the prints and that they are well rubbed down when mounting.

AIR BUBBLES ON PRINTS. F. RALPH says: "I enclose a print on P.O.P., which you will see is much discoloured and marked with air bubbles. This seems to occur in the washing water between toning and fixing. I have been troubled about this for a very long time, but cannot locate the cause. I have a suspicion the water used, which is from a spring well, is unsuitable for washing gelatino-chloride paper. Perhaps I ought to mention, the makers of the paper advise us, the toning bath or washing water is where to find the cause of the trouble, but I have satisfied myself the toning bath is all right; but how can I test the water?"—The markings are clearly due to air bubbles adhering to the paper, either in the first washing, by preventing the water having free action in removing the free silver, or while in the toning bath, and thus causing uneven toning. The remedy is to see that no air adheres at any stage of the work. We do not think the water itself has anything to do with the trouble. This may, however, be tested by treating one batch of prints with the spring water and a corresponding one with river or rain water.

## EX CATHEDRA.

It was not to be expected that the meeting called, at one day's notice, for last Wednesday week by the Royal Photographic Society to protest against the attempt now being made in the Copyright Bill at present before the House of Lords to exclude photography from the legal enjoyment of the status of a fine art which was conferred upon it in the year 1862—it was not to be expected that such a meeting, fixed, too, for a midsummer evening, would be a very large one; nevertheless, when Lord Crawford, President of the Society, took the chair for the first time in the meeting-room of the beautiful and stately new house of the Royal Photographic Society, he was well supported by some of the foremost photographers of the day. We noticed amongst those present Mr. Alfred Ellis, Mr. Lyddell Sawyer, Mr. Warwick Brookes, Mr. William Grove, Mr. W. E. Downey, Mr. J. J. Elliott, Mr. J. Hubert, Mr. H. N. King, and Mr. S. H. Fry. Mr. Frank Bishop and Mr. Howell, Chairman and Solicitor of the Copyright Union, were also present, and the attendance included many other gentlemen directly or indirectly interested in copyright.

LORD CRAWFORD expressed great pleasure at the fact that the first meeting in the new home of the Royal Photographic Society should be called for the purpose of defending photographic copyright. In the course of a few introductory observations the President said he could see no reason why the copyright protection photographers had enjoyed for thirty-seven years should now be taken away from them. His Lordship was followed by Mr. Howell, the Solicitor of the Union, who after pointing out that on the whole the present law of photographic copyright was satisfactory, gave the meeting a lucid statement of the points of principle attacked by the new Bill. These have already been dealt with in our pages. Mr. Howell also repeated the substance of his evidence as given before the Select Committee of the House of Lords now sitting on the Bill; this, too, we summarised last week. But Mr. Howell made one or two very interesting observations upon some other aspects of the Bill which merit notice.

\* \* \*

THE proposed Copyright Bill, which seeks to rob photographers of the rights they have enjoyed, is, it appears, the work of an artistic "cave" which met recently in St. John's Wood. It is composed of Academicians; and, seeking to de-grade photography below the level of photo-mechanical work the promoters of the Bill are said to be animated by jealousy of photography. Lord Herschell's Bill, which was introduced and dropped last session, practically left photographic copyright undisturbed. Besides the attempt of the new Bill to separate photography from the fine arts, Mr. Howell was emphatic in his objections to compulsory registration, which it seeks to enact. He was hopeful that the evidence which was given, and the protest which he suggested should be passed by vote that night, would have the effect of influencing the Select Committee in favour of photographic copyright.

\* \* \*

FOLLOWING Mr. Howell's statement there was a lengthy discussion on points of detail. Two facts were clear. The meeting was resolutely opposed to the separation of photography from the fine arts, and to compulsory registration. Indeed, the prevailing aspiration was that photographic copyright should be left as it stands. In the end, on the suggestion of Lord Crawford, the following resolution was unanimously agreed to: "That in the opinion of this meeting it would be

an injustice to those practising and utilising photography to interfere with the rights and privileges enjoyed by them under the Fine Art (Copyright) Act, 1862." It was intimated at the close of the meeting that the Bill has not the slightest chance of passing through Parliament this session. The resolution we have quoted is to be brought before the Select Committee at the earliest opportunity.

\* \* \*

THE Select Committee held another sitting on Monday last. Mr. Frank Dicksee, R.A., one of the witnesses, said he represented the Royal Academy. A long discussion then took place on Clause 4 of the Bill, by which it is proposed to confer the copyright of the work on any person who "employs another for valuable consideration to make any photograph, or to make or assist in making from the original design of the employer any work of fine art or cast from nature." A painted portrait, the witness explained, would not be included in this category, but the copyright would belong to the author, and, although the "employer" could do what he liked with the original which he had purchased, he could not have it reproduced without the artist's consent. The principle of the Bill, the witness explained, was to give copyright in every case to the author; Clause 4 also gave certain rights to the employer which were rather exceptional.

\* \* \*

THERE WAS a meeting of the Council of the Photographic Convention of the United Kingdom on Thursday, June 22, at which the final arrangements for the Gloucester meeting were discussed. The civic authorities are preparing to give the members a hearty welcome. Not only will the Mayor and Corporation officially receive the Convention, but, in other respects, civic recognition and hospitality will also be extended to members. Mr. Crooke (the President) will probably have on view a collection of his own portrait work. We understand that a very large and beautiful display of platinotype prints by the Platinotype Company will form a feature of the Trade Exhibition in the Guildhall. A great many of the examples, chiefly reproductions of celebrated pictures, have already been shown to us; they will form quite a pictorial exhibition in themselves.

\* \* \*

THE Council drew up a list of nominations for Council for the ensuing year, and wisely removed the names of a number of gentlemen who have figured on the executive for years, but have not considered it their duty to attend a single meeting of the governing body. One or two frivolous complaints about details of administration also came before the Council Meeting. The Convention has recently been the butt of criticism at the hands of a few gentlemen who do absolutely nothing to promote the success of the institution of which they are members, but who seek to atone for this deficiency by the noisiness of their grumbles. However, this sort of thing is best dismissed with a smile. The trade space in the Guildhall has been fully let. Mr. Child Bayley is taking considerable trouble to ensure the success of the Monday evening colour-photography display by means of the projection lanterns to be worked by the able hands of Mr. R. R. Beard, so that local visitors to the inaugural ceremony will have given them a reliable and accurate demonstration of all that has so far been practically achieved by the recognised processes for photographically reproducing colour. As for the more festive items in the

Convention programme, these are bound to be successful, and only fine weather is needed to impart a world of enjoyment to the excursions. Personally, we are looking forward to shaking the hand of many an old friend of the JOURNAL during Convention week.

\* \* \*

MR. C. T. JAGO, of 182, New Kent-road, S.E., to whose process of colour photography, by means of rubbing pigments into a half-tone block, we referred nearly a year ago, writes us as follows: "In *Ex Cathedra* of your issue dated July 29 of last year you noticed my 'idea in colour photography,' for which I had obtained a patent. I am hoping to make some practical use of the idea for a novelty in coloured miniatures. I have a portrait reproduced with a 200-line Levy screen, and, when coloured, the grain is hardly discernible and the pastels are almost a fixture. I think, with a still finer grain, the colours would be quite fixed. Of course, I shall not want the public to know how the picture is produced, except that it is a portrait enamelled on copper, with the colours inlaid by hand; so I think the dot screen would help to hide the fact of its being a process plate. One advantage I find in this kind of picture is that it is impossible to lose the likeness in colouring, the detail being all on the surface and the colours below."

\* \* \*

IT WILL be seen by our Patent News this week that the abnormal number of seventeen applications for photographic patents was made between the dates of June 12 and June 17. Of these two relate to colour photography, and stand in the name of Dr. Gustave Selle, whose processes have formed the subject of considerable comment and curiosity for some time past. We understood that the Company formed to work his patents and processes was to have been introduced to the public before last Easter. To go back to our subject: It would be interesting to know why the middle of the month of June should witness the outbreak of so much activity amongst photographic patentees. Two of the applications relate to cameras. He is a clever man indeed who, in these times, can really "improve" a photographic camera, perhaps the most patented article, after the cycle, of modern times.

\* \* \*

LAST week we printed a little article by Mr. F. G. Willatt, entitled "Photography in Dots." The author advocates the use of an irregularly grained screen in contact printing, arguing that by such means we obtain a general effect of roughness of texture without actually destroying the sharpness of the picture. Some of the photographs printed through such a screen, which Mr. Willatt showed us, are decidedly interesting and attractive, in virtue of the distribution in the lights and half-tones of this effect of non-mechanically obtained "screeniness." The results produced in this way are most artistic. Mr. Willatt, whose address is 101A, Fulham Palace-road, Hammersmith, W., prepares the irregularly grained screens to which we have referred, and they may be had of him at a few shillings each.

\* \* \* Two short editorial articles this week touch on the subjects of "Ferrous-sulphate Solutions" and "The Permanence of Silver Prints," the latter being a matter of the highest importance to photographers.—Mr. Alfred Watkins contributes a further article on "The Speed-marking of Plates," in the course

of which he makes out a case, and pleads, for uniformity in the speed-marking of plates.—There is a note by Dr. Eder, upholding the subhaloid theory of the latent photographic image.—Amongst other articles are two which pressure on our space has obliged us to hold over for some weeks. One is by a well-known American photographer, Mr. W. H. Rau, who briefly describes how to reproduce and enlarge negatives, using gelatine plates for the purpose.—The "New Metric Weights and Measures," as promulgated by a Governmental Order in Council, are reprinted from the Royal Photographic Society's *Journal*. They should be useful for reference, and be kept permanently at hand on that account.

### THE PERMANENCE OF SILVER PRINTS.

THE extract from the *Photographische Chronik*—which we gave last week—on the comparative permanence of silver prints by different processes must not, we think, be taken as conclusive evidence that emulsion papers, with a baryta coating, yield less stable results than papers without it. One thing noteworthy in connexion with the writer's experiments is that all the prints were fixed, for the same time, in a one in twelve solution of hyposulphite of soda. Now, one in twelve is an exceedingly weak solution. In this country the strength of the fixing solution in general use is just about double that strength, namely, three ounces to the pint. It is quite conceivable that, if the free silver in the emulsion forms a compound with the vehicle that secures the baryta to the paper, the weak solution of hypo does not, in the time given, thoroughly get it into the soluble condition to be removed by the washing waters. In the case of the plain papers, of course the fixing bath, weak as it was, had not the baryta coating, and its vehicle, to deal with, therefore a longer immersion of the baryta papers was necessary to make the tests reliable.

The sulphate of baryta, *per se*, may be considered an inert material; but, as we have said before, the sizing material with which it is mixed may have a deleterious action on the silver image. In the experiments quoted in the *Chronik* collodion-chloride is mentioned as one of the papers that changed quickly. Now, it is an established fact that there are many collodion-chloride prints as good now as when they were first produced, more than thirty years ago, and until recently this process was looked upon as the most permanent of all the silver processes, by reason of the fact that the collodion is an inert material, and does not form a compound with silver as does albumen or gelatine. It must be mentioned, however, that in the early days of this process the emulsion was always applied to plain paper, or rather one coated with arrow-root, and not with a thick baryta coating.

At the present time, unfortunately, the manufacture of photographic papers is practically in the hands of two firms, who have recently combined, and the surfacing of them is also in the hands of three or four concerns, who have also combined, hence the emulsion-paper makers, whether gelatine or collodion, are at their mercy, and must take what they choose to send them, whatever the baryta coating may contain. It may be possible that the most desirable vehicle for the baryta, so far as photography is concerned, is not the best for securing an even coating, and therefore is not employed, and so much the worse for emulsion processes.

It is to be regretted, as we have said on previous occasions, that English paper-enamellers have not taken up the surfacing

of paper for photographic purposes, for at the present time this seems to be a monopoly in the hands of two or three. German firms, who have now formed "a ring," thus avoiding competition amongst themselves.

### FERROUS SULPHATE.

In last week's *Chemical News* will be found an extract from a paper by Mr. W. S. Meyer in the *Journal of the American Chemical Society*, entitled "A Convenient Method of Maintaining Reduction of Ferrous Solutions," the writer stating he calls attention to it from its being "economical, convenient, and effective, and (so far as I have been able to ascertain) new in this particular application." From the point of view which we always take of the desirability of uniformity in all stock solutions, and, indeed, in all chemicals, it would be a desirable thing to keep solution of ordinary sulphate of iron without its absorbing oxygen, and so losing its uniformity, an absorption being soon shown by the loss of the beautiful apple-green tint of fresh-made solution. The remedy, however, is scarcely a practical one for photographic purposes, for it consists in strongly acidifying the solution, to the extent, indeed, of adding ten per cent. of strong sulphuric acid to a ten per cent. solution of the sulphate of iron, and also the addition of free iron in the shape of small tacks; in other words, as much sulphuric acid as sulphate of iron with a packet of tacks thrown in. Photographers using the old iron developer are accustomed to add an acid, but they, as a rule, prefer acetic acid, and they further consider that the absorption of oxygen to the extent of making the solution almost red is a distinct advantage. In the strict sense of Mr. Meyer's process, it is not new. Many years ago, when gelatino-bromide plates were unthought of, the pure sulphate of iron usually obtainable quickly used to lose its beautiful green colour, and become oxidised to the rusty stage; but there was also on the market—not commonly sold, it is true—a form of sulphate known as "permanent," small, prettily shaped crystals, of a yellower green than usual, that never changed colour. It was generally understood by experts in chemical manufacture that these crystals were formed in an extremely acid solution of the salt, enough acid being present in the mother liquor to keep the crystals pure for an indefinite time, Mr. Meyer's process being thus rather belated.

**The Metric System.**—Sooner or later, there is little doubt, the metric system of weights and measures will be universally adopted here. Last week, in the House of Commons, in reply to a question as to whether our trade with South America is not suffering materially because the metric system is not compulsorily adopted, Mr. Ritchie replied that there is no reason why any trader or manufacturer in this country may not carry on his foreign trade by metrical weights and measures. In reply to another part of the query as to whether he would facilitate the adoption of the metric system in this country by using metrical weights and measures in the Government departments, the President of the Board of Trade said he was in communication with some of the Government departments on the subject. We are pleased to see that the adoption of this system is increasing amongst photographers by reason of plate-makers and others quoting their formulæ under both the metric and the ordinary systems. It would be still more facilitated, as we have said on more than one previous occasion, if dealers would put upon the market measures graduated on both systems—metric on the one side, and the English on the other—so that they would serve equally

as well for the one as for the other. The same with the weights. If the gramme weights were stamped also with the equivalents in English grains, they would then serve the dual purpose like the measures. That would greatly facilitate the general adoption of the metric system amongst photographers, particularly as most of the formulæ we get from abroad are given according to that system.

**The Turner Exhibition at the Guildhall.**—A few weeks back we advised photographers not to miss the opportunity of visiting the exhibition of some of Turner's finest works—paintings, drawings, and etchings—now open at the Guildhall, as the opportunity may never occur again of seeing such a collection, drawn from so many private collections. On a second visit, paid last week, we learn that, during the short time the Exhibition has been open, it has been visited by close upon 200,000 persons. The Exhibition is open daily, and on Sunday afternoons, and the admission is free. A very explanatory catalogue of the pictures is sold at the doors for 6d. In addition to Turner's work, there are some fine pictures by contemporary artists—Gainsborough, Eddy, and others.

**Hampton Court Pictures.**—Kingston-on-Thames does not like the idea of a number of the pictures in Hampton Court Palace, including several of Raphael's cartoons, being removed from there to Kensington Palace, and the Town Clerk has written to Her Majesty's Office of Works on the subject. The reply received was to the effect that the Corporation of Kingston are apparently not aware that the pictures at Hampton Court Palace are the property of the Sovereign, and are exhibited to the public at the pleasure of Her Majesty, who has exercised her right to add to or withdraw from the collection from time to time, and no question ever had been, or ever could be, raised as to the free exercise of this right. Of course the removal of the works is a loss to Hampton Court Palace, but a gain to Kensington Palace and London people, as the latter Palace is now to be open to the public, and those wishing to see the pictures will not have to make a journey to Hampton to do so. Raphael's cartoons have not been much photographed; but some years ago—thirty or more—they were admirably reproduced on a large size—24×18, if we remember rightly—by Mr. Thurston Thompson.

**An International Beauty Contest.**—There has been an International Beauty Contest in Paris, and the principal prize has gone to a theatrical lady, and her photograph has, no doubt, been in large demand since the award. We are told by the Central News that some American society women were in the competition; also a few Italian, Spanish, and Belgian women. It would seem that no English competed, and one cannot be sorry for it, for it would be degrading. There was once a beauty show in this country, but then it was confined entirely to barmaids, and we are pleased to say the show was but a limited one, and that it was not repeated. So far as we are concerned, we should like female beauty shows to be confined to the other side of the Channel, whether they be international or otherwise. In all exhibitions and shows at which prizes are given they do not always give universal satisfaction; we know that from photographic as well as other exhibitions. It would be exceedingly interesting to know if the Judges' awards at the Paris contest gave universal satisfaction to all the fair competitors. If they *did*, it makes good an old adage, "They manage things better in France."

#### SPEED-MARKING OF PLATES.

At the very mention of the word "speed" the controversialist pricks up his ears in anticipation of the fray, the plate-maker—most placid of good fellows at ordinary times—changes his visage and puts on his invisible armour, and the average reader turns over to the next page with an impatient shrug. Let me therefore hasten to explain that I am not about to enter into the vexed question of the definition of speed, or the means by which it may most accurately be expressed. The time for this is not yet ripe, although we may be a little advanced beyond the knowledge of

1894, when the Plate Speed Committee, appointed by the Royal Photographic Society to investigate and report on the matter, were obliged to separate without definite conclusion, because no two members were agreed in their ideas of the primary definition of speed.

It is rather of the commercial difficulties of speed-marking that I wish to speak, and of the impediments in the way of plate-users getting uniform and reliable information on the point when they buy a box of plates. Who can say that the discussion of these difficulties may not tend towards their ultimate removal?

What the average photographer understands as speed is the outcome of his experience and wants. He is probably using a certain plate, and has a pretty good idea of the exposure necessary to get the results he requires. He wishes to buy another batch of the same brand of plate, and wants to know definitely whether he will have to reduce or increase his exposures, knowing by sad experience that the advertising announcement of "always uniform" is a weak crutch to lean upon. For these reasons it is of the greatest value to have marked on the box a speed number which he knows is the result of an actual test of that batch of emulsion. Or the want is still more urgent if he wishes to try a new brand of plates, and does not feel inclined to spend time and plates in finding the speed by "trial and error." In this latter case it is of the greatest importance that the speed number should not only be the result of an actual test of that batch, but that it should be comparable with the speed numbers of other makers. If both these conditions are not met, speed numbers become a trap to create error, instead of a means of preventing them.

The need for definite speed numbers is more strongly felt as photography tends to become an exact science. Time was when all were content with vague standards of value, such as a "medium-size stop" or a "fair light;" but now, with the increasing use of definite methods of calculating exposures and the adoption of the actinometer as an every-day instrument, it becomes important to apportion an exact value to all the factors which influence an exposure.

It is greatly to the credit of those clever pioneers, Messrs. Hurter & Driffield, that from the first they have done their best to keep speed numbers uniform, and have also tried to prevent their being used as a trade designation of the approximate speed of a maker's brand, instead of an expression of an actual test of that particular batch.

I have purchased two boxes of the same brand of plates from different sources about the same time. Both boxes bore the same H. & D. speed number, printed on the label in such a way as to suggest that it was a stock label, which always bore that speed number for that brand; and, when I tested these two boxes side by side with the Hurter & Driffield method, one was much higher in speed than the other. It is this kind of procedure which brings discredit on speed numbers.

It was the same kind of procedure which brought discredit on the Warnerke speed numbers. Makers printed on their lists and on their labels the statement that their plates were, say, 25 Warnerke, and users found that, although different batches of the same plate varied (as, in the ordinary course of things, they would) in speed, the same numbers continued on the boxes. The Warnerke plan, as most readers will know, is based on ascertaining the smallest light impression which will give a developable image. I am inclined to think that it has been condemned by some on insufficient evidence. It was found that different numbers could be read from the same plate by variations in development; but we now know that the same fact applies to any plan of speed-testing, and there is room for further trial of the plan, not of necessity with the same apparatus, in the light of recent knowledge of the effect of development of speed and of the relation between the time of appearance of image and completion of development.

There are two great obstacles in the way of reform in speed-marking. The first is the insane demand by the public for the highest speed, and the absurd idea that of two plates the highest speed is the best. All practical men know that too often the increase of speed is at the expense of quality in the plate, and that in nine cases out of ten the subject does not demand an extremely rapid plate. But the result has been that makers have all thought it necessary to advertise "the fastest plate made," and the adoption of an accurate and uniform speed system would somewhat clash with this.

The other obstacle is the fiction that a certain brand of plate is always the same speed. When a maker has adopted this fiction in his advertisements, it is a little difficult for him to adopt an accurate system of speed-testing and show the public that his plates do vary in speed.

But those who have had the courage to mark each batch with the speed given by actual test save themselves ultimately from very serious difficulties. For instance, a firm has announced its different brands to

be relative speeds of, say, 1, 2, and 4, and after the manner of the craft intimate that those who say otherwise are beneath contempt. But in the course of time it is desirable to improve one of these brands, or the head plate-maker goes to another place or in some other way a change comes about. What are the poor people to do with all their circulars tying them down to this ratio, and their exposure tables and slide-calculators (called meters by a strange stretch of fancy), all based on the 1, 2, and 4 ratio? They dare not announce a change, or they would bring on their devoted heads shoals of letters of the "how is this" type. How they wish they had earlier adopted the more satisfactory course of acknowledging that, in the natural course of plate-making, speeds will vary, and, if the user is only posted up by the speed number on the box, the variation will be no inconvenience to him.

A third difficulty lies in the fact that what the practical man knows as speed is not a simple but a compound value, built up of at least two qualities, the detail giving quality and the density giving quality. Let me illustrate this by supposing that two photographers are given two brands of plates of different character to test. The one man, who judges only by the detail-giving quality, pronounces A to be a much faster plate than B; the other man, finding that with equal exposures B develops into a vigorous printing negative with much greater facility than A, pronounces B to be the most rapid. Both men are right according to their own standpoint.

It should never be forgotten that the Hurter & Driffield speed numbers relate solely to the detail-giving quality. Two different makes of plates may show the same speed number, and with equal exposures one may develop with ease to printing density and gradation, while the other seems scarcely capable of doing so. The system is quite capable of expressing the density-giving quality as a separate value, but the information is seldom given.

These two investigators (whose names, like King Charles's head in Mr. Dick's memorial, continually crop up in all that is written on this subject) have rendered a great service, by showing clearly that the two qualities I have mentioned must be treated as distinct matters in accurate speed-testing.

I am aware that, in advocating the speed-marking of each batch of plates, I am somewhat open to a charge of inconsistency. "Since 1890," I can hear a critic say, "you have been issuing a speed list of plates, in which you claim to give the relative speed of all plates sold; how can this be accurate if plates vary from time to time?"

My answer is that, although such a list must of necessity be imperfect, it is a need arising out of still more imperfect circumstances. When I introduced an exact plan for calculating exposures, there was no available means of comparing the speeds of different plates sold. A speed list was a necessity for my method, and the only way for me to get the information was to actually test all the plates. I soon found that makers had an inconvenient way of altering their speeds, and to cope with this the list has for some years been kept always in type, and corrections in speed made as soon as they are discovered. Had I been aware of the infinite labour involved in this work, I doubt if anything could have induced me to put my hand to the plough. The worst of it is that, when the result of a test makes it necessary to change the number put opposite a plate, I am sure to get a letter within a few days, asking how it is that I put Messrs. Mède & Persian's "Thunderbolt" at 100, whereas they used to be put at 120. Frankly, I can only regard such a list as a makeshift, to be superseded in time by a uniform plan of speed-marking each box. One rule I have always made, I have never yet quoted a speed number to a plate which was not the result of an actual test by myself; and, as fast as the makers adopt the H & D. plan of speed-marking each box, I am only too glad to cease quoting approximate values to their plates, and to give instead the ratio which their numbers bear to the numbers used in my exposure meter.

I am often asked the question, "What relation do the Warnerke numbers bear to the speed numbers for your meter?" I am obliged to refuse to quote any ratio, because these numbers do not appear to be the result of a test of each batch of plates but mere trade designations printed year after year in the circulars and on the boxes.

Practically the Hurter & Driffield system of speed-marking is the only one in the field at the present time in England. One firm, Messrs. Marion, commenced its use about 1890. Others have followed, at first cautiously and partially, but not one who has commenced to speed-mark each box has, so far, turned back.

Unfortunately it is necessary to point out that different makers' H. & D. numbers have not all the same value. If all used the same standard light, the same developer, at the same temperature, the expression H. & D. 100 would be an absolute one. But under present circumstances it

varies with different makers. There are four makers who speed-mark each box with H. & D. numbers; my own trials (testing altogether by the same method) show that to bring all to a uniform value one has to be multiplied by 2½, one by 1, and two by 1½. The term "H. & D. 100," printed in a circular or on the label of a box in such a way as to indicate that it is a stock number always on that box, is of no more definite value than the term "extra rapid."

It is of the greatest importance that the values indicated by speed numbers should bear the simple ratio indicated by the figures, so that a plate marked 100 will require half the exposure of one marked 50. In the Warnerke numbers each one is supposed to indicate a plate one-third more rapid than the number below, and it is always a puzzle to find out what relation Warnerke 25 bears to Warnerke 30. A still more perplexing plan is to designate the speed of plate by the ratio of diaphragm which will give a standard exposure with it, *f*-45, for instance, being double the speed of *f*-32. It is not difficult to recognise these ratios when the stops are familiar ones, but, when less-known ones, such as *f*-90 and *f*-110, are quoted, and, worse still, when these numbers are printed on a box with the *f* omitted, it would be difficult to add to the muddle.

An ideal plan of uniform speed-testing, but one, I am afraid, not likely to be adopted under present circumstances, would be for some authority, such as the Royal Photographic Society, to establish a central bureau for speed-testing. Makers joining would send samples of each batch made, and the bureau would issue labels bearing the speed, length of gradation, and density-giving value of the plate.

I cannot help wondering whether, when uniform speed numbers come into use, the speed anomalies which are now occasionally met with will cease. For instance, a firm (not an English one) issues three or four brands supposed to be from slow to extra rapid, and, on trial, the supposed highest speed was found to be identical with the lowest. It is more frequent than might be supposed for a maker's top brand to prove on testing to be practically the same as the next on the list, with perhaps a little fog thrown in for the extra price; and on two occasions, in testing the slow and rapid bromide papers of well-known makers, I have found them to be identical. It might be a mistake in packing, but the result to the user remains the same. These are exceptional cases, and, although the approximate ratio of speed given by makers to their different brands is seldom to be depended on, the order of speed is, as a rule, correct.

ALFRED WATKINS.

#### BLACKLEAD PENCILS.

A VERY interesting article appears in the *Chemical News* from the advance sheets of the *Journal of the Franklin Society*, treating upon the origin and manufacture of plumbago—blacklead. Without the so-called blacklead the business of a great many skilled workers would, for a while, be at a standstill, though it should be remembered that the earliest retouchers in this country did not make use of this material upon their negatives. Mr. Edge of Llandudno, of Preston also, in those days, we believe, depended entirely upon Indian ink blacklead pencils, not having any place in his *atelier*, and his work was of the smallest and most delicate. We are sorry to find that up to the present time "blackleads" "made in Germany" have had the preference in this country almost to the exclusion of home-made, though we believe that there are English-made pencils now on the market equal to any foreign. Time was when the market depended for its highest quality of leads entirely upon the output of the mines in Borrowdale, in Cumberland, their product being a beautifully even "lead" entirely free from grit. The pieces of blacklead were simply sawn up and placed in cedar. Nowadays the quarries are exhausted of all large pieces, and we do not believe it is possible to obtain a pure Cumberland lead pencil, whose length of lead is not made up of a number of pieces with a maximum length of an inch or an inch and a half. Some idea of the beautiful character of this material may be formed when we say that we have seen the retouching of a face done direct on to the collodion film without varnish or protection of any kind. At the present time the raw material is made into a fine powder to remove grit, and, with other ingredients added to it, formed into a compact mass by the application of great pressure.

In the article we refer to the writer describes a new process for actually making this graphite by electrical means, and, so far assured of success is the process, that a number of capitalists have combined to erect work: the Niagara Falls' Power Company's Land. The basis of the process is the breaking up of a carbide by the aid of electricity, and already there has been a large output of graphite articles, though of almost non-photographic interest; 200,000 carbon electrodes fifteen inches long and one inch cross section, for example, have already been made.

## SILVER SUB-BROMIDE, THE LATENT IMAGE, AND NASCENT SILVER.

(Translated from the *Photographische Correspondenz*.)

In the last number of the *Photographische Correspondenz* (1899, p. 276) \* I refuted the opinion that nitric acid had the power to destroy the latent image formed by the action of light, and I showed that the principal support of the nascent silver theory (*Silberkeimtheorie*) was thus removed. It is impossible that metallic silver can be formed primarily in the latent image as required by the nascent silver theory, which in my opinion is an erroneous one. It yet remains to be considered to what extent the immediate contact of silver bromide with metallic silver, formed by reduction in the process of development, assists as a concomitant, secondary process in strengthening the image during prolonged development. I referred to this in my last article.

I have made fresh experiments in order to ascertain the behaviour of unexposed silver bromide in contact with silver wire in presence of an oxalate of iron developer. In the series of experiments, which I made many years ago, I observed that reduction by contact took place at those points where contact existed, but a recent repetition of this experiment gave negative results, that is to say, no reduction took place when strong mechanical pressure was avoided. As I have repeated this fresh series of experiments without distinctly being able to detect any reduction of silver set up by the silver wire during the action of the developer upon unexposed silver bromide, I find the opinion, which I recently expressed, considerably strengthened, that the primary image impressed by light is attributable to the formation of sub-bromide by separation of bromine from the exposed silver bromide. The contact of metallic silver with silver bromide merely brings about a subsidiary, secondary effect which is often imperceptible. I attached undue importance to this in the past, but the adherents of the nascent silver theory have over-estimated it in much greater degree.

In accordance with the fundamental facts shown by these experiments, I maintain that the nascent silver theory is inadequate and inapplicable. The opinion that the latent photographic image is due to a change in molecular structure of the silver bromide has more in its favour. This, for instance, is held by Hurter & Driffeld, who try to prove that a complex molecule of silver bromide ( $\text{Ag}_m\text{Br}_n$ ) is changed by the action of light to a simple molecule.

According to the sub-haloid theory it is assumed that  $\text{Ag}_m\text{Br}_n$  is changed to  $\text{Ag}_m\text{Br}_2$  by loss of bromine,  $m$  being greater than  $n$ . By the latter theory the addition of bromine in the elementary state should destroy the latent photographic image and convert it to normal silver bromide, the bromine which was lost being restored to the molecule and forming silver bromide as it existed prior to exposure. I repeated the experiment, which has frequently been described, in the following manner: A collodio-bromide wet plate was prepared (see *Photographische Correspondenz*, 1899, p. 277)† and exposed in the camera. The silver nitrate was removed by washing, the plate then immersed for seven minutes in a one per cent. solution of potassium bromide and afterwards developed with an alkaline glycin developer. A plucky negative was obtained, as the alkaline bromides do not destroy the latent photographic image. In the next experiment bromine water was added to the solution of potassium bromide until it assumed a pronounced yellow colour. After bathing an exposed plate in this solution the developer did not produce any trace of a photographic image.

It is easy to show that this experiment harmonises with the silver sub-bromide theory, but it is difficult to make it agree with the opinion that the molecular structure of the latent image is changed.

It seems to me, for these reasons, that the sub-haloid theory of the latent photographic image agrees most readily with the facts ascertained by experiment, and at the same time it suffices to explain the photographic phenomena in an adequate and unstrained manner.

DR. J. M. EDER.

## FOREIGN NEWS AND NOTES.

**Cyanotype.**—Gustav Griot informs the editor of the *Photographische Correspondenz* that he has found a noticeable difference in the character and sensitiveness of cyanotype paper according to the length of time the sensitising solutions have been kept. The formula used was taken from Dr. Eder's *Ausführliches Handbuch* (second edition, 1899, vol. xiii.). Freshly prepared solutions of ammonium ferric citrate and ferricyanide of potassium, used half an hour after preparation, gave a paper showing perceptible grain and a tinge of

\* THE BRITISH JOURNAL OF PHOTOGRAPHY, 1899, p. 307.  
† Ibid, p. 308.

grey. The prints were hard and not suitable for half-tone subjects. After keeping the separate solutions for a day, the paper showed no grain and was of a pure yellow colour. This was also the case even when the solutions had been kept for weeks. The paper was likewise three times more sensitive and gave pure whites and good half-tones. The appearance of the prints made with solutions which had been kept was far superior and more delicate than of those made with fresh solutions. The same salts and paper were used in each case, and the prints were made immediately the paper was dry.

**A New Fixing Agent.**—In the current number of the *Bulletin de la Société Française*, Messrs. Lumière give particulars of a new fixing salt (acid anhydrous hyposulphite of soda), which they recommend. It dissolves immediately. Taken weight for weight, it does twice the work. Being acid, it does not become discoloured rapidly, even if the plates have been insufficiently washed before fixing. It also tends to harden the film of a gelatine negative. The salt should be used in an eight per cent. solution.

**Pope Leo XIII. and Photography.**—We read in *Ombres et Lumières* that the following Latin verse is from the pen of the venerable head of the Roman Catholic Church:—

"Ars photographica,  
Expressa Solis spiculis  
Nitens imago, quam bene  
Frontis decus, vim luminum  
Refers, et ovis gratiam!  
O mira virtus ingeni!  
Novumque monstrum! Imaginem  
Natura Apelles amulus  
Non pulchriorem pingeret."

**Copper versus Zinc for Process Work.**—The French paper, *Typo-Litho*, draws attention to the superiority of American process work, and points to the use of copper instead of zinc plates as the cause. One of the difficulties experienced in process work is that, after a number of impressions have been taken from a zinc plate, it blocks up. This was the difficulty experienced in America until the enamel process upon copper was used. If we examine with a strong magnifying glass the ground of a zinc plate etched with nitric acid, and compare it with that of a copper plate etched with perchloride of iron, the former will have a rough appearance, resembling a file, whilst the latter is clean and the points stand out from it in good relief. The condition of the zinc is such that the roller gradually fills up the interstices. Two hundred and fifty thousand impressions can be taken from a copper plate etched with perchloride of iron.

**Printing Unfixed Negatives.**—M. Ch. Gravier obtains a quick proof by washing the negative for a short time after development, pressing upon it a piece of bromide paper previously soaked in water and exposing it to a lamp for a few seconds. The exposure is, of course, much longer than would be required for a fixed negative, but the print is scarcely distinguishable from one obtained in the ordinary. The negative may afterwards be fixed in the usual manner. M. Gravier obtained a print in this way about two minutes after exposure, under specially arranged conditions. The following is the record of the operations: Development of the negative, 30 seconds; washing, 5 seconds; pressing on the soaked bromide paper and drying the back of the negative, 6 seconds; exposure of the print to gas, 5 seconds; development of the print, 30 seconds; fixing the print in a twenty-five per cent. acid fixing bath, 30 seconds; washing, 5 seconds.

## REPRODUCING AND ENLARGING NEGATIVES.

[Paper read before the Photographic Society of Philadelphia and reprinted from its *Journal*.]

THE process of reproducing negatives is one whose value has been underestimated or the difficulties exaggerated. It is needless to enumerate the various instances when it becomes desirable for the photographer, be he amateur or professional, to duplicate a negative. There are many of the former class who do not care to be encumbered with a large camera, but who, in the course of their travels, succeed in obtaining many artistic pictures, which, but for their size, would be well worthy of framing. It is always a satisfaction to the amateur photographer to point to sundry pictures adorning his wall, and exclaim with pardonable pride, "I made those!" By the process of reproduction it becomes possible for him to

obtain an enlarged copy of his original negative, from which most satisfactory contact prints may be made.

It frequently, too, happens that a photograph is made with a small camera, not from choice, but from necessity, as, for example, in photographing from a boat in motion. The negative thus made can be enlarged to the required size, with precisely the same result as if a larger camera had been used in the first place.

Sometimes a rare or valuable negative is made upon thin glass, and, although it is necessary to make a number of prints from it, the owner does not care to risk its possible injury. A duplicate of the original easily solves the difficulty.

Again, an order comes in for a great number of prints, and it is found impossible to make them in the allotted time from one negative, but by reproducing this negative the work is accomplished with facility.

A broken negative which cannot readily be replaced may be successfully reproduced.

I have, in fact, been called upon frequently to enlarge negatives where it was impossible or too expensive to make them over direct. A reversed negative is sometimes wanted of a choice subject for a photo-mechanical process.

Appreciating the value of the process, the first step is the making of the positive. No doubt, carbon is the most satisfactory, as there is no grain or deposit, but few can handle the process, and it is seldom used, excepting by some of the large firms, who have every facility at hand. Albumen is also most satisfactory, but the formula is complicated and tedious, and the once well-known "Edwards process" is now obsolete, or seldom used. Thoroughly satisfactory results can be obtained with commercial gelatine dry plates. Various writers have contended either for contact or enlarged positives. My experience has been in favour of a contact positive, unless the resulting negative was to be greatly enlarged and the positive needed considerable spotting or artistic hand work.

Having carefully studied the character of the negative—its unevenness, its colour—carefully clean the back, and place in a deep printing frame a size larger than the negative, having in it a thin plate glass free from bubbles and scratches. Arrange the negative in the centre, brushing away all grit or dust with a soft blender, and place the plate face down in contact with the negative, using a dark, soft pad between it and the back, which must be gently pressed into position.

A light of standard intensity should be adopted in order to ensure success in exposing, and it should be enclosed in a lantern with an exposing door.

A Welsbach jet is uncertain unless the mantles are frequently renewed. An ordinary gas jet or incandescent lamp of either sixteen or thirty-two candle power will answer, although a good oil lamp is probably as sure as any other light, and quite satisfactory.

The length of exposure will depend on the speed of the plate, the distance from the light, and the density of the negative. A negative of average density, with a rapid plate, requires from three to six seconds, when the exposure is made within eighteen inches from the light, and increases with the distance. During the exposure, dodging may be resorted to—such as shading thin places or prolonging the exposure in dense portions by moving in front of the subject a card with a hole, moving this so that no sharp outline may result.

I prefer using a plate a size larger than the negative in order to get a more even positive. Having properly exposed the plate, development is next in order. Any good developer will do, but I prefer one giving a grey image, similar to wet collodion. I have used, for several years, a formula worked out by Mr. William Bell, which is most satisfactory, and is as follows:—

## No. 1.

Water ..... 64 ounces.  
Sulphite of soda crystals ..... 4 "

Dissolve, and make slightly acid with sulphuric C.P., then add—

Eikonogen ..... 320 grains.  
Hydroquinone ..... 320 "

## No. 2.

Water ..... 64 ounces.  
Sulphite of soda crystals ..... 2 "  
Carbonate of potash ..... 8 "

To dissolve the sulphite of soda crystals in No. 1 solution, heat about one-third of the water, and the soda will dissolve more readily. To develop, use equal parts of No. 1 and No. 2.

In warm weather, reduce with one-third water. Bromide is a very active restrainer, and should be used cautiously. Should a positive be desired requiring brilliancy, use less of No. 2 and more of No. 1, and *vice versa*.

Develop slowly and carefully, and try for a positive that will have the highest lights fully covered, and the shadows soft and full of detail. Should it be the intention to enlarge the negative, then make the positive somewhat weaker than for contact. I believe most failures are due to poor positives, and I will show two that I used to enlarge from that are just right. A positive cannot safely be judged by artificial light, as colour will show only in daylight.

Should the negative to be reproduced be broken, carefully lay the

pieces together, bringing them in close contact, and, if possible, hold the printing frame during exposure in such position that the cracks will cast no shadow; if this is not possible, move the frame slowly during exposure, to lessen the shadow of the break. The positive should then be placed in the hands of a skilled etcher and retoucher, who can scrape away and fill in with ink, until the mark is lost. In fact, a great amount of careful retouching can often be done on the positive.

The making of the negative is done in precisely the same manner as making the positive, when a negative of the same size is desired.

Should the reproduction be wanted for phototyping or any process requiring a reversed negative, the negative must be made in the camera, placing the positive in position with the film turned away from the lens. In enlarging negatives, either a lens of short focus or a camera having a long bellows should be used. Any good lens will do, although I prefer one that is rapid and rectilinear. The time of exposure depends on conditions of light, colour of the positive, and speed of the plate used. In this part of the process I generally use rapid plates, and develop precisely as though the exposure was a portrait or landscape, watching for the same effect, and in every way judging the result of the same.

Cleanliness, good judgment and care, with skill in development, are necessary to obtain the best results.

W. H. RAU.

## NEW METRIC WEIGHTS AND MEASURES.

(From the *Journal* of the Royal Photographic Society.)

In accordance with a resolution passed by the Council of this Society, directing the publication, in the *Journal*, of the Order in Council dated May 19, 1898, substituting a new table of imperial and metric equivalents for that set forth in Part I of the Third Schedule of the Weights and Measures Act, 1878, we give below an abstract from the new Schedule of such measures of weight, length, capacity, &c., which are in common use amongst photographers in this country:—

## Equivalents of Metric Weights and Measures in Terms of Imperial Weights and Measures.

## LINEAR MEASURE.

1 millimetre (mm.) ( $\frac{1}{1000}$ m.)	...	=	0.03937 inch.
1 centimetre ( $\frac{1}{100}$ m.)	...	=	0.3937 "
1 decimetre ( $\frac{1}{10}$ m.)	...	=	3.937 inches.
1 metre (m.)	...	=	39.370113 inches.
			3.280843 feet.
			1.0936143 yard.
1 decametre (10 m.)	...	=	10.936 yards.
1 hectometre (100 m.)	...	=	109.36 "
1 kilometre (1000 m.)	...	=	0.62137 mile.

## SQUARE MEASURE.

1 square centimetre	...	=	0.15500 sq. inch
1 square decimetre (100 square centimetres)	...	=	15.500 inches
1 square metre (100 square decimetres)	...	=	10.7639 square feet.
		=	1.1960 " yard.

## CUBIC MEASURE.

1 cubic centimetre	...	=	0.0610 cubic inches.
1 cubic decimetre (c. d.) (1000 cubic centimetres)	...	=	61.024 "
1 cubic metre (1000 cubic decimetres)	...	=	35.3148 cubic feet.
		=	1.307954 " yard.

## MEASURE OF CAPACITY.

1 centilitre ( $\frac{1}{100}$ litre)	...	=	0.070 gill.
1 decilitre ( $\frac{1}{10}$ litre)	...	=	0.176 pint.
1 litre	...	=	1.75980 pint.
1 dekalitre (10 litres)	...	=	2.200 gallons.

## WEIGHT.

			<i>Avoirdupois.</i>
1 milligramme ( $\frac{1}{1000}$ gm.)	...	=	0.015 grain.
1 centigramme ( $\frac{1}{100}$ gm.)	...	=	0.154 "
1 decigramme ( $\frac{1}{10}$ gm.)	...	=	1.543 "
1 gramme (1 gm.)	...	=	15.432 grains.
1 dekagramme (10 gm.)	...	=	5.644 drachms.
1 hectogramme (100 gm.)	...	=	3.527 ounces.
1 kilogramme (1000 gm.)	...	=	2.2046223 lbs. or 15432.3564 grains.
1 quintal (100 kilog.)	...	=	1.968 cwt.

*Apothecaries'.*

1 gramme (1 gm.)	...	=	0.2572 drachm.
		=	0.7716 scruple.
		=	15.432 grains.

*Troy.*

1 gramme (1 gm.)	...	=	0.03215 ounce.
------------------	-----	---	----------------

*Equivalents of Imperial Weights and Measures in Terms of Metric Weights and Measures.*

LINEAR MEASURE.

1 inch	...	...	=	25.400 millimetres.
1 foot	...	...	=	0.30480 metre.
1 yard	...	...	=	0.914399 "
1 mile	...	...	=	1.6093 kilometre.

SQUARE MEASURE.

1 square inch	...	...	=	6.4516 square centimetres.
1 " foot	...	...	=	9.2903 " decimetres.
1 " yard	...	...	=	0.836126 " metre.
1 " mile	...	...	=	259.00 hectares.

CUBIC MEASURE.

1 cubic inch	...	...	=	16.387 cubic centimetres.
1 " foot	...	...	=	0.28317 cubic metre.
1 " yard	...	...	=	0.764553 "

MEASURES OF CAPACITY.

1 pint	...	...	=	0.568 litre.
1 quart	...	...	=	1.136 "
1 gallon	...	...	=	4.5459681 litres.

APOTHECARIES' MEASURE.

1 minim	...	...	=	0.059 millilitre.
1 fluid scruple	...	...	=	1.184 "
1 " drachm (60 minims)	...	...	=	3.552 millilitres.
1 " ounce (8 drachms)	...	...	=	2.84128 centilitres.
1 pint	...	...	=	0.568 litre.

AVOIRDUPOIS WEIGHT.

1 grain	...	...	=	0.0648 gramme.
1 ounce	...	...	=	28.350 grammes.
1 pound	...	...	=	0.45359243 kilogramme.
1 hundredweight	...	...	=	50.80 kilogrammes.

APOTHECARIES' WEIGHT.

1 grain	...	...	=	0.0648 gramme.
1 scruple (20 grains)	...	...	=	1.296 "
1 drachm (3 scruples)	...	...	=	3.888 grammes.
1 ounce (8 drachms)	...	...	=	31.1035 "

*Note.*—The metre is represented by the distance marked by two fine lines on the iridio-platinum standard bar numbered 16, when at the temperature of 0° Centigrade. This bar is deposited with the Board of Trade. The metre is the only unit of metric measure of extension from which all other metric measures of extension, whether linear, superficial, or solid, shall be ascertained.

The kilogramme is represented by the cylindrical iridio-platinum standard kilogramme weight numbered 18, which is deposited with the Board of Trade. The kilogramme is the only unit of metric weight from which all other metric weights, and all measures having reference to metric weight, shall be ascertained.

The litre is represented by the capacity at 0° Centigrade of the cylindrical brass measure marked "litre, 1897" (which is deposited with the Board of Trade), and having a diameter equal to one-half its height. This litre at 0° Centigrade when full contains one kilogramme of distilled water at the temperature of 4° centigrade, under an atmospheric pressure equal to that represented by a column of mercury 760 millimetres high at 0° Centigrade at sea level, and at latitude 45°, the weighing being made in air, but reduced by calculation to a vacuum. It is the only unit of metric measure of capacity from which all other metric measures of capacity, as well for liquids as for dry goods, shall be ascertained.

RELIEF PHOTOGRAPHY: NEUHAUS'S PROCESS.

HERE NEUHAUS'S method, as described by himself in his Patent specification, is as follows:—

The photographic print which is desired to be put in relief should be mounted on some sized drawing paper (Dutch hand-made paper is to be preferred) by the aid of some strong glue. When the glue is dry, the outline of the image or parts of the image to be put in relief is traced upon the rear side of the mounted photograph by aid of holding the front side of said photograph towards the light, so as to allow the manipulator to look through the photograph. A retouching desk is the best thing to use for the operation.

The photograph is then damped with water on its front side within and along the outline of the portrait or parts of the portrait to be put in relief.

The photograph is then placed face downwards upon a piece of plastic material, as, for instance, pastaline (a kind of clay used by sculptors for modelling purposes).

The pastaline has first been furnished with a smooth surface of a suitable size by working it with a smooth roller.

In order to protect the photograph from direct contact with the generally somewhat sticky material upon which it is placed, the latter is covered with a piece of strong soft paper, for instance, paper treated with paraffin.

Those parts of the photograph which it is desired should be put in relief are now, from the back, with a suitable tool pressed or moulded downwards into the pastaline to such an extent as the face, figure, and costume to be put in relief may require and in accordance with the artistic taste of the manipulator.

The parts of the photograph once put in relief remain so by reason of the presence of the glue in the sized drawing-paper and between the print and the Dutch paper.

The picture may during the time it is worked be taken up and turned over in order to allow the manipulator to ascertain the effect; but, if further pressing or moulding has to be made, it must be kept constantly moist, as it would otherwise crack.

When the image has been made to stand out in the desired manner, it is dried, and the recesses at the back of it are filled with a little cotton-wool, whereupon it is placed, face upwards, upon a piece of the above-mentioned pastaline, which has been furnished with a smooth surface.

The photograph is then covered with a piece of strong, soft, transparent paper, as, for instance, paper treated with paraffin.

The outline is now pressed or moulded with a suitable tool downwards upon the pastaline in places where parts of the figure to be placed in relief are desired to be brought sharply out, the paraffin paper preventing any damage to the print.

Finally, the photograph is taken into the hand and the finishing moulding of the image is made with a suitable tool direct on the print without use of any paper between the tool and the print, the finger being used for backing support.

The photograph worked out in relief is now mounted on the same sort of sized paper as used for mounting the print.

A piece of said paper of same size as the photograph is covered with a coat of glue, and the photograph, in dry condition, is then placed upon it without filling in of anything between the paper and the recess in the photograph. The photograph is then pressed by the aid of the hand downwards against the paper, but only at those parts of the photograph that have not been brought to stand out in relief.

The object of placing the dry photograph on the paper, that has been made wet by the glue, is to allow the paper to help to keep the relief photograph in the form it has received by the aid of shrinking as it gets dry.

The mounted photograph is now ready for framing.

TRICHROMATIC PHOTOGRAPHY AT THE ROYAL SOCIETY'S SOIREE.

ONE of the most interesting exhibits, from a photographic point of view, at the recent Ladies' Night of the Royal Society was that of Mr. W. Saville-Kent, F.L.S., which included some excellent examples of lantern and stereoscopic slides as natural-colour photographs. These transparencies were reproduced by the Ives system, the negatives being taken through screens of red, green, and blue-violet, and positives produced as three-film or glass transparencies from same, each of which is tinted with the colour complementary to that of its respective negative, and then the three are superimposed in correct register.

The excellence of the later examples produced is such as to justify reference to the subjects themselves, and certainly, for a naturalist or biologist, the system was shown to be of special value, as permanent records of colour are by its means obtained even of marine and other forms of life that have brilliant tints of an evanescent character.

On the table and in a show frame were transparencies of a larger size that were exhibited at the previous (black) *Soirée* of the Royal Society, and one particularly, of half-plate size, gave a faithful representation of the Queensland regent bird and laughing kingfisher. Here the colours were very pure, and among some of them noted were lilac, blue (deep and light), yellow, and brown and grey in the bird's tail. A stuffed specimen of one of the birds represented in the photograph was on the table for comparison, and certainly the purpose was well served, for the transparencies were very like the original. A blue morpho-butterfly was also well reproduced, while Brazilian foliage looked very natural, and pale pink cacti showed most delicate of tints. It is to be hoped that Mr. Saville-Kent will give a demonstration of his method of working, or read a paper shortly on the subject, so that other workers who have time to do so may take up this interesting branch. The results are, no doubt, largely due to manipulative skill and care, for the superposition in the subject we have referred to was excellent, and even stood the test of a critical examination with a magnifier.

It was understood the exposure when making the negatives was about ten minutes altogether, the red requiring five; green, three and a half; and blue, one and a half minutes. Of course, with these long exposures, only still life can be reproduced, but Mr. Saville-Kent is personally so-

impressed with the value of the process that he proposes visiting Australia again, and using this method of obtaining records for the illustrations in his new books on zoological and botanical subjects. Asked as to the cost of production of such transparencies, he said that, from his experience and the time taken by himself, he should say they could, as a commercial matter, be sold as lantern slides at five shillings each, and as half-plate transparencies at one guinea each.

### "COUNTRY LIFE" PHOTOGRAPHIC COMPETITION.

Our contemporary, *Country Life*, is organizing a photographic competition, of which, in its last issue, it gave the following particulars:—

From time to time readers of *Country Life* who are interested in photography send specimens of their work. Many of the photographs they forward are of excellent merit. With a view to their encouragement it has been determined to begin another photographic competition. A first prize of twenty pounds, second prize of ten pounds, and third prize of five pounds will be given for the three best sets of not less than twelve photographs illustrative of country life in any of its phases. The following list will suggest the subjects that will receive favourable consideration:—

Gardens such as those appearing with the articles "Gardens Old and New," cottage gardens, tree and floral studies, moated houses, old wrought-iron gates and other ironwork, picturesque villages and cottages, village industries and life, village halls, agriculture in any of its forms, picturesque farm buildings, leadwork—vases, figures, cisterns, &c., animal or bird life, doves, various outdoor sports, such as fishing, shooting, hawking, yachting, &c.

In addition to the three prizes named, a special one of five pounds will be given for the best set of not less than six photographs illustrating the most artistic effects that can be obtained in gardening.

The photographs should be silver prints—preferably on printing-out paper—not smaller than half-plate size, and should be carefully packed, and addressed to the editor in a parcel bearing the words "Photographic Competition" on the outside. For the purpose of identification each individual photograph must be clearly marked with the name and address of the competitor, but no responsibility for the safe keeping of the competing photographs can be accepted, although every care will be taken to return safely any unsuccessful photographs if stamps for this purpose are enclosed.

It is understood that all reproduction rights of the successful photographs will pass to the proprietors of *Country Life*, and, if required, the negatives of these pictures will be given up to them. The proprietors also reserve to themselves the right to make use of any of the unsuccessful photographs upon payment of from 5s. to 10s. 6d. for each picture published, according to their idea of merit.

The competition will close on October 14, and the decision of the editor, which will be final and without appeal, will be announced as early as possible after this date.

### A NEW PRINTING PROCESS.

It is a somewhat bold statement to make, but it looks, says the *Scotsman*, as if the printing trade were on the eve of a far-reaching change. For some time inventors have been at work trying with but scant success to utilise electricity so as to do away with the necessity of using ink and rollers, and both in America and in France reliance has been placed on the Röntgen rays, a process which, so far as it has gone, would be of little practical value, owing to its cost and the development necessary to give prominence to the text or illustrations fixed on sensitised paper, a process occupying so much time as to render it useless where quick work is essential, as in connexion with the issue of newspapers.

While many inventors have been trying to abolish types, machines, ink, and the printer, Mr. W. Friese-Greene turned his attention in another direction. Without abolishing the use of type he has succeeded, by means of electricity and paper chemically prepared in the course of manufacture, in getting a clear and readable impression in dense black or in any lighter colour through electrical resistance applied to the printing surface, whether type or stereotype, without the use of ink or rollers. Everybody familiar with the printing trade knows what a boon it would be to be able to do away with ink, which is not only a necessary but a costly item in the production of printed work.

It is asserted by those into whose hands Mr. Greene's patent has passed that the chemical process of sensitising the paper at the time of manufacture is so easy and so cheap that it will not make the slightest difference in the selling price of paper. The new chemical will take the place of one now used in paper-manufacture, and licences at a merely nominal charge will be granted to any paper-maker, so that, if the new process of printing becomes common, supplies of paper will be obtained through existing channels.

One exceedingly important feature in the new invention is that there will be no necessity for those already possessed of printing plant to dispense with the old and replace it with new machinery. All that is necessary is to leave off the rollers and discard all the movable parts of the working arrangements that do not interfere with the running of the machine, and to cover the cylinder with a thin sheet of zinc. It is then

ready to be put in circuit with the electric current in the usual way by means of negative and positive wires, which come in contact with every revolution of the cylinder, and produce the printed sheets in the case of fast rotary news machines at a rate that is claimed to be equal to three to two as compared with the speed of existing machines using ink and rollers.

It is claimed for the invention that it will largely reduce the cost of printing, that it is much clearer, and that the impression produced is superior to that obtained by any existing ink process. Practical demonstrations of the work can be seen at the syndicate's headquarters in London on ordinary printing machines, with all the unnecessary portions removed, and arrangements are rapidly being completed to offer the invention to the trade. It may be interesting to mention that the syndicate which has possession of the patent is composed exclusively of Scotsmen, and a good deal of money for experimental purposes has been found in Edinburgh. So far the printing trade has been very sceptical as to the value of the invention.

### TRICOLOUR TRANSPARENCIES FOR PROJECTION AND THE STEREOSCOPE.

I.

The following notes in the current number of the *Photographische Rundschau* on the above subject, by A. Freiherr von Hübl, the well-known writer and author of the book, *Die Dreifarben-Photographie*, may be of interest at the present moment, when so much attention is directed to this subject.

When two or more colours are mixed together, there is formed, besides the new colour, always a certain quantity of black, which gives the compound colour an impure appearance. Precisely the same phenomenon occurs when coloured light is added to coloured light, only in this case the impurity is the admixture of white. For instance, if a yellow and blue pigment be mixed together, the result is not a pure, but only a dirty green, and, if yellow and blue light be mixed together, a greenish white is formed.

The impurity by black or white is the more noticeable the more impure the colours used for making the mixture are, since the intensity of the sensation increases in logarithmic progression with the quantity of the black or white that is present. The quantity of the black or white formed is greater the further the components are separated in the chromatic circle; that is to say, the more different they appear to our eyes. Peacock blue and yellow give a relatively pure green; with Paris blue and chrome yellow there is formed a muddy green; ultramarine and chrome yellow give only a greenish grey; and with suitable colours there disappears, as is well known, any sensation of colour, and only pure grey or black is formed.

These facts are of great importance for the indirect production of colours. If with this process correct and sufficiently bright mixed colours are required, there must be used not only the correct, but, as far as possible, the purest fundamental colours.

For three-colour printing this requirement of the purity of the colours cannot be absolutely fulfilled, and, even if the photographic separation of the colours is perfect, one has always to contend with the degradation of the mixed tones. This is principally the case with the green, which, without retouching the red plate, almost always appears impure, since, for the formation of this compound colour, almost all the printing inks usually chosen are unsuitable. In polychrome projection, and in Joly's line process, yellow, bluish-green, and carmine appear insufficiently saturated and almost white.

These colours behave most favourably in transparent pictures prepared according to the three-colour printing process. The separate monochrome pictures required for this work can be prepared so pure in colour by means of aniline colours that the compound colours formed by superposition show absolute brilliancy. This process gives therefore undoubtedly the most perfect results, and surpasses, as regards the correctness of the colour reproduction, any other method of indirect photochromy. Without any retouching of the negative all colours are obtained, and not one appears to be printed at the cost of another, and therefore this process forms a striking proof for the possibility of three-colour printing, and for the correctness of its theoretical basis.

Such transparent images are especially suitable for projection work, and recently Lumière has placed such stereoscopic pictures on the market under the name of "Photographie des Couleurs." With the latter there is formed, not only the colour brilliancy of the object true to nature and the reproduction of the bloom, but stereoscopic relief, so that an astonishing effect is obtained.

The author has already, in 1897,\* described the method of preparation of such three-colour pictures; but, as since that time improvements have been effected, a connected description of this process is given in the following lines, especially with regard to the preparation of lantern and stereoscopic pictures:—

First of all, the fundamental colours for the monochrome pictures have to be chosen, then the three negatives have to be prepared to correspond to this choice; from these transparent prints in these colours have to be produced, and, finally, these have to be combined, by superposition, to form the finished picture.

\* *Die Dreifarben-Photographie*, 1897

As fundamental colours, crimson, greenish-blue, and yellow are chosen, a colour system the theoretical correctness of which the author has repeatedly proved.

#### I.—THE PHOTOGRAPHIC NEGATIVES.

(a) *On the Colour-sensitive Plates.*—On the ground of reasons to be explained hereafter, the use of the gelatine plates will be found to be the most convenient, and they must be sensitised for the above fundamental colours.

For the negative which is used for the preparation of the yellow print an ordinary plate, without a light filter, may be used. Theoretically, the use of a violet filter is correct, in order to reduce the action of the blue-green rays. Its action is, however, scarcely recognisable, and there in practice this complication may be avoided.

The gelatine plate which must give the negative for the red print must be sensitive to yellow and green. On account of simplicity it is advisable to use a commercial orthochromatic plate, although its band of sensitiveness only incompletely satisfies the theoretical requirements. By means of a tolerably deep green filter, the natural blue sensitiveness of the plate is eliminated, and the sensitive band corrected by displacement towards the blue-green.

The third negative (for the blue print) requires the use of a red and yellow sensitive plate and an orange filter. A Lumière orthochromatic plate, Series B, or a cyanine-bathed plate may be used, for the preparation of the latter has suggested a process which has proved to be excellent. The sensitising bath is composed of—

Dextrine solution (ten per cent. in water) .....	400 parts.
Alcohol .....	150 "
Cold saturated solution of borax .....	20 "
Cyanine solution (1:500) .....	3 "

Ordinary, clear, and vigorous working plates are immersed in this solution for about five minutes and then dried in absolute darkness away from dust. The solution will keep for a long time, but must be filtered each time before use, and enough cyanine added so that it appears a bright blue.

The plates will keep for about eight days. They are extraordinarily red sensitive, and require a shorter exposure than the above-mentioned Lumière plates. On account of this high sensitiveness they must be in all manipulations, especially in developing, most carefully protected from red light.

If to the above sensitiser about 8 parts of a 1:50 solution of acridine be added, and, instead of the ordinary, a commercial orthochromatic plate be bathed, the result will be a plate which may also be used for the red printing. They are then panchromatic, and may be used for all three exposures, and only the filters have to be changed. The difficulty in handling cyanine bath plates makes this recommendation, however, less worthy of recommendation.

(b) *The Colour Filters.*—For the colour filters the best thing to use is thin glass plates of the exact size of the dry plate, coated with coloured gelatine, which should be placed with the coloured film in contact with the film of the plate in the dark slide. If these filter plates are chosen of equal thickness, the sensitive plate will always be at the same distance behind the optical image, and therefore the negative would be out of focus, and consequently it is advisable to focus with the ground glass reversed in the frame or to focus as usual, and then to displace the lens or the dark-slide frame the thickness of the filter plate.

The exposure for the yellow plate is effected, as already mentioned, without a colour filter, and therefore a piece of plain glass should be used instead of this. The placing of the filter in the dark slide is in such small sizes as would be used for lantern and stereoscopic work to be preferred to any other system, for in this way absolute sharpness of the negatives is obtained, and there is no necessity to change the filters, and, if three dark slides are used, the exposures may be made one after the other without loss of time.

The plates for the coloured filters are obtained by bathing a sheet of glass-coated with gelatine in the proper dyes, and the simplest way is to employ unused gelatino-bromide plates, to treat them with hypo, in order to dissolve the silver bromide, and then to thoroughly wash. Plates should be chosen of equal thickness, without flaws in the glass, and of which the silver-bromide film is equally thick, and not damaged, and which show neither streaks nor other coating failures. After washing, the plates, whilst still wet, are placed in a dish and flowed over with the dye solution, and left till the gelatine film appears sufficiently saturated with colour, for which some hours are required. In order to prevent unequal absorption of the dye, the dish should be occasionally shaken. The following is the composition of the dye baths recommended:—

#### For the Orange Screen.

Water .....	100 parts.
Alcohol .....	20 "
Biebrich scarlet (1:200) .....	20 "
Methyl orange (1:200) .....	5 "
Naphthol yellow S.L.* (1:200) .....	5 "
Glacial acetic acid .....	3 "

\* To be obtained from the Aktiengesellschaft für Chemische, Basle.

#### For the Green Screen.

Water .....	100 parts.
Alcohol .....	40 "
Echtgrün blaulich* (1:200) .....	12 "
Naphthol yellow S.L. (1:200) .....	40 "
Glacial acetic acid .....	3 "

When the plates have become a deep colour, they should be washed in distilled water mixed with a little acetic acid, and then deposited in a place free from dust to dry. Whether the intensity of the colour is sufficient can only be determined by experiments with a colour chart, and the author specially recommends that issued with his previously mentioned work.

(c) *The Process of Making the Negatives.*—In three-colour photography, all failures in the three positives will be seen as failures in the reproduction of the colours, and these will be principally seen in the compound colours which are formed by the admixture of the fundamental colours. This applies, in the first place, to grey, for the purity of which our eye is extremely sensitive; then, however, for all broken tones, such as brown, chamois, &c.

The reproduction of objects with vivid colours is, therefore, the easiest, whilst objects poor in colour can only be rendered true to nature by faultless harmony of the three positives.

For these reasons it is easy to make colour pictures of flowers and fruit, whilst landscapes and portraits present considerable difficulties. The neutral shading of silver objects appears with the least error untrue, whilst gold, brass, and copper always reproduce well.

Extensive surfaces of uniform colour lose, by almost invisible faults in the positive, their even colouration, and appear then unequal in colour, which detracts in a high degree from the impression of the whole picture.

These difficulties should be kept in mind when choosing and arranging the objects to be reproduced. A smooth grey or bright brown background, for instance, should always be avoided, a black or white one is always satisfactory; velvet or plush drapery in lively red, blue or green colours, are specially to be recommended for stereoscopic work, as the brilliant gloss and the texture of such materials are readily reproduced. For lantern slides, on the other hand, a coloured cloth or tapestry background is to be preferred.

The camera must be so fixed that any shift of the same when changing the plates is avoided. A very slight shift of the camera during the taking of the three negatives would alter the dimensions of the negative, and would exclude the correct superposition of the separate images. In stereo work special attention should be directed to the equality of the lenses and the diaphragms.

Outside the frame of the picture to be taken there should be placed a colour chart—the above-mentioned chart for instance—which not only serves for the control of the colour analysis but also prevents a later change of the negatives. These are generally so similar to one another that they can only be differentiated by very careful examination, whilst the colour chart appears very different and characteristic in each negative.

With solid objects the three negatives must be made as quickly as possible one after the other, not only because many objects, such as living flowers, are in continuous movement, but also because the ratio of light will alter, and then the gradations of the negatives will not be the same, and this may produce a marked alteration in the reproduction of the colours. This disadvantage, as well as the arrangement of filters above mentioned, induces one to use dry plates.

The plates for the exposures should be laid on the three dark slides, and each covered with its proper filter plate, film to film. As has already been mentioned, there should be used:—

1. An ordinary gelatine plate, covered with a colourless glass plate
2. An orthochromatic plate covered with a green filter; and
3. A cyanine bath plate covered with the orange filter.

As regards times of exposure the following data may be useful as a guide: For stereoscopic work in a studio the first plate should have three seconds, the second eight seconds, and the third fifteen seconds' exposure. The requisite ratio of exposure is, therefore, as 1:3:5.

There is, therefore, no difficulty of making the exposures all within one minute, and this time may, even in favourable circumstances, be reduced to half a minute. The potash-glycin developer with the addition of acid sulphite lye is the best to use.

Of special importance is the equal character of the negatives. In order to satisfy this requirement, it is advisable to place side by side with the colour chart three pieces of grey paper of different intensities, and to so expose and develop that this scale appears of equal density.

In no case ought fully exposed negatives to be tried, for then, if, for instance, the object contains much yellow, the negative for the yellow print will with correct exposure give the impression of an under-exposed plate, and it would be quite false to expose excessively long in order to obtain a well-worked-through negative. The absolute correctness of the negatives can only be estimated from the reproduction of the colour chart and the grey scale. If these are correctly represented, the principal object will also be right, and without these aids an estimation of the negatives as regards colour analysis and time of exposure is quite impossible.

## METALLIC PHOTOGRAPHS.

It is about two years since we referred to the charming method of photographic printing which the Metallic Photo printing Syndicate, of New Southgate, was formed to work and exploit. The results could not fail to excite admiration. The image, in brilliant pulverulent silver or gold, is transferred to a surface of polished mahogany, previously made black, and is subsequently treated and varnished in such a manner that the destructive agency of the most powerful acids has no effect on the picture, which may therefore be looked upon as possessing the elements of permanency in the highest degree.

The process since its first introduction has been considerably improved in its working details by Mr. F. Ahrlé, the managing director of the Company, and the latest specimens shown us possess a depth and richness of image which could scarcely be improved upon. Besides portraits, the process is well adapted for the reproduction of pictures, advertising plaques (sheets of ferrotype here constituting the support), and other purposes. Mr. Ahrlé tells us that, given suitable negatives, the best possible results are easily and inexpensively produced at his works.

Nothing could have a richer decorative effect in the house than a large portrait or reproduction of a picture with the image in bright silver or gold on a massive, highly polished ebony black support. Besides the element of permanence, these pictures have every good photographic quality, detail and gradation, light and shadow being perfectly rendered. We understand that these metallic photographs (in which the only fault we can find is their awkward name) are shortly to be brought very prominently to the notice of the public. We wish the process the very great commercial success it deserves.

## THE ENERGY OF RÖNTGEN RAYS.

SINCE the marvellous properties of the Röntgen rays were discovered very many experiments have been made to bear upon their application to physiology and surgery, says Dr. J. G. McPherson, F.R.S.E., in *Knowledge* for July. Dr. Poland's atlas of the development of the formation of the bones of the wrist from birth till seventeen years of age is one of the most startling of the recent successes of the process; and this has overturned to some extent the old theory of the formation of these bones.

There has been, however, as yet but little done to determine the energy of these rays. The Rev. Alexander Moffat, B.Sc., has been studying the subject in Erlangen, and has submitted to the Royal Society of Edinburgh the result of his investigations.

A. Rottl was the first to attempt to determine the duration of the Röntgen rays. He used a Ruhmkorff coil with a rotating interrupter to make and break the current in the primary circuit. On the interrupter he mounted a photographic plate, and in front of it had a screen of lead with a slit in it. The Röntgen rays were made to pass through the slit and make a photograph of it on the plate. From the amount of broadening of the photograph he found that the duration of a discharge was about  $\frac{1}{1000}$  second.

Dr. Trouton, of Liverpool, adopted the method of rotating a zinc-toothed wheel between the Röntgen lamp and photographic plate. A photo of the moving teeth was secured by making one interruption of the primary current in the induction coil, thereby letting one discharge pass. The duration of the radiation was determined by the departure from sharpness of outline of the photo; and he concluded that the duration of a discharge was from  $\frac{1}{500}$  to  $\frac{1}{1000}$  second. M. Colandeanu, adopting the same method, found the result to be about  $\frac{1}{1000}$  second.

M. Morize adopted Rottl's principle. He fixed the plate to one end of the axle of an electrometer, and at the other end he placed a toothed wheel which interrupts an electric current, and makes a contact which registers itself on a chronograph band. From the broadening of the image of the slit he found the duration of the discharge to be a little over  $\frac{1}{1000}$  second.

Mr. Moffat has now determined that this figure is far too low; in fact, he proves that the real duration is about a tenth part of that determined by Colandeanu and Morize. He used an optical bank, with a screen of barium platino-cyanide and the Röntgen lamp at one end, an amylacetate lamp, as a source of light, being at the other end to note the standard of comparison; between these was a movable photometer. In order to obtain as strong Röntgen rays as possible, he introduced an air spark into the circuit, thereby driving away the particles of dust in the air and making the discharge more sudden. The Röntgen lamp and the spark-interrupter were enclosed in a box, the lamp being fixed near one side. At the place where the rays from the anti-cathode were to be transmitted a small hole was bored and covered with thin black paper. On the other side of this paper the screen was fastened. In front of the screen was fixed a piece of cardboard with a small hole in it, and through this the light-emitting surface of the screen appeared.

The light from the test lamp had to be weakened, because the light proceeding from the screen was very faint. This was done by putting the lamp inside a wooden box. A hole was made in front of the box, and covered with translucent paper. In front of this was placed a piece of green glass. For a photometer he used simply two mirrors set at right angles to one another; in this way very little of the light was lost. To determine the quantity of light emitted by the translucent paper,

from the amyl-acetate lamp, he put at one end of the optical bank a lamp, and at the other end the box with the translucent paper thus illuminated. He found that the light emitted by the paper was one-twentieth of that of the lamp.

He then removed the translucent paper, and determined the extinction coefficient of the green glass by measuring the intensity of the light transmitted by them in comparison with that of the lamp alone. He found that the intensity of the light coming from the translucent paper, when weakened by transmission through the green glass, was about  $\frac{1}{10000}$  lamp.

Now, the light of the lamp is emitted during the whole time it is burning, but the Röntgen rays only during very short intervals of time. To determine the upper limit to the duration of these intervals, Mr. Moffat put in front of the screen an opaque screen with a small vertical slit, and examined the image of the slit in a rotating mirror. The slit was three millimetres broad, and the mirror was exactly opposite it at a distance of 27.5 cm., revolving at the rate of about ten revolutions per second. Now, he saw that the image was broadened one-tenth part; accordingly, the duration of a discharge must have been about  $\frac{1}{2} \times \frac{1}{10} \times \frac{1}{10} \times \frac{1}{10} \times \frac{1}{10} = \frac{1}{10000}$  second.

By a series of successful experiments Mr. Moffat has averaged the duration of a discharge of the Röntgen rays at  $\frac{1}{10000}$  second. This, at least, is the upper limit.

## A NEW DEVELOPING AND CHANGING TENT.

M. DONNY, of Paris, has devised an apparatus of this kind in two parts, the one a base part, A, and the other a vertical part, A', which, when the apparatus is not in use, may be caused to be secured one to the other for convenient carriage by latches, a. The vertical part, A', is hinged to the base part, A, so as to be capable of being uplifted into a vertical position perpendicular thereto, the vertical part, A, being secured in that position by means of struts, c, laterally placed.

The parts of the apparatus are connected together by means of a light-proof covering, d, such as American cloth, velvet, or the like, which,

when the vertical part of the apparatus is uplifted into its vertical position, is stretched out so as to form triangular flexible sides and an inclined upper surface. Upon this upper surface a piece of glass, n, coloured, so as to be proof to actinic rays, is fixed, while upon the under side of this inclined surface a screen, z, is provided to slide or to be adjusted into any position so as to entirely cover the under face of the glass or partially cover it by manipulation from within the apparatus. Upon the upper

edge of the vertical part an ocular glass or plate, *c*, is provided, through which the interior of the apparatus may be viewed, while immediately beneath, a door, *d*, is provided to permit of the introduction of the frames, baths, and plates to be used. Upon each side of this door, apertures, *e*, are formed for the introduction of the fore arms, these apertures having connected thereto sleeves, *e'*, which are caused to encircle the arms of the operator, so as to preclude the passage of light while permitting of the fore arms being moved within the apparatus for the manipulation of the frames and plates therein.

A cover or cloth, *o*, is placed over the upper part of the apparatus, and over the head and shoulders of the operator, so as to exclude light from

penetrating through the ocular glass into the chamber. The plates to be operated upon, and the bath and frames are introduced through the door, *d*, and the screen or curtain, *j*, is drawn in front of the coloured glass, *b*, provided upon the inclined flexible cover, *d*.

For the purpose of convenience in manipulation of the plates, the developing basin, *h* (fig. 4), may be provided with a transparent bottom, *h*, and a cover, *i* (fig. 5), having a mirror, *i*, provided therein, so that, on the cover with its mirror being placed upon the bottom of the chamber, the light that is permitted to pass through the coloured glass, *b*, in the inclined flexible cover, *d*, is reflected by the mirror, *i*, through the transparent bottom, *h*, of the developing basin, *h*, so that the phases of development can be thus conveniently observed.

#### BECK'S VIEW-FINDER.

THE following description of Messrs. Beck's new view-finder is given by them in the patent specification:—

*A* is the body of the view finder, *B* is the mask or diaphragm having an aperture, *C*, of the same shape as the photographic plate or film, *D* is a positive object-lens or doublet lens of such a focus as to produce an

to the axis of the lens of the camera, the optical apparatus or eye lens, *E*, is placed behind and parallel with the mask, *B*, and directs the rays on to the reflector, *F*, which is placed behind the lens, *E*, and reflects the image, through the aperture, *C*, placed above it, to the eye of the observer.

In the view-finder, shown at fig. 2, the arrangement of object-lens, *D*, mask, *B*, and eye lens, *E*, is the same as in fig. 1; the reflector, *F*, is, however, dispensed with, and the viewing aperture, *C*, is placed immediately behind the eye lens, *E*. With this view-finder the image is viewed in a plane parallel with the axis of the camera lens.

In the view-finders shown at figs. 3 and 6, the object-lens, *D* (see fig. 3), is represented as a positive doublet lens, the mask, *B*, is placed at a suitable distance behind the object-lens, the mirror, *F*, is placed immediately behind the mask, and the eye lens, *E*, is placed above the mirror in the position of the viewing aperture, *C*, of fig. 1. This, the aerial image, formed by the object-lens, *D*, in the plane of the mask, *B*, is, by the mirror, *F*, reflected to the eye lens, *E*.

In the view-finder shown at fig. 4 the mirror, *F*, is placed directly behind the object-lens, *D*, and acts to reflect the image from the latter towards the mask, *B*, which is placed immediately above said mirror, the eye lens, *E*, being placed at the required distance above the mask, *B*, and quite close to the viewing aperture, *C*.

With the view-finders shown at figs. 3, 4, and 6, the image is viewed, like that shown at fig. 1, at right angles to the axis of the lens of the camera.

Referring to the view-finder shown at figs. 5 and 6, the mask, *B*, is shown fitted with a movable circular diaphragm, *K*, mounted with capability of rotating in the mask, *B*, and provided with a stud, *L*, engaging within a slot in a lever, *M*, to which the operating stud or button, *J*, is attached. The movable circular diaphragm, *K*, has an aperture, *C*, therein of oblong form, which, by means of the lever, *M*, can be placed with its long side either vertical or horizontal as may be required.

#### CINEMATOGRAPHY AT THE LAUNCH OF THE SHAMROCK.

ONE of our morning contemporaries tells us that immediately before the launch of Sir Thomas Lipton's yacht nothing whatever of the *Shamrock* could be seen by the non-privileged, but every vantage point was seized upon, and row-boats went to a premium. Some of them were chartered by artists or photographers, and cinematograph machines were placed in position betimes, a short pier jutting out offering facilities that were not to be despised, whilst piles of timber baulks, with which the yard had apparently been barricaded, was crowned by another machine camera.

When the time came for the launch, the yacht travelled quickly down the ways, her orricle still holding her, and she entered the Thames, gliding gracefully and with perfect steadiness, greeted by the shrill whistles of the tugs and the cheers of every one who beheld her. It was not for a moment or two that the *Shamrock* settled down to her light draught, for the bow was still inclined at a sharp angle, until the cradle, heavily weighted with iron as it was, sank and broke up, and the yacht gained a level deck. Her crew—forty hands—were aboard, with Captain Hogarth and Captain Ring. Two busy tugs took her in tow, and she went towards Plough Wharf, out of sight, whilst a cinematograph operator, whose instrument had at the critical moment failed, cried, ruefully, "Will she not come back again?" To his satisfaction she did, and, as the *Shamrock* repassed, the panorama, with the moving shipping, the boats in the foreground, and the people on shore, was a pretty one, and not the least effective picture of the day.

#### WEATHER "FORECAST" FOR JULY AND AUGUST.

MR. HUGH CLEMENTS favours the readers of the *Morning Herald* with the following weather forecast for July and August. Perhaps some of our readers may like to amuse themselves by seeing how far Mr. Clements' forecasts prove correct: July, on the whole, will be a very fine month, excepting the 2nd, 7th, 8th, 16th, 21st, and 24th, which will be generally or variably cloudy, the other days of the month will mostly be fine, varying from partially cloudy to cloudiness. The temperature for July will be above the average, and it will be specially hot on the 11th, 12th, and 15th, and on the 26th I anticipate that the temperature will just fall short of 100 deg. in the shade. On the 6th it will also be pretty warm. The great heat on the 26th, 10th, 6th, and 2nd will probably be productive of electrical discharges or thunder showers.

August will not, on the whole, be so fine as July, due to the fact that the oscillatory movements of the atmosphere will be greater at London, and the barometer will fall lower on the 11th and 28th especially, and on the 5th, 7th, 19th, and 24th, causing unsettled weather round those dates and a lowering of the temperature. There will be unsettled weather and occasional showers from the 4th to the 14th, on the 19th and 23rd, and from the 25th to the 28th. August will be about sixty per cent. fine, and forty per cent. unsettled and showery. It will be fine from 1st to 3rd, August, 5th, 7th to 9th, 15th and 16th, 18th, 22nd, 24th, 29th, and 31st, and on the mornings of the 20th, 26th, and 27th, and on the night and morning of the 30th.

aerial image situated exactly on the plane of the mask corresponding to the image of the camera, *E* is an optical apparatus consisting of a positive or eye lens, which enables the observer to view the whole of the image at the same time, *F* is a reflector which is fixed at the required angle, those in the drawings being represented at 45°, to reflect the image to the eye of the observer, *C* is an aperture through which the image is viewed.

In the view-finder shown at fig. 1, for viewing the image at right angles

## DOES IT PAY TO BUILD LARGE TELESCOPES?

PROFESSOR GEORGE E. HALE, a noted American astronomer, answers this question by summarising the principal advantages of a large telescopic object-glass—forty inches aperture in the special case, as compared with a smaller one of ten inches.

These advantages consist:—

1. In the fact that the larger glass is capable of giving much brighter star images, and thus of rendering visible faint stars that cannot be seen with the smaller glass.

2. In the fact that it gives at its focus an image of the object enlarged in proportion to its greater diameter.

3. In its capacity to render visible, as separate objects, the components of very close double stars or minute markings on the surface of a planet or satellite.

The principal disadvantage of the large glass is that it demands better atmospheric conditions to bring out its best qualities.

He adduces several important astronomical discoveries, which have been made possible only with the aid of large glasses, viz., the discoveries of the fifth satellite of Jupiter and of the two satellites of Mars. Furthermore, the author declares that much fine detail, which he has never been able to see with the smaller glass, is "clearly and beautifully visible" with the forty-inch glass. Also, he states, micrometrical measurements are effected with much more ease and certainty with the large instrument.

"It is practically in astro-physical research that a great telescope is advantageous. It is necessary in spectroscopic observation to have as much light as can be gathered into a single point, and for this a large glass is essential. It follows from this that great telescopes have a mission to perform. While, on the one hand, they do not possess the almost miraculous gifts which imaginative persons would place to their credit, they do possess properties which render them much superior to smaller instruments, and well worth all the expenditure which their construction has involved."

## THE ROYAL PHOTOGRAPHIC SOCIETY'S SOIREE.

THE *Soirée*, by which the Royal Photographic Society signalled its entrance into possession of its new house, No. 66, Russell-square, was given on Tuesday evening last, when the President and Council received the members of the parent and affiliated societies and their friends, a very large number of ladies and gentlemen having accepted the invitations which had been sent out. The function was in every way most successful and enjoyable, and as one went from room to room of the spacious premises one heard quite a chorus of admiration and of good wishes for the future well-being and expansion of the Society, now that it has at last secured a habitation worthy of itself and of photography.

The reception took place in the Council Room, a fine apartment, in which, and in the adjoining Meeting Room, there was displayed a selection of photographs from the Society's permanent collection, in addition to which we noticed three or four very fine pictures by Mr. A. L. Witcomb, of Buenos Ayres, which had been kindly lent by the Argentine Legation. In these two rooms there were met together almost everybody whose names are known in photographic circles, not only in London and the provinces, but also in the Colonies, the United States, and on the Continent, including many ladies. In addition to the Right Hon. the Earl of Crawford, K.T. (President), Messrs. T. R. Dallmeyer, and Chapman Jones (Vice-Presidents), G. Scamell (Hon. Treasurer), Colonel Waterhouse (Hon. Secretary), and R. Child Bayley, T. Bedding, T. Bolas, C. H. Bothamley, F. A. Bridge, W. E. Debenham, A. Haddon, Rev. F. C. Lambert, A. Mackie, J. W. Marchant, J. A. Sinclair, J. J. Vezey, and H. Snowden Ward (Members of the Council), we were able to note the names of the following, who were to be seen among the crowd who thronged the rooms and staircases: F. E. Emerson of Sydney, N.S.W., Paul Ponge (of the firm of C. P. Goetz), W. F. Carlton and E. Bausch (of Rochester, N.Y.), A. Horsley Hinton, Mrs. Snowden Ward, Mrs. Isabella Bishop, Dr. and Mrs. Charters White, Sir Benjamin Stone, M.D., H. Wilmer, F. Seyton Scott, J. McIntosh, A. W. Isenthal, Leslie Clift, E. Clifton, W. Gamble, Rev. C. J. Moncrieff-Smythe, Mr. and Mrs. Hutton Smith, J. C. S. Mummery, T. Manly, B. Speaight, W. Thomas, A. W. Penrose, Redmond Barrett, W. Wray, H. T. Malby, J. D. Mason, R. W. Craigie, E. Calland, Craig Annan, F. H. Williams, F. Ince, Edgar Scamell, E. W. Foxlee, J. J. Elliott, Sanger Shepherd, Sebastian Davis, Mrs. J. Spiller, Messrs. A. L. Spiller, Birt Acres, H. Vivian Hyde, P. B. Salmon, F. Seary, T. E. H. Bullen, W. D. Booker, J. S. Teape, Vandendriesche, R. P. Drage, Mr. and Mrs. Walter Maunder, Messrs. John Leighton, Drinkwater Butt, Amstutz, W. P. Dando, S. H. Fry, Farmer Hall, T. E. Freshwater, Mr. and Mrs. F. H. Mercer, Messrs. P. Everitt, I. Herbst, F. A. Bolton, J. H. Agar Bangh, C. Vandyk, C. S. Glass, O. Sichel, A. E. Dean, and A. S. Handford.

In the Meeting Room a selection of music was admirably rendered by the quartette band, and something of interest was provided in almost every other part of the premises. Mr. J. R. Gotz demonstrated the use of fluorescent screens in X-ray work, which proved a very attractive item, the ladies especially evincing a great deal of interest in the subject; and, in another room, an exhibition of microscopes, by Messrs. B. & J. Beck, drew many visitors, a number of wild-flower blossoms—buttercups, white

nettle, fool's parsley, dandelion, &c.—forming very beautiful objects for examination. Dr. Mackenzie Davidson's devices for stereoscopic radiography received considerable attention; and Mr. Friese-Greene, who demonstrated a method of printing without pigment or ink, introduced by the Electrical Inkless Printing Syndicate, Limited, was constantly surrounded by a throng of interested spectators. Mr. T. R. Dallmeyer's focometer was displayed, together with some old apparatus, and examples from the Society's museum, all of which were subjected to much scrutiny. The convenient dark-room and laboratory accommodation on the third floor was inspected by many of the visitors, and the library on the ground floor, where refreshments were served, was not empty.

The affair was altogether of a most pleasurable and satisfactory nature, and will, we hope, prove to be the inauguration of a period of increased success and usefulness for the Society.

## Our Editorial Table.

## LATEST VELOX INTRODUCTIONS.

MESSRS. GRIFFIN have added to their list of Velox specialities a special rough double-weight Velox, which is designed to further expedite the ready production of finished photographs. Special Velox emulsion is coated on pure white boards of sufficient thickness to obviate all necessity for mounting, and the prints made thereon present a finished appearance as soon as they are dry. It is pointed out that with double-weight Velox no curling takes place while in the solutions, and the card is handled with greater comfort than is the case with paper prints. The card prints may be carried loosely in the pocket, or for insertion in the slip-in albums. It is also pointed out that the picture is shown more effectively than with prints mounted in the usual manner, the detail being well thrown up by the perfect contact between image and card.

Velox post cards, consisting of post cards (accepted for transmission in the Postal Union), coated with special Velox emulsion, are another speciality. Messrs. Griffin observe that pictorial post cards are now becoming so popular that many who prefer the delicate tones associated with Velox will welcome this new means of embellishing their correspondence. The manipulations of the new papers are the same as with ordinary Velox.

With the title of the "Champion," Messrs. W. Boughton & Sons, Limited, of Thetford, Norfolk, are issuing a postal wrapper which may be used for sending photographs securely and safely through the post. The "Champion" wrapper is a capital one for the purpose.

PHOTOGRAPHERS who are fond of the Thames above Putney will find *The Royal Thames Guide* an invaluable book to have at hand on their excursions. It contains thirty-five diagrams from lock to lock, over one hundred illustrations of scenery, and a vast amount of local and historical information. It is published by Simpkin, Marshall, & Co., price 1s.

MR. PERCY LINDLEY, of 30, Fleet-street, E.C., sends us an early copy of the Great Eastern Railway Company's booklet, entitled *A Channel Fleet*, descriptive of the steamers now running upon the Royal Mail (Harwich) route, and also of some of the more popular Dutch, German, Swiss, and Norwegian tours arranged for this season, *via* Harwich and the Hook of Holland. From the same source we have also to acknowledge receipt of the Company's new booklet, entitled *Holidays in the Old Flemish Cities*, by Percy Lindley, describing new inexpensive holidays, *via* Harwich and Antwerp, in Flanders and the Ardennes. Both little books are fully illustrated, and the descriptive reading matter is terse and to the point. The enterprise of the G. E. R. in issuing such capital guides to short Continental holidays should, and doubtless will, find its reward in inducing large numbers of tourists to avail themselves of the excellent facilities which the Company have devised for the convenience of tourists and travellers.

## News and Notes.

MR. WILFRED EMERY, the well-known photographic dealer, trade enlarger, &c., of Soho-street and Dyne-road, Brondesbury, recently met with a very severe bicycle accident, the result of a flaw in the machine. Although badly shaken and knocked about at the time, he has now recovered, and is attending to business as usual.

UTILISATION OF SOLAR HEAT FOR POWER—Professor L. G. Carpenter, Fort Collins, Col., presented, at the late meeting of the American Association in Boston, the results of some interesting observations, continued during ten years, of the amount of solar energy received on the Western plains. These observations show an intensity of from seven to seventeen calories per square metre, from eight a.m. on sunny days. This is equivalent to from one-half to one-quarter horse power per square yard. It appears also to be as reliable as the wind, which is exclusively used as a source of power for small plants.

"THAT," cried the great painter ecstatically, as he surveyed his daughter's first attempt with a camera, where the cow was blurred into the rail fence, and the rail fence was blurred into the apple orchard, and the apple orchard blurred into the landscape generally, "that, my dear child, is not photography—that is art!"—*Puck*.

**HACKNEY PHOTOGRAPHIC SOCIETY.**—Meeting on the 20th inst., Mr. F. W. Gosling presiding.—Mr. E. H. Dunmore showed the Tellia hand camera, which was much admired by all who saw it. It is a very fine little instrument and possesses all necessary movements besides being very light and compact. The method of changing the films is very ingenious. Excursion reports and announcements were then made, and the rest of the evening was given to the examination of the excursion competition prints and the Judges' criticism thereon.

SOME Scotland-yard officials, says the Exchange Telegraph Company, have made an important discovery at the residence of a suspected forger in Camberwell. An Austrian, who has been living at Champion Hill, was recently arrested at Marseilles on a charge of uttering a quantity of forged 100-ruble Russian notes, and is now awaiting trial. At his house in Camberwell alleged incriminating documents have been found, together with extensive photographic apparatus. He is suspected of being concerned in the forgery of bank notes of the Bank of England.—*Daily Chronicle*.

THE Fourth Annual Exhibition of the Hove Camera Club will be held at the Town Hall, Hove, on December 7, 8, and 9, 1899. The open classes are: A, for pictures (any subject) which have previously gained an award; B, for pictures (any subject) which have not gained an award; C, lantern slides (any subject) in sets of four; D, for a set (or sets) of four prints by exhibitors who have never gained an award. There will also be seven Club classes. Prospectuses will be ready in October, and copies will be sent in due course upon application to Mr. C. Berrington-Stoner (Hon. Secretary), 24, Holland-road, Hove.

AN extra summer number of the *Studio* will shortly be ready, containing not only the text of the masque entitled "Beauty's Awakening," recently given before the Lord Mayor at the Guildhall, but also illustrations of a large number of the designs for the beautiful costumes, stage accessories, &c., which have been specially made for this unique undertaking by the most prominent members of the Art Workers' Guild. A feature of the number will be the numerous supplementary illustrations, consisting of coloured plates, original etchings, and lithographs, by Walter Crane, William Strang, Henry Wilson, C. R. Ashbee, T. R. Way, and others.

**DRAWINGS ON GLASS.**—Drawings cannot be made on tin or the smooth surface of glass, therefore some substance has to be applied to the surface that will render it sufficiently rough to allow the pencil marks to appear. The best material to use is a varnish prepared either from sugar or from the ingredients mentioned in the second formula given below. Sugar varnish for giving a matt surface to glass is prepared by dissolving equal parts of white and brown sugar in water to form a thin syrup, and then adding a little alcohol, and apply to the glass plates after having heated them. The film dries very quickly, and easily allows pen or pencil to be used on it. The best ink to use is Indian ink rubbed up in sugar and alcohol. To render the drawing permanent; lay over it also or mastic varnish.

**SOCIETY OF ARTS MEDALS.**—The Council of the Society of Arts have awarded the Society's silver medal to the following readers of papers during the session 1898-99: Professor George Forbes, F.R.S., for his paper on "Long-distance Transmission of Electric Power;" C. H. Bothamley, F.C.S., "Photographic Developers and Development;" Dixon H. Davies, "The Cost of Municipal Enterprise;" James Swinburne, "Nernst's Electric Lamp;" J. H. Collins, "Cornish Mines and Miners;" Philip Dawson, "Electric Traction;" Walter Hunter, M.Inst.C.E., "London's Water Supply;" Sir W. H. Preece, F.R.S., "Etheric Telegraphy;" Colonel R. Carnac Temple, C.I.E., "The Penal System at the Andamans;" Sir John Scott, "Judicial Reforms in Egypt;" Archibald Little, F.R.G.S., "The Yang-tse Basin and the British Sphere;" Stephen Webb, "Intarsia, or Inlaying;" J. Starkie Gardner, F.G.S., "The Revival of Tradesmen's Signs."

**COMPRESSED OXYGEN FOR COMBUSTIONS.**—The use of compressed oxygen in elementary organic analysis is recommended by F. G. Benedict and O. F. Tower (*Journ. Am. Chem. Soc.*, 21, 390), who find that this modification materially shortens the process in making carbon and hydrogen determinations. The compressed oxygen supplied in steel cylinders is comparatively dry and free from carbon dioxide, so that its purification is easy to accomplish. The carbon dioxide is absorbed by soda lime in a small U-tube, one such tube sufficing to remove the impurity completely for more than twenty-five combustions. The gas is next passed through a drying apparatus consisting of a cylinder about 12 cm. high, half filled with concentrated sulphuric acid, through which the oxygen bubbles, thereby indicating the rate of flow. A small U-tube containing pumice stone drenched with sulphuric acid is used to retain any remaining trace of moisture. As the gas enters the combustion tube its flow must be regulated. A rubber tube, leading from the cylinder, connects with a T-tube, one end of which dips one inch under mercury in a small bottle fitted with a rubber stopper having two holes, the second of which is left open. The other end of the T-tube is connected by a rubber tube to the purifying apparatus, which is, in turn, connected to the combustion tube by rubber tubing furnished with a pinch cock. On opening the cylinder valve slightly the oxygen flows out and, passing through the driers, produces a bubbling in the sulphuric acid cylinder. The pinch cock is now closed until the desired rate of flow is obtained, any excess of gas escaping through the mercury trap, and the cylinder valve is finally adjusted so as to prevent any appreciable loss of oxygen.

## Patent News.

THE following applications for Patents were made between June 12 and June 17, 1899:—

- APPARATUS.**—No. 12,276. "Improvements in Photographic Apparatus." E. J. CLIFFORD.
- PACKING CHEMICALS.**—No. 12,337. "Improvements relating to the Packing and Dispensing of Minute Quantities of Photographic Chemicals." J. J. GRIFFIN & SONS (Limited) and F. H. IBBETSON.
- DEVELOPING WITHOUT THE USE OF A DARK ROOM.**—No. 12,371. "Improvements in and relating to Means for the Development and Sensitising of Photographic Plates, Papers, or the like without the Necessity of the Dark Room." S. QUINCEY.
- DIAPHRAGMS.**—No. 12,416. "Improvements in Diaphragms or Stops with Variable Apertures for Objectives applicable for Photography and the Projection of Pictures." Communicated by M. Radais and M. Stiasnie. W. P. THOMPSON.
- STORING PLATES AND FILMS.**—No. 12,441. "Improvements in the Mounting, Storing, and Manipulation of Sensitised Plates and Films, and in Apparatus connected therewith." J. E. THORNTON.
- ANIMATED PHOTOGRAPHY.**—No. 12,497. "New or Improved Method and Means of Changing (either rapidly or otherwise) the Sensitive Surfaces in Taking Photographs or for Displaying the Views in Rapid Succession in Animated Photography or the like." R. H. EDWARDS.
- ANIMATED PHOTOGRAPHY.**—No. 12,511. "Improvements in the Means and Apparatus for Reproducing Animated Scenes by Projection on to Screens or Surfaces." Communicated by the Société Internationale d'Etudes Industrielles, France. C. D. ABEL.
- LIGHT-FILTERS.**—No. 12,515. "Improvements in the Manufacture of Selective-colour Light-filters for Photographic Optical Purposes." G. SELLE.
- COLOUR PHOTOGRAPHY.**—No. 12,516. "Improvements relating to the Sensitising and relative Sensitive Adjustment of Photographic Plates or the like for use in Colour Photography, and to the Measurement of Time Exposure of said Plates." G. SELLE.
- COLOUR PHOTOGRAPHY.**—No. 12,517. "Improvements in the Formation of Films for Use in Colour Photography." G. SELLE.
- CAMERAS.**—No. 12,580. "Improvements in Photographic Cameras." G. HURKA.
- PRINTING PAPER.**—No. 12,585. "Improvements in Photographic Paper adapted for Printing Out and other purposes." Communicated by A. Schwarz. THE ROTARY PHOTOGRAPHIC COMPANY (Limited).
- CAMERAS.**—No. 12,623. "Improvements in or relating to Photographic Cameras." A. D. WILLIS and L. W. MENCH.
- CAMERAS.**—No. 12,644. "Improvements in Cameras." J. E. THORNTON.
- TINTING PHOTOGRAPHS.**—No. 12,678. "An Improved Method of Tinting Photographs." Complete specification. T. T. BAKER and M. S. BERGER.
- X-RAY METROSCOPE.**—No. 12,685. "An X-Ray Metroscope." E. W. H. SHENTON and A. E. DEAN.
- POCKET CASE.**—No. 12,698. "Photographic Utensil Pocket Case." Communicated by A. V. C. Mayall. Complete specification. H. H. LEIGH.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
3.....	South London .....	{ Some Methods of Control in Photographic Printing G. J. T. Walford.
4.....	Gospel Oak .....	{ Cloud Photography C. Stone.
5.....	Oldham .....	{ Excursion: Lichfield. Leader, W. A. Nash.
5.....	Photographic Club .....	{ Binocular Vision and the Stereoscope Thomas Bedding.
8.....	Ashton-under-Lyne.....	{ Excursion: Ripon and Fountains Abbey Leader, The President.
8.....	Hackney .....	{ Excursion: Ladies' Day. Leaders, The President and W. F. Fenton-Jones.
8.....	Kingston-on-Thames .....	{ Excursion: Leatherhead to Box Hill Leader, O. Holford.
8.....	Liverpool Amateur.....	{ Excursion: Nant-y-Frith or Farndon.
8.....	South London .....	{ Excursion: Wanstead Park. Leader, G. Brown.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 22.—Mr. R. P. Drage in the chair.

The first business of the meeting was the nomination of officers and Committee for the ensuing session. The names proposed will come up for ballot at the next meeting, with certain notices of alteration of rules for consideration.

Messrs. F. Kellow and H. C. Rapson were appointed Auditors of the accounts. Mr. T. E. Freshwater was elected to fill the post of Delegate to the Affiliation vacated by Mr. E. Bayston, Mr. S. H. Fry being the other delegate.

A hearty vote of thanks was conveyed to Mr. A. L. Henderson for his hospitality of the previous week on the occasion of the garden party at his house at Brimsdown.

Mr. A. L. HENDERSON related that in a prescription which he had recently had prepared there occurred the name of a substance called lysidine, a preparation by Professor Ladenburg, of Germany. He found that the liquid was very much like caustic soda or potash, and it occurred to him that it might serve as the alkali in pyro development. A solution of—

Pyro.....	4 grains,
Water .....	2 ounces,
Lysidine .....	3 drops,

was made up, and found to answer admirably, no sulphite being used to keep the solution clear. After use, the mixture was left in an open measure for some time, but it only turned to a pale sherry colour, without, he believed, losing in developing power.

Mr. PHILIP EVERITT spoke of the new platinum paper Platona, which he thought would be welcomed. He had tried the new paper against the old, and passed round two prints, between which, however, it was difficult to find any difference, although the platinotype print had been made some nine years. Not having any potassium phosphate at hand for the development of the platona prints, he used a cold ten per cent. solution of oxalate of potash.

Mr. S. HERBERT FRY said that some tests which he had made with the new paper against the English and Jacoby's German paper were quite satisfactory.

Mr. J. S. TRAFFE drew attention to some notes by Professor Namias, published in a recent letter to this JOURNAL, in which the use of permanganate of potash and sulphuric acid in dilute solution as a reducer was mentioned. It was found that the action was analogous to that of persulphate of ammonium, but there was no ground to suppose that the silver was deposited on the image. Mr. Teape made up a solution which, while acting as expected, produced a stain. It was then modified to the following proportions:—

Permanganate of potash .....	3 grains.
Sulphuric acid.....	20 minims.
Water .....	24 ounces.

This bath effected a considerable reduction in the dense parts of the image before touching the weaker portions, and only slightly tinged the plate.

A discussion took place regarding the developer kachin and its power of working satisfactorily in combination with the hyposulphite fixing solution. In response to a suggestion that it was not, or likely to be, a practicable method of developing and fixing together, Mr. CHILD BAYLEY said that he had exposed as for ordinary development, with separate fixing, a number of plates, which he developed and fixed together in this way, and the results were in every way as good as he should have expected in the more orthodox manner.

Mr. HENDERSON, in the course of some comments upon the innovation, said that some plates contained more iodide than others, and in the ordinary way took a long time to fix. A mixture of hypo and cyanide of potassium greatly accelerated the fixing, the latter ingredient more easily dissolving the iodide salt.

#### PHOTOGRAPHIC CLUB.

June 21.—Mr. F. A. Bridge in the chair.

An interesting book with some well-executed collotypes of scenery on the route of the St. Gothard Railway, by MM. A. Berger et Cie., of Nancy, was passed round for examination.

Mr. John Nesbit showed a stereoscopic pair of negatives taken on rollable film, and afterwards separated and mounted in the correct position for printing, without any subsequent cutting being required. He wished to know how best the films could be stuck upon the final glass support, about which there was some difficulty.

The claims of gelatine were investigated, but thought wanting, and it was thought that some alcoholic varnish or cement that would bond with the celluloid of the film as well as with the glass would answer best, dilute shellac varnish being named as probably likely to serve.

North Middlesex Photographic Society.—June 19, Mr. H. W. Bennett in the chair. Mr. J. McIntosh gave a demonstration on

#### REVERSED NEGATIVES BY MEANS OF PERSULPHATE OF AMMONIA.

The method of procedure was briefly thus: A dry plate is placed in contact with the negative of which a reverse is required, and exposed about twice as much as if a good transparency was desired. The development is carried on until the image is right through the back, rinsed, and placed in a five per cent. solution of persulphate of ammonia until the metallic silver is completely removed. It is then placed in a solution of sulphite of soda for a few seconds to free it from the persulphate, and the bromide of silver remaining on the plate is reduced by development as in the first operation. It is then safer to immerse in hypo to remove any traces of bromide unreduced, as it would change in the light. All the operations after the first development may be conducted in daylight. This method would appear, if properly carried out, to give a better and truer rendering of the gradations of the reproduced negative than either the method of stripping the film and transferring, or by excessive exposure of a dry plate, to secure reversal, i.e., a negative from a negative. Mr. Macintosh carried through the demonstration very successfully. For the developer he used the newest reagent for that purpose, kachin, which gave a pleasing image of a brown-black colour, and did not stain like metol, &c. The negative used was one developed and fixed in one operation, metol being the developer.

Bath Photographic Society.—The second excursion of the season took place on Saturday, June 17, to the picturesque town of Malmesbury. The party travelled by the Great Western Railway, arriving at the splendid pile of Abbey ruins shortly before three o'clock. Without delay the streets, usually of a quiet character, became a scene of bustle and interest, for the Bath Photographic Society had captured the town and were busy securing views from

every advantageous point. Cameras and paraphernalia were everywhere in evidence. The Abbey contains very good examples of Norman work, especially the great arch (north-east) and the south door. Examples of Transitional and Gothic are likewise plentiful. History relates of the Abbey, dating from the seventh century, that founded in 680 by Alhelm, after a long period of much usefulness, it fell, at the dissolution, into its present state of decay. A fine Market Cross—a useful lounge for the lazy—was built in the reign of Henry VII. Henry VIII. sold the Abbey property to a clothier named Stump, who is reported to have used it as weaving workshops, and afterwards presented a portion to the town for the purposes of a parish church. Several interesting photographic subjects are situated close to the Abbey, including an Elizabethan house and other ancient buildings. The streets, too, are of a type conducive to picture-making. A successful afternoon's work was followed by tea at the King's Arms.

Bolton Mutual Photographic Society.—June 23, Mr. J. Phetheau presided.—The object of the meeting was to have a social chat and compare notes over the summer rambles, with a view to make them as attractive as possible. The Society's trip to Chester was definitely fixed for Wednesday, July 19. A letter was read from the Hon. Secretary (Mr. T. H. Heyes), tendering his resignation on account of ill health. It was accepted with regret, and a resolution passed thanking him for his past services, and hoping he would be speedily restored to health. Mr. A. W. Roscoe was appointed Secretary until the annual meeting in October.

#### FORTHCOMING EXHIBITIONS.

1899.

Sept. 22–Nov. 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, Dudley Gallery, Piccadilly.

„ 25–Nov. 11..... Royal Photographic Society. Hon. Secretary, Colonel J. Waterhouse, 12, Hanover-square, W.

October 18–24 ..... Croydon Camera Club.

„ 22–Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.

#### Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE CONVENTION—A DARK ROOM AT DISPOSAL.

To the Editors.

GENTLEMEN,—As the Annual Convention of Photographers will shortly take place at Gloucester, will you allow me space to say that I shall be pleased to place at the disposal of any friends who may visit Stroud on that occasion a dark room at one of my studios for changing plates, &c. Stroud is twelve miles from Gloucester, and is noted for its magnificent scenery, and is approached from Gloucester by Midland and Great Western Railways. I shall also be pleased to point out places of interest in and around Stroud worth photographing.—I am, yours, &c.,  
Lansdown and Rembrandt Studios, Stroud. JOSEPH SMITH.

#### “FREE LANCE” AND MR. EVERITT.

To the Editors.

GENTLEMEN,—I am really disappointed in Mr. Everitt. His defence of his dictum that it was possible to get a picture of the hair of a galloping horse in one five-hundredth of a second resolves itself into a suggestion that the animal should be taken “end on.” And this, too, after I had classed him and Mr. Ruskin together as dialecticians! Mr. Everitt is by way of being a judge of wit, but we have here cunning, not wit, and one wonders why he intervened at all in the original debate if his dictum had no more value than he now shows it to have. I suppose his remarks about a galloping pace are intended to be humorous. I gave him every opportunity, by not over-pacing his horse, of qualifying his statement without making the present ignominious surrender; but I am quite prepared to show that a horse—let us say a hunter—that could for long follow the hounds at such a speed would be a “clinker.”—I am, yours, &c., FREE LANCE.

#### PHOTOGRAPHS REGISTERED:—

F. C. MacMahon, 23, Academy-street, Inverness.—Photograph of Scottish terrier dog

H. Vert, 67, High-street, Dudley.—Three photographs of the Gues' Hospital, Dudley.

A. G. Bolwell, 28, New King-street, Bath.—Cabinet photograph of E. Thorold, Esq., M.A. (deceased).

J. W. Wale, Wellington House Studio, West Hartlepool.—Two cabinet photographs of John T. Taylor.

G. W. West, The Studio, Rottingdean, near Brighton.—Photograph of the home of the late Sir Edward Burne-Jones. Photograph of the residence of Mr. Rudyard Kipling, Rottingdean. Photograph of St. Margaret's Church, Rottingdean.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

RECEIVED.—F. DANKS; AMATEUR; P. RAYNER; J. WHEELER; INTAGLIO; R. A. BREMAN; and others. In our next.

A. UNDERHILL.—The address is Great Windmill-street, W.

T. T.—1. Dissolve 1 grain of gold in every 100 minims of water, and the bath will contain 12 grains. 2. Twenty-four hours. 3. Yes.

T. G. G.—We do not think your friend need have any fear of the firm's threats. Unless there is a stamped agreement, there is no ground for an action.

DAGUERRETYPE.—EXPERIMENTALIST. We cannot say where you will be able to obtain Daguerreotype plates at the present time. No one has stocked them since that process died out.

DIFFUSION OF FOCUS.—S. MARCHMONT. The portrait stigmatic lens of Dallmeyer is provided with the means of introducing spherical aberration, "diffusion of focus," at will, the same as with the other portrait combinations.

OLD PLATES.—W. NIEL. The two plates sent show that they are very old, and are practically worthless. This is a risk that must always be run in buying "job lots." Of course, under the circumstances, the makers of the plates are not held responsible.

LENS FOR HAND CAMERA.—T. WATSON. The only way to obtain pictures with a wider angle is to use a lens of shorter focus. A lens of six-and-a-half-inches focus is long for a quarter-plate hand camera. Get one of five-and-a-half-inches or shorter focus.

STAINED PRINTS.—B. & Co. The stains are most undoubtedly caused by carelessness in the work, whatever your printers may say to the contrary. Why not, to some certain extent at least, supervise the work yourselves? You would then see where the fault lies. That, of course, we cannot indicate by merely seeing two or three prints with stains upon them.

MOTTLED ALBUMEN PAPER.—H. A. The reason the paper prints mottled is that the bath upon which it was sensitised was too weak in silver for the amount of chloride in the paper; or it was not floated long enough upon the solution. If you sensitised the paper yourself, increase the strength of the bath by at least ten grains of nitrate of silver to the ounce.

TONING DIFFICULTY.—T. WADE writes: "I cannot get my prints to tone. They will not tone at all, no matter how long they are left in the bath. I use the acetate bath, and have had no trouble till just lately. I have always used an enamelled-iron dish for the solution, and the other day I noticed that the enamel was cracked in places. Do you think that has anything to do with it?"—No doubt, it has all to do with it. The exposed iron reduces all the gold there is in the solution.

HERBERT NORRIS.—If you send our publishers 1s. 7d. and three prints of the subject to be registered, they will do the useful for you. The words, "By Royal Appointment," can only be used if you have a royal warrant, which you have no chance of obtaining. "Distinguished patronage" is a meaningless phrase, which anybody can use. Coats-of-arms are matters for the Herald's College. Take our advice, and don't bother your head about such things; they do not help you in business one jot.

COPYRIGHT.—R. W. B. If the photograph is copyright in Germany, and there is little doubt it is, it is also copyright here, although it is not registered at Stationers' Hall. Under the International Copyright law, any picture made copyright in Germany, or other countries to the Convention, become, as a matter of course, copyright in England; also, any picture made copyright in this country becomes also copyright in other countries. Hence, you see, it would be illegal to reproduce any of the photographs in question.

COPYRIGHT.—H. A. WARD writes: "I have to photograph the interior of a large room, on the walls of which are several engravings, framed, that I know are copyright, and they will show in the picture if they are left where they are. If they are removed, the room will not look as when the meetings are held in it, and that is what the Society want specially. Will you kindly advise me on the subject?"—So long as the object of the photograph is only to show the room as it is, and not to make a distinct reproduction of the engravings, there will be no infringement of the Copyright Act.

ENLARGING.—NOVICE writes: "I want to enlarge some of my quarter-plate hand-camera negatives on bromide paper, using the light from a north window that I have blocked up for the purpose. I want to make the enlargements from whole plate to 12x10, none larger. Will you please say what size condenser I should get, and how it should be fixed at the window?"—No condenser is required, it would be useless. Simply fix the negative up at the window, or the opening left, with a piece of ground glass an inch or two behind, and reflect the light upon it by means of a sheet of white cardboard placed at an angle of 45° outside.

BOOK OF VIEWS.—W. C. BAX asks: "Can you tell me the best way to go about making a book of views—about half a dozen—so that the book can be opened and the views brought out in a line? Where could I get the covers? What process and manipulation, and probable cost of each, quarter-plate size? Should be glad of any information your experience can supply me."—In reply: You might obtain the covers from Marion & Co. We should recommend you to have half-tone blocks made, cost about 10s. each. Printing and paper you would have to get contracts for. We should advise you not to attempt the work yourself.

HALF-TONE ETCHING.—AJAX says: "I want instruction in the use of the ruled screen in taking photographs for making blocks from. Can you tell me of a book on the subject; also where can I buy such a screen? I do not find it mentioned in the lists issued by any of the dealers in photographic goods. I think the subject has been dealt with in the JOURNAL, but I cannot find the reference."—In reply: Suitable screens may be obtained from Messrs. Mawson & Swan, Soho-square, W.; Penrose & Co., Upper Baker-street, W.C., and other firms. *The Half-tone Process*, by Verfaesser, published by Percy Lund & Co., Bradford, would be a suitable text-book.

BOOKS WANTED.—INQUIRER asks: "Will you be so kind as to let me know, through the columns of your valuable paper, of a thoroughly practical book on photographic chemistry, which does not go too deep for one who has practically no knowledge of chemistry, though a fair acquaintance with the common photographic manipulations? I should also be very much obliged to know of one dealing with the most-used printing processes in a way suited to one who wishes to become a good all-round printer from a professional point of view."—In reply: Leaper's *Materia Photographica*, Townsend's *Chemistry*, Abney's *Instructions* should give you the desired information.

ENLARGING.—H. TOPPING writes as follows: "I want to enlarge some half-plate negatives to 12x10 on bromide paper, using daylight from a north window. I have only two lenses that are large enough for the work; one is a portrait lens of about ten inches' focus, the other is a Dallmeyer Stigmatic, Series II., of nine inches focus. Which of the two would be the best to use? I fancy the portrait lens would be the quicker."—Use the Stigmatic, because it has a flat field, with even illumination to the corners. The portrait lens would be the quicker if used with its full aperture, but then it has a round field, also it will not yield even illumination from the centre to the edges of the picture.

DISCOLOURED OPALS.—GORDON says: "I here enclose an opal picture, which, you will see, has become blue all over the shadows and brown and smoked-like more or less over all the figure. I do a considerable number of opals, and lately a few of those which I have done from two to four years ago have been brought back to me in a similar state to this one; some of them even a good deal worse with this blue and brown fog. I will be extremely glad if, through your paper, you can throw any light upon the probable cause of it, as I am very much annoyed and it is a very serious matter, affecting the permanency of my work, as, however careful I am, I do not know what one may go wrong this way. I have not seen or heard of any of them changing this way in less than two years, but those which do go wrong gradually get worse, until they are quite useless. They are developed with rodinal, and thoroughly fixed and washed. I do not use any acid after development, as they do not seem to require it, being quite pure in the whites. Do you think being dried along with negatives, standing high up on a rack in the dark room, with a small jet of gas fixed six feet below, could possibly have any effect upon them? Of course, it is not for the drying of them I use the gas, but for the negatives."—In reply: A very likely cause is imperfect fixation; but in these instances the pictures may have been kept in an atmosphere charged with gaseous impurities, which have attacked the image.

STARTING IN BUSINESS.—GIPSWY writes: "1. I have purchased a small plot of ground on which to erect a house and studio and permission to erect a shop for the sale of photographs and 'things legitimate to a photographic business only.' Of course, I want to sell everything I legally can. This is a seaside village. I can sell photographs, picture frames, the various printing papers, mounts, plates, and things of this kind. As I am a stranger, perhaps you could tell me a few other things that could be sold. Could I have an apartment agency and circulating library, as I should not sell anything, or a mutoscope placed outside the shop door? I shall be glad of any information. 2. Can you tell me the best book on photogravure? Can the art be learned from a text book, and learned by a woman? Is the first outlay expensive? I wish to issue some cheap guide books, and thought this process could be adapted for the purpose. 3. How should I get in touch with plate and paper-makers? Should I write them, or do travellers call? 4. I should like to get a letter of thanks for photographs from the Queen, as this is a draw with many people. I see one photographer near by has some, but I sent two or three sea studies to the Queen, and had them returned with letter to say the Queen was unable to receive presents of this kind. Is it of any use to try again? If so, in what way?"—In reply: 1. We suggest that you study the advertisements of our ALMANAC for 1899. These refer to goods which we should consider legitimate to a photographic business. By all means have a mutoscope. 2. Denison's book, published by Iliffe & Co., 3, St. Bride-street, E.C. It should be supplemented by practical instructions. For cheap guide books the half-tone process would be best. We should not recommend you to take up photogravure for the purpose. 3. Write them. Their addresses are given in our advertisement columns week by week. 4. Useless trying unless you have something of very special interest to send Her Majesty. Write again if we can be of further help.

## EX CATHEDRA.

IN the course of the present summer, a new book on Tele-photography, by Mr. Thomas R. Dallmeyer, will be published. We have been given the opportunity of glancing at the advance proof-sheets of the work, and it appears to us that the author has developed the theory of the tele-photographic lens system in such a manner that the photographer with whom anything but the most elementary optics are not strong points, can easily grasp the fundamental principles of this method of image formation. Nor does Mr. Dallmeyer overlook the advanced worker in his book, which contains some matter in relation to its principal theme not hitherto published. The illustrations, which are both striking and attractive, are from negatives by Mr. Dallmeyer himself, and they show, with that marvellous realism of which one never seems to tire, the effect of substituting a tele-photographic lens for one of a normal length of focus.

MR. DALLMEYER'S long-distance tele-photography was accomplished on the south coast, the Isle of Wight, twenty-two miles across the water from Boscombe, offering a capital study for

the purpose. It is noteworthy that, although practical tele-photography may be said to have originated in this country, the fullest advantages of the enormous possibilities of the system have only been availed of abroad by Continental governments and men of science. Such a subject as a mountain from a distance of fifty-two miles (*vide* the Bolsonas picture of Mont Blanc) may be looked upon as a practical impossibility in Great Britain, owing to the fact that the atmosphere of these islands is rarely clear enough to allow of a sharp image at such a distance being obtained. Hence we are disposed to regard Mr. Dallmeyer's tele-photograph of the Isle of Wight, across twenty-two miles of water, as an achievement deserving of more than passing notice. To the best of our recollection, no home-produced photograph of an object situated at such a great distance from the camera has yet been shown. If we are in error here, we should be glad to have particulars.

\* \* \*

THE Select Committee of the House of Lords on the Copyright Bill met again on June 30. Lord Monkswell presided. Colonel Waterhouse, Hon. Secretary of the Royal Photographic Society, produced the resolution of the Society, protesting against any interference with the Copyright Act of 1862. Photography, he pointed out, was not a merely mechanical process, and there could be as much feeling in a photograph as in a painting. Lord Knutsford said he supposed they had a sentimental objection to being put on a different footing from painters. The witness said what they objected to was the placing of photography on a distinctly lower grade. Mr. Gambler Bolton took the same view, and gave instances in which his photographs had been drawn and published as original drawings. Lord Hatherton said there was a growing custom of photographing houses and grounds for publication in newspapers. Had the newspaper a copyright in that photograph? He had seen the word copyright added to the picture. Mr. Cutler, Q.C., said there could be no copyright in such a photograph. The Chairman: In many cases they put copyright where there was no copyright at all. The witness, in conclusion, said he thought that photographers had as much right to be considered artists as painters and sculptors. Mr. Elliott, of Messrs. Elliott & Fry, Mr. Mitchell, Manager of the London Stereoscopic Company, and Mr. Frith, of Reigate, also gave evidence, and the Committee adjourned.

FOR the convenience of those of our readers attending next week's Gloucester meeting of the Convention we print elsewhere in this issue of the JOURNAL the synopsis of the official proceedings. There is also in our Correspondence columns a letter from the Hon. Secretary (Mr. Bridge) relating to excursion trains from London. It will also be observed that Mr. Alfred Watkins is prepared to demonstrate during the week a "time" method of developing Spectrum plates. We hear, too, that there is a likelihood of the Secco and Wellington & Ward stripping films being demonstrated as occasion may arise. Those of our friends who may wish to communicate with us personally or by letter during the Convention should address us at the New Inn, Gloucester.

\* \* \*

OF those who attended last week's *Soirée* of the R.P.S., nobody was more pleased to mark the success with which it went off than ourselves, who first publicly mooted the idea of such a house-warming in these pages on May 5. Among the Society's treasures which were displayed on that occasion, and to which reference was not made in our report, were a series of Dr. Emerson's famous East Anglian landscape and figure studies, which have not been publicly shown except in book form for some years past. Many of the visitors at the *Soirée*, who have only taken up photography comparatively recently, were not familiar with Dr. Emerson's work, and, as they turned over these pictures, anxious questions as to who they were by, remarks as to how like Clausen in style, and so on, from delighted critics, caught the ear.

\* \* \*

It is to be hoped that these very fine works which, besides being splendid examples of pure photography, show a boldness and mastery of pictorial effect in figure and landscape work probably unapproached by the productions of any living photographer, will in due course be rescued from the oblivion of the portfolio, suitably framed, and hung in the Royal Photographic Society's rooms. To our thinking they transcend in interest much of the more modern work that has been acquired for the permanent collection, and they have the additional value of emphatically marking what we may be allowed to term the renaissance of pictorial photography fourteen years ago.

\* \* \*

MESSRS. BERGER & Co. of Southill Park, London N.W. announce a new method of imparting "natural colours" to photographs. These results are said to be obtained by a new printing-out paper. It is stated that the prints are finished in exactly the same way as those upon ordinary P.O.P., and the tints may then be instantly developed upon any desired part of the picture with the utmost ease, rapidity, and certainty. It is also stated that no dyes, colours, pigments, or special apparatus, are required.

\* \* \*

MR. George W. Tottem, F.R.P.S., of 6, The Boulevard, High-road, Balham, S.W., in sending us for inspection a beautiful portrait of a pretty little child, draws attention to the print as a specimen of mounting, it being attached to the mount in a way possibly unknown to many. He adds: "We all know amateurs as a rule get tied into knots when they start putting a 'Mountant' on their prints, and they fall back on to those al-p-shod things, 'Slip Mounts.' Now, being a dealer, I ought

to say nothing about them; but, as I *do object* very strongly, I don't mind saying so. Consequently I demonstrate my method of mounting several times a day throughout the week. This is the scheme: I take a large glass (cutting shape, say), spread mountant, lay print down, rub well into contact, peel off, lay on mount and rub well down, which is as simple and quick in practice as it is to write. The advantages are that one's fingers do not get messed up, only enough mountant is left on print to make it adhere to card, no dirty edges, no finger marks on face, and, in the case of glazed prints, no backing. I can mount a 23 x 17 enlargement just as readily as a pocket Kodak print in this way; and so do those to whom I have shown the method." Many an amateur photographer may be glad of Mr. Tottem's very useful hint on mounting. From practical experience of it we can recommend it.

\* \* \*

MR. J. CRAIG ANNAN informs us that the work of organizing the Great International Exhibition at Glasgow in the year 1901 is already well in hand. Mr. Annan himself is the convener of the committee which has charge of the Photographic Section. The Exhibition buildings will be located at Kelvingrove Park, where the group of the Photographic Convention was taken in July last year. It is expected that the display of photographs will be the largest yet brought together. The last great International Exhibition was held in Glasgow eleven years ago, and it will be remembered as a conspicuous success. Glasgow hopes in 1901 to break its own record.

\* \* \*

MR. S. H. FRY, of 12, South Villas, Camden-square, N.W., has been good enough to send us an enlarged print in platinum from one of the groups taken by Mr. A. L. Henderson on the occasion of that gentleman entertaining the members of the London and Provincial Photographic Association at his house, Brimsdown, Middlesex, a few weeks ago. The print is a very fine one on Platona paper, and this, combined with the fact that there are many excellent portraits of our fellow-members of the London and Provincial in the group, makes Mr. Fry's picture of the greatest interest to us as a pleasant memento of a pleasant outing.

\* \* \*

AFTER several years' service, Mr. T. E. Freshwater, F.R.M.S., yielding to the paramount claims of business, has found himself obliged to resign the Hon. Secretaryship of the London and Provincial Photographic Association. He leaves the London and Provincial in a vigorous position and with a good balance at the bank. In a quiet and unostentatious way Mr. Freshwater got through a great deal of good work during his tenure of office, and we are pleased to learn that the members intend asking him to accept some tangible token of their appreciation of his services. The growth of the claims on our time render it impossible for us to be so frequently present at the London and Provincial meetings as in past years, but we gladly testify, from the capital reports and papers that so often appear in our columns, to the excellent and informative nature of the discussions that still, as in days of yore, take place at the London and Provincial. In the maintenance of that Association at the high intellectual level it has invariably touched during its history Mr. Freshwater has borne a useful and prominent part, and we desire to join its other members in thanking him for his work as its Hon. Secretary and Treasurer.

MR. HARRY WADE, of 29, Blackfriars-street, Manchester, asks us to state that on Messrs. Wellington & Ward's behalf he is prepared to deliver before photographic societies a demonstration on their new film, which is shortly to be put on the market. Secretaries are requested to make early application to him for dates. Mr. Wade is a skilful photographer, and may be relied on to do the new film every justice.

\* \* A METHOD of making enlarged negatives from an enlarged transparency of the original negative forms the subject of our leading article this week.—Those interested in Professor Wood's method of colour photography with diffraction gratings will find a further contribution on the subject which indicates several possibilities of this interesting process.—The action of coloured substances on dry plates, which Mr. Vincent treats of, takes up the line of work which has recently occupied so much of Dr. W. J. Russell's attention, and shows that ozone has a large influence in producing "photographic pictures in the dark."—Mr. Bothamley's remarks on the Ilford Platona paper, of which we continue to hear very favourable accounts, will be useful to those experimenting with the new paper.—Mr. Debenham's paper, on "The Illumination of the Dark Room," contains many points of practical interest for dark-room workers. The reference to the effect of working with different coloured lights on the eyesight and nerves deserves particular attention.—In the article entitled "Actinograms and a Self-recording Actinometer," our contributor, Mr. John A. Randall, describes what appears to be a very ingenious instrument for taking continuous records of the actinic value of light.

#### A NEGLECTED SYSTEM OF ENLARGING.

IN the issue of last week there is a paper, read before the Photographic Society of Philadelphia, on reproducing and enlarging negatives. This paper, like many others that have been read in this country, deals more particularly with the methods of making the transparency and general formulæ. In the majority of the papers which are read on this subject transparencies by contact, either on dry plates or by the carbon process, have been advocated, while another, and in many cases a much better, system has been quite overlooked, though its utility has more than once been referred to in these pages. The method was some years ago vended as a secret process by a then well-known photographer, who realised a tolerably good sum by the business. In a word, the system is this:—

Instead of making the transparency by contact printing, it is made direct as the enlargement, and from that the negative is made by contact printing. Let us now consider the advantages of that method of procedure. It will be obvious that, as the actual amplification is made direct from the original negative, the utmost sharpness is secured, and only what exists in that is shown. When a transparency is made by contact printing on a dry plate, unless the glass, as well as that of the original negative, is perfectly flat, absolute contact in all parts is not secured, and consequently there is a loss of sharpness to begin with. It is manifest that any defect, mechanical or otherwise—minute spots or specks in the film, for example—granularity of the image, or other imperfections, will be magnified in the enlarged negative, yet they do not exist in the original. If, however, the plate upon which the enlarged transparency is

made contains similar defects, they, not being magnified, will not be noticeable.

One of the great advantages of this system of making enlargements is the great scope it gives for improvements by retouching, which could not be done on a contact transparency by reason of the fact that, whatever work was put upon it, it would be magnified in the enlargement, and so become very conspicuous in the finished result, however skilfully and finely the work may be done. Here is a further example of the advantage of the enlarged-transparency method: Given a weak or feeble original, in the transferring the shadows and darker half-tones can easily be strengthened by washes of water colour, or by stippling with black lead, and much of this work can be roughly done on the back of the plate if that be given a coating of matt varnish. The retouching of a transparency is easier to a novice than the retouching of a negative, by reason of the lights and shades being the same as they are in the finished print, and its being of the same size, in fact a counterpart of it. In this way a vigorous transparency, so far as the shadows and darker half-tints are concerned, may be made from a feeble original, leaving the light and lighter half-tints to be strengthened in the negative; and, as with the transparency, much of the bolder work can be quickly done on the back of the plate.

The negative from the enlarged transparency may be made on a dry plate by contact printing, or, if it is required reversed as for single transfer carbon printing or other purposes, it may be made by the carbon process in the same way that carbon transparencies are made.

With this system it is better that no attempt be made at retouching on the original negative; that is best left for execution on the enlarged transparency and the negative from it, because it can be more easily and quickly done, while the result will be better in the end. It is, as most know, very troublesome to ameliorate the amplified retouching on small negatives in an enlarged one so that it is not conspicuous. By this system of enlarging, as we have just intimated, it is a very simple matter to make vigorous enlarged negatives from weak and feeble ones, and, conversely, to obtain harmonious ones from harsh originals, by supplementing what can be done in skilled hands by exaggerating or subduing the contrast in the developing of the image, by hard work quickly and easily applied. As a practical illustration of the value of this method of producing enlargements, it may be mentioned that many, if not all, the very fine enlarged pictures of the lions in the "Zoo," published some years ago by Messrs. Dixon & Son, were produced in this way.

In the paper that suggested this article reference is made to the reproduction of negatives the same size as the originals. We happen to know that, some years ago, it was the custom with more than one portraitist, when a number of negatives of a subject had to be reproduced for publication portraits, for them to make an enlarged transparency—12×10 or 15×12—retouch that, and then from it reduce to the size desired. By this means better results were obtained than by making the negatives from transparencies made by contact printing, as they were less like reproductions.

The only objection that can be raised against this system of producing enlarged negatives is that it involves the cost of two large plates; but surely that is not a serious item for consideration in sizes up to 15×12 or 18×15, and amateurs seldom exceed those sizes in their enlargements when the scope for improving in ultimate results is taken into account.

**Orthochromatic Photography.**—M. H. Bellieni writes an interesting letter to the *Moniteur de la Photographie* concerning the value of orthochromatic photography in deciphering documents. M. Arnould, the owner of some land at Bonzey, was a bachelor. A tenant, with a large family, with whom he was on friendly terms, was looked upon as likely to succeed to the estate. The property was flooded, M. Arnould drowned, and his papers lost. The next-of-kin claimed the estate, and the tenant tried in vain to prove his right to the property. By accident a bundle of papers was found in the mud not far from the house. The documents were stained, torn, and saturated with dirt. They were handed over to the local photographers, who were unable to reproduce a trace of the writing. The matter was brought under M. Bellieni's notice, and he, with the aid of orthochromatic plates and a screen, succeeded in obtaining a legible photograph of the documents. The case was again taken into Court, and the tenant, by aid of the photographic evidence, was enabled to establish his right to the land. M. Bellieni has sent M. Léon Vidal copies of the two photographs on ordinary and orthochromatic plates. Another romance of real life is thus added to the list in which orthochromatic photography plays an important part.

**Flashlight Powder.**—Herr Gaedicke refers to an article, which appeared in the *American Journal of Photography*, upon Flash Powders, and was republished in THE BRITISH JOURNAL OF PHOTOGRAPHY, May 19, 1899, p. 313. It was stated that the compound patented by Gaedicke and Mische contained amorphous phosphorus, but was never sold commercially. Herr Gaedicke says both these statements are incorrect. Amorphous phosphorus was never recommended by them, but they did recommend sulphide of antimony to accelerate combustion. Their flash powder was sold in large quantities, but not with the addition of chlorate of potash, which was included in the original formula. Nitrate of potash was substituted, and, to avoid any possible risk in transmission through the post, the magnesium was packed separately.

**Light and Colour.**—The *Deutsche Photographen Zeitung* gives the following interesting table of the amount of light reflected by substances and colours, taking one as the unit of incident light:—

Black velvet .....	0.004	White sandstone .....	0.237
„ cloth .....	0.012	Bright blue .....	0.300
„ paper .....	0.045	„ yellow .....	0.400
Dark blue .....	0.065	„ green .....	0.465
Dark moist earth .....	0.079	„ orange .....	0.548
Dark green .....	0.101	Plain white paper (photo-	
Bright red .....	0.162	graphic) .....	0.700
The moon .....	0.170	Fresh snow .....	0.783
Deep yellow .....	0.200	Mirrors .....	0.823

These figures are based upon the physiological intensity of the reflected light from the objects when illuminated with white light, taking spectral D as the optical maximum of intensity; but, as the maximum of sensitiveness of an ordinary bromide plate is about  $F_{\frac{1}{2}}G$ , the colour of the object should be considered in relation to the plate, and not visually. To obtain the same density of deposit upon an ordinary gelatine plate as one would get for a given exposure upon light blue or white, the following exposure factors should be observed:—

Violet .....	about	4 times longer.
Green .....	2	„ „
Yellowish-green .....	20	„ „
Yellow .....	36	„ „
Orange .....	120	„ „
Red .....	1600	„ „

**The "Art Portfolio."**—We constantly hear complaints in this country of the keen competition of cheap German workmanship. It is therefore refreshing to read in the *Wiener Freie Photographen Zeitung* that this publication is causing some anxiety in Germany.

Dr. Eder exhibited a specimen of the *Art Portfolio* at a meeting of the Vienna Photographic Association, and drew attention to the method by which these photogravures were produced with a very fine screen. He predicted that the process would greatly influence the future of photo-mechanical work, as it could compete with collotype, &c. Herr Schrank was of opinion that the process was originally due to Klic, who invented it in England, and suggested that inquiries might be made, as Klic was now residing in Vienna.

## THE DIFFRACTION PROCESS OF COLOUR PHOTOGRAPHY.

(Nature.)

THE production of colour by photography has been accomplished in two radically different ways up to the present time. In one, the so-called Lippmann process, the waves of light form directly in the photographic film laminae of varying thickness, depending on the wave-length or colour of the light. These thin laminae show interference colours in reflected light in the same way that the soap bubble does, and these colours approximate closely to the tints of the original.

The technical difficulties involved in this process are so great that really very few satisfactory pictures have ever been made by it. The other, or three-colour process, has been developed along several distinct lines, the most satisfactory results having been produced by Ives with his stereoscopic kromskop, in which the reproduction is so perfect that, in the case of still-life subjects, it would be almost impossible to distinguish between the picture and the original seen through a slightly concave lens. The theory of the three-colour method is so well known that it will be unnecessary to devote any space to it, except to remind the reader of the two chief ways in which the synthesis of the finished picture is effected from the three negatives. We have first the triple lantern and the kromskop in which the synthesis is optical, there being a direct addition of light to light in the compound colours, yellow being produced, for example, by the addition of red and green. The second method is illustrated by the modern trichromatic printing in pigments. Here we do not have an addition of light to light, and consequently cannot produce yellow from red and green, having to produce the green by a mixture of yellow and blue. Still a third method, that of Joly, accomplishes an optical synthesis on the retina of the eye, the picture being a linear mosaic in red, green, and blue, the individual lines being too fine to be distinguished as such.

The diffraction process, which I have briefly described in the April number of the *Philosophical Magazine*, is really a variation of the three-colour process, though it possesses some advantages which the other methods do not have, such as the complete elimination of coloured screens and pigments from the finished picture, and the possibility of printing one picture from another. The idea of using a diffraction grating occurred to me while endeavouring to think of some way of impressing a surface with a structure capable of sending light of a certain colour to the eye, and then superposing on this a second structure capable of sending light of another colour, without in any way interfering with the light furnished by the first structure. This cannot, of course, be done with inks, since, if we print green ink over red, the result will not be a mixture of red light and green light, but almost perfect absence of any light whatever; in other words, instead of getting yellow we get black. Let us consider first how a picture in colour might be produced by diffraction. Place a diffraction grating (which is merely a glass plate with fine lines ruled on its surface) before a lens, and allow the light of a lamp to fall upon it. There will be formed on a sheet of paper placed in the focal plane of the lens an image of the lamp flame, and spectra, or rainbow-coloured bands, on each side of it. Now make a small hole in the sheet of paper in the red part of one of these spectra. This hole is receiving red light from the whole surface of the grating; consequently, if we get behind the paper and look through the hole, we shall see the grating illuminated in pure red light over its whole extent. This is indicated in fig. 1, where we have the red end of the spectrum falling on the hole, the paths of the red rays from the

grating to the eye being indicated by dotted lines. Now, the position of the spectra with reference to the central image of the flame depends on the number of lines to the inch with which the grating is ruled. The finer the ruling the further removed from the central image are the coloured bands. Suppose now we remove the grating

FIG. 1.

in fig. 1, and substitute for it one with closer ruling. The spectrum will be a little lower down in the diagram, and, instead of the red falling on the hole, there will be green; consequently, if we now look through the hole, we shall see this grating illuminated in green light. A still finer ruling will give us a grating which will appear blue. Now, suppose that the two first gratings be put in front of the lens together, overlapping as shown in fig. 2. This combination

FIG. 2.

will form two overlapping spectra, the red of the one falling in the same place as the green of the other, namely on the eyehole. The upper strip, where we have the close ruling, sends green light to the eye and appears green; the under strip, with the coarser ruling, sends red light to the eye and appears red, while the middle portion, where we have both rulings, sends both red and green light to the eye, and in consequence appears yellow, since the simultaneous action of red and green light on any portion of the retina causes the sensation of yellow. In other words, we have, in superposed diffraction gratings, a structure capable of sending several colours at once to the eye.

If we add the third grating, we shall see the portion where all three overlap illuminated in white, produced by the mixture of red, green, and blue light.

Three gratings with 2000 lines, 2400 lines, and 2750 lines to the

FIG. 3.

inch, will send red, green, and blue light in the same direction, or, in other words, to the same spot on the screen behind the lens.

Suppose, now, we have a glass plate with a design of a tulip, with

its blossom ruled with 2000 lines to the inch, its leaves ruled with 2400, and the pot in which it is growing ruled with 2750 lines, and place this plate before the lens. On looking through the hole, we shall see a red tulip with green leaves growing in a blue pot. Thus we see how it is possible to produce a coloured picture by means of diffraction lines, which are in themselves colourless. Those portions of the plate where there are no lines send no light to the eye, and appear black.

We have now to consider how this principle can be applied to photography. That photographs which show colour on this principle can be made depends on the fact that a diffraction grating can be copied by contact printing in sunlight on glass coated with a thin film of bichromated gelatine. The general method which I have found best is as follows: Three gratings ruled on glass with the requisite spacing were first prepared.\*

To produce a picture in colour, three negatives were taken through red, green, and blue colour filters in the usual manner. From these three ordinary lantern-slide positives were made. A sheet of thin plate glass was coated with chrome gelatine, dried, and cut up into pieces of suitable size; one of these was placed with the sensitive film in contact with the ruled surface of the 2000-line grating, and the whole covered with the positive representing the action of the red light in the picture. An exposure of thirty seconds to sunlight impressed the lines of the grating on the film in those places which lay under the transparent parts of the positive. The second grating and the positive representing the green were now substituted for the others, and a second exposure was made. The yellows in the picture being transparent in both positives, both sets of lines were printed superposed in these parts of the picture, while the green parts received the impression of 2400 lines to the inch only.

The same was done for the blue, and the plate then washed for a few seconds in warm water. On drying, it appeared as a coloured photograph when placed in front of the lens and viewed through the hole in the screen. Proper registration during the triple printing is secured by making reference marks on the plates. A picture of this sort once produced can be reproduced indefinitely by making contact prints, since the arrangement of the lines will be the same in all of the copies as in the original. The finished picture is perfectly transparent, and is merely a diffraction grating on gelatine with variable spacing. In some parts of the picture there will be a double grating, and in other parts (the whites) there will be a triple set of lines. Having had some difficulty in getting three sets of lines on a single film in such a way as to produce a good white, I have adopted the method of making the red and green gratings on one plate and the blue on another, and then mounting the two with the films in contact. It is very little trouble to multiply the pictures once the original red-green grating picture is made.

The pictures are viewed with a very simple piece of apparatus, shown in fig. 4, consisting of a lens cut square like a reading glass,

FIG. 4.

mounted on a light frame provided with a black screen perforated with an eyehole, through which the pictures are viewed. The colours are extremely brilliant, and there is a peculiar fascination in the pictures, since, if the viewing apparatus be slowly turned so that its direction with reference to the light varies, the colours change in a most delightful manner, giving us, for example, green roses with red leaves, or blue roses with purple leaves, a feature which should appeal to the impressionists. The reason of this kaleidoscopic effect

\* These gratings were ruled for us on the dividing engine at Cornell University through the courtesy of Professor E. L. Nichols.

is evident, for, by turning the viewing apparatus, we bring the eye into different parts of the overlapping spectra.

It is possible to project the pictures by employing a very intense light and placing a projecting lens in place of the eye behind the perforation in the screen. Of course, a very large percentage of the light is lost, consequently great amplification cannot well be obtained. I have found that sunlight gives the best results, and have thrown up a three-inch picture on a four-foot sheet, so that it could be seen by a fair-sized audience.

By employing a lens of suitable focus it is possible to make the viewing apparatus binocular, for similar sets of superposed spectra are formed on each side of the central image by the gratings, so that we may have two eyeholes if the distance between the spectra corresponds to the interocular distance.

It is interesting to consider that it is theoretically possible to produce one of these diffraction pictures directly in the camera on a single plate. If a photographic plate of fine grain were to be exposed in succession in the camera under red, green, and blue screens, on the surfaces of which diffraction gratings had been ruled or photographed, the plate on development should appear as a coloured positive when seen in the viewing apparatus. I have done this for a single colour, but the commercial plates are too coarse-grained to take the impression of more than a single set of lines. With specially made plates I hope to obtain better results.

PROFESSOR R. W. WOOD.

#### "SECCO," A NEW STRIPPING FILM.

Writing on the subject of film photography a few weeks ago,\* we remarked that "the field available for film photography is an enormously wide one, and, in our opinion, . . . good substitutes for rollable celluloid will always find ready acceptance at the hands of the public. . . . The conveniences of film photography to vast numbers of photographers are so great that commercial enterprise in supplying the demand can scarcely meet with an unfavourable response for years to come." Secco film, which is just about to be placed on the market, appears therefore at a most favourable moment.

Those of our readers who are interested in the details of manufacture of the new stripper are referred to our pages of March 3 last, where the process is minutely described by the inventors in their Patent specification. Our present object, however, does not concern itself with the system adopted in the preparation of the paper, but to inform our readers of the results of our observations at a demonstration of the new stripping film, which was given on Friday in last week at the studios of Messrs. J. H. Avery & Co., 164, Strand, W.C.

Secco is apparently a gelatine emulsion, coated on a thin paper support. The stripped negatives possess perfect flexibility; they do not stretch in the manipulations of development or subsequently, and a very simple test with a lighted match shows that the vehicle has no collodion in it. We examined with great interest a very large collection of stripped negatives that had been prepared for inspection. Nothing finer in the way of sharp, crisp, non-granular images could be desired. Moreover, it was shown that the Secco film obviates halation in a very marked degree. We do not hesitate to say that Secco film, judging by the results we saw, is qualitatively all that can be expected of it.

But what of the stripping process, and how is it likely to behave in the hands of photographers, amateur or professional? The process is simplicity itself. The developed, fixed, and washed-paper negative is squeezed film side down on to what may be conveniently termed a temporary paper support, also coated with gelatine. Thus your image is now backed up on each surface with a film of gelatine and paper. When the negative is dried, or before if necessary, the corners of the paper supports are gently turned back, and with the slightest possible pressure and all the ease in the world, the paper sheets strip off the gelatine, and there is your negative complete, to be handled in precisely the same way as one on celluloid. We ourselves repeated the stripping process several times with perfect success; indeed, in all our experience, we never found a stripping paper work so easily and with such certainty.

Secco film has only to do in the hands of photographers what it did in ours on Friday afternoon last to be assured of a great popular vogue. We repeat that the demand for such a film is practically inexhaustible. The paper is at present sent out in cut sheets, but its adaptation to

rollable purposes will follow as a matter of course. It is not necessary for us to inform the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY what the advantages of a gelatine stripping film of the nature of that above described are in practice. We should say that ordinary pyro-ammonia development was adopted in the demonstration we witnessed, and a final bath of glycerine was employed. Nothing could be simpler, or, apparently, more certain than the working of Secco films, which, finally, do not curl in the solutions, and all through the manipulations behaved in a manner which was above reproach.

In reference to the foregoing, Messrs. Whitney, Graaff, & Co., of 39, Lombard-street, E.C., write: "Referring to our correspondence re 'Secco' films, we have pleasure in informing you that we have decided to demonstrate the advantages of same before any photographic societies that may be interested, and have arranged with Messrs. J. H. Avery & Co., of 164, Strand, to give demonstrations when and where required."

"We should be glad if secretaries of societies, wishing to have a demonstration, would communicate direct with Mr. Avery, when the necessary arrangements would be made."

#### ON SOME PHOTOGRAPHIC PHENOMENA CONNECTED WITH THE COLSON-RUSSELL EFFECT.

[Re-printed from the *Chemical News*.]

##### INTRODUCTION.

COLSON, who has for several years been publishing papers on the effects of various agents on a photographic plate, first found that heat in presence of moisture from paper, &c., was able to so affect a photographic plate as to cause a darkening of the sensitive surface when the plate was treated with a developer (*Comptes Rendus*, Jan. 1896, cxiii. 598-600). Colson subsequently found that the air in the neighbourhood of some bright metals possessed a similar property (*Comptes Rendus*, Jan. 1896, cxiii. 49-51). This he attributed to the action of the vapours of the metals themselves.

Russell discovered both these effects quite independently a little later, and in a series of papers (*Chemical News*, lxxv. 302; 1898, lxxvii. 167, *Proc. Roy. Soc.*, xiii. 102; lxiv. 409) has shown that both classes of effect are probably due to the same active agent. This agent is, in his opinion, hydrogen peroxide, and he has obtained chemical tests for the presence of this body in all cases in which the plate has been darkened by the emanations under discussion. The chemical recognition of hydrogen peroxide is a matter of great difficulty and uncertainty, and the probability of the truth of Russell's theory rests more securely on the perfect analogy which he has shown to exist between the behaviour of the vapours from active bodies and that of hydrogen peroxide. The completeness with which this similarity in properties is exhibited is remarkable, and can hardly be capable of any other interpretation than that of the identity of the active agents.

It must be borne in mind, however, that another explanation of the photographic activity of metals like zinc has been put forward by von Lengyel (*Wied. Ann.*, 1898, lxxi. [5], pp. 1162-1170), who looks upon hydrogen as the active agent. According to this author, hydrogen has an effect on a photographic plate similar to that of light, producing a modification of silver bromide, which is reduced by an ordinary developer. Russell, however, states in his first paper that, in an atmosphere of hydrogen, the action takes place as in ordinary air. This means that the effect of the hydrogen itself was so slight as not to be noticed by Russell, in comparison with the effect of the active bodies he was investigating.

The work of Russell shows that the dry plate furnishes a means to distinguish between hydrogen peroxide and ozone, as the latter does not affect the film. But, in making use of this test, the action of ozone upon any substance in the neighbourhood of the plate must be considered. It is the object of this paper to show that some bodies, which, although perfectly inactive previously, become strongly active when treated with even small quantities of ozone.

##### EXPERIMENTS WITH INDIARUBBER.

Indiarubber, as Russell has proved, is an inactive substance; that is to say, it may be put in contact with a photographic dry plate for a week or so without exerting any effect on the plate capable of causing darkening on development; but, if ozonised air be allowed to come into contact with the rubber for only a short time, it becomes so active as to give a picture in a few minutes. The effect may be heightened by passing the ozonised air over the indiarubber in a gentle stream. In this way, five minutes' ozonising and five minutes' exposure of the plate are quite sufficient to give a dark picture when Ilford special rapid plates are used.

The mode of experimenting may be varied as follows: A box of lead was taken and a sheet of rubber stretched over the top; this rubber was held in position conveniently by the lid of the box, also of lead. Two tubes of the same metal are provided for the entrance and exit of air and these tubes have their openings beneath the rubber diaphragms. The tubes are bent so as to render the box light-tight (fig. 1). If, now, a plate

\* THE BRITISH JOURNAL OF PHOTOGRAPHY, May 19, 1899, p. 305.

be put into the box with its sensitive film facing the surface of the rubber, and a coin or piece of glass or quartz be placed upon it, no picture is obtained by passing ordinary air through the apparatus; neither is any picture obtained if ozonised air be used and the rubber be absent. If, however, ozonised air and rubber be used, a picture is easily obtained in a few minutes. The effect is not one of light, since the quartz and glass appear equally opaque to the effect as the metals.

The rubber, on testing, is found to be photographically active either before or after removal from the box. The activity persists for some days afterwards, even when the time during which ozonised air has had access to it has only been a few minutes. The action of ozone on rubber is well known as regards its physical effects. If rubber tubing be used to convey ozonised air, it rapidly becomes so changed that, on slightly stretching it, it breaks up in transverse rings. The action is well shown on photographs of rubber sheeting obtained by contact in the dark. If the ozonisation has been continued so long as to have caused the rubber to break, the broken edges are beautifully distinct on the photograph.

This indicates that the activity of the rubber arises from some product of the action of ozone on the rubber itself, as distinct from any action that may occur between the ozone and the water or other bodies present.

The effect of ozonised rubber is probably due to the formation of hydrogen peroxide. Indiarubber yields on distillation, at moderate temperatures, bodies such as isoprene, more or less allied to the terpenes. Thus it seems possible that rubber itself consists largely of bodies chemically related to the terpenes. The latter are well known to yield hydrogen peroxide on oxidation, and Russell has shown that all the terpenes are photographically active.

Mr. Bryan was good enough to test some rubber sheets in his apparatus for investigating the effect of bodies on the contact difference of potential between two metals. He found that rubber itself had no influence, while ozonised rubber and rubber exposed to the vapour of hydrogen peroxide had an effect in the same sense. This result is not properly to be interpreted by remarking that ozone and hydrogen peroxide both affect the rubber similarly, since hydrogen peroxide apparently has no chemical action on rubber. It rather shows that hydrogen peroxide is a product of ozonisation of rubber.

#### TRANSFER PICTURES.

If a plate, after being subjected to the influence of the ozonised rubber, be placed upon another plate before development, then, after the films have been in contact some time, the picture may be developed on both the plates. Thus these pictures can not only be taken, but also in a sense printed, in the dark. Professor J. J. Thomson informs me that Russell has also obtained such pictures; a similar phenomenon is mentioned in Russell's papers, in which the first photographic film is replaced by a non-active body capable of transmitting the effect. This capacity of printing transfers is of use in satisfying the experimenter that any particular effect is not due to radiation of any type. Such transfer pictures have been said to be capable of production by light. But the universal practice of photographers is to store exposed plates film to film before development. No such phenomenon ever occurs as the one exposed plate affecting the other. Another reason for thinking that any such effect is absent is found in the total lack of any accumulative continuing action of light on a photographic dry plate. Experiments to obtain transfers with dry plates and daylight were carried out, both with normal exposures and also with exposures producing solarisation, but not the slightest effect could be obtained. These remarks do not apply to the bichromate processes in which continuing action does occur (Vogel, "The Chemistry of Light and Photography," 1875, p. 242), as is well known, and transfer pictures by contact in the dark can be obtained (THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1899, p. 822).

The active agent from ozonised rubber passes through paper, gelatine, tracing paper, &c., in the same way as with Russell photographs; and bodies like the metals, glass, and quartz are opaque to it.

#### SENSITIVENESS OF THIS TEST FOR OZONE.

The amount of ozone necessary to obtain these pictures seems to be very small; for, if the positive or negative brush discharge from a small Wimshurst machine be allowed to play on a disc of metal, with a central aperture leading through one of the lead tubes to the box in the apparatus above described, the pictures can be obtained in an hour, even without drawing the ozonised air over the rubber. The ozone necessary reaches the rubber by diffusion only.

#### TESTS FOR $H_2O_2$ .

A glass tube, two feet long and an inch wide, was loosely packed with shreds of pure rubber. Ozonised oxygen, after passing through the tube, was photographically active. The rubber was then washed with water, and the latter gave the tests for  $H_2O_2$  with chromic acid and titanic acid. This water was also exceedingly active photographically; a plate placed a quarter of an inch from its surface gave a good picture in ten minutes, while painting the liquid on to the plate produced solarisation almost immediately.

#### EXPERIMENTS WITH OTHER BODIES.

The common varieties of gutta percha also become fairly active on ozonising; but pure gutta percha becomes only slightly active, so as to require ozonised air to be in contact with the sheet for a quarter of an hour, and a subsequent exposure of the plate for half an hour, in order to obtain a picture capable of development.

It is interesting to note that camphor also becomes active by treatment

with ozone. In experimenting with bodies other than rubber it is best to use oxygen instead of air, as this is an economy of time. On ozonising camphor for ten minutes, it becomes active enough to give a good picture with a quarter of an hour exposure. As Russell has previously shown, camphor, indiarubber, and gutta percha are ordinarily quite inactive, though capable of transmitting the active agent.

Those other bodies (including cork, vulcanite, and gelatine) which have been tested with ozone are either inactive or else the effect is much less than in the above cases.

Cavendish Laboratory, Cambridge.

#### PHOTOGRAPHY IN THE ARGENTINE.

At the Royal Photographic Society's *Soirée*, the other night, were a very fine collection of portraits by Mr. A. S. Witcomb, of Buenos Ayres, kindly lent by Don Dominguez, the Argentine Chargé d'Affaires. Unfortunately, through their late arrival and their being unframed, only a few could be shown. The pictures were sent here at the request of the Committee appointed by the President of the Republic, not for sale, but to embellish the Argentine stall at the recent bazaar at the Albert Hall. Previous to the pictures—about sixty, single figures and groups from 20 x 16 downwards—being received at Russell-square, we had the opportunity of examining them, and we may say that we have rarely had the pleasure of seeing so fine a collection. The prints were all on matt-surface, collodio-chloride paper of, we are told, Mr. Witcomb's own preparation, and they were of a rich black tone, unlike ordinary collodio-chloride prints. The Argentine is a long way off, but photography has put us in possession of the fact that there are very beautiful ladies in Buenos Ayres, and that they dress with exquisite taste; also that in Mr. Witcomb the Argentine possesses an artist who is not excelled by any on this side. When examining this fine work, one could not help feeling a certain degree of pride that Mr. Witcomb is one of our fellow-countrymen.

#### THE ILLUMINATION OF THE DARK ROOM.

(Paper read before the North Middlesex Photographic Society.)

THE question as to what is the light most suitable for illuminating the dark room in which the photographer manipulates his sensitive plates is one which concerns not only the excellence of his results, in their freedom from fogging due to excess of light, and from faults due to the difficulty of working in insufficient light, but there is, as well, the effect of continued strain upon the eyesight and nerves when working in such a light as is commonly used by photographers. It is because I think there is still considerable misapprehension on the subject that I propose now to discuss it.

In one of the few recent articles in which this matter has been referred to it is mentioned that there seems to be a general consensus of opinion in favour of a ruby light rather than one of a yellower colour, and it is suggested that the exacting character of modern plates is responsible for the preference. My own view is that, ruby light having been originally insisted upon in instructions for working gelatino-bromide plates, these instructions have since been followed, and the necessity of ruby-coloured light has been accepted as a fact, owing to

the circumstance that photographers are not in the habit of making those careful comparative experiments, without which mere opinion ought to have no authority.

How it arose that red illumination was selected for bromide plates was due to two circumstances. In the first place, certain laboratory experiments had indicated a greater relative sensitiveness to green and yellow with bromide than with iodide of silver. When, however, gelatino-bromide of silver plates were compared with the ordinary wet-collodion in the camera, by photographing ribbons of various colours, as was done by the late J. R. Sawyer and afterwards by myself, it was not found that the yellow relatively to the red was more photographically active with the gelatine than with the collodion plate. The other circumstance, taken as indicating the necessity for ruby light for the dark room, was that photographs of the spectrum were produced, in which, with a strong action in the violet and blue, there was a slight action in the green and yellow, ceasing entirely in the red. A spectrum photograph of this kind was recently shown at the Royal Photographic Society in illustration of a lecture on orthochromatic photography, but a question elicited the explanation that the photograph was only to be taken as illustrating a particular length of exposure, and that a longer exposure would have caused the red to impress its image on the plate along with the rest of the spectrum.

The inference which naturally followed from consideration of these spectrum photographs was that, if the photographic action ceases in the red, as for the most part they represented it to do, or if the red is the least photographically active portion of the spectrum, as is the fact, light of that colour is the most suitable for working with when manipulating photographic plates. This inference must be, however, considerably qualified when it is remembered that the red is also much less luminous to ordinary eyes than is the yellow and the region near it on either side. The question then becomes the somewhat more complex one, What is the light which, when used in sparing quantity, will give the most visual illumination compared with its photographic activity? I have said when used in sparing quantity, because a further complication arises from the fact that, when lights of different colours are judged to be of equal luminosity when strong, this equality disappears when the strength of the lights is equally reduced. Captain Abney some years ago showed an apparatus in demonstration of this fact. Red and green squares of bright illumination were adjusted so that their luminosity appeared to be equal, but, upon reducing the illumination, the green remained visible after the red had apparently disappeared, and this to an extent indicating several times as great sensitiveness of the eyes to the green rays as compared to the red when both were feeble, as they had when both were strong.

The next point is the effect on the eyesight and nerves of continued working in light of particular colours. Here, of course, there will be great differences in different individuals, but I believe it is quite general to feel considerable strain after working for a time in red light. Mr., now Sir Henry, Harben, an enthusiastic amateur photographer, whose dark-room windows I changed from ruby to yellow by the aid of pale yellow-green glass and several thicknesses of yellow paper, told me that after an hour or so of the red illumination the eyes were so fatigued that he could not, after leaving the dark room, either read or do anything requiring the use of the eyes. After the change in the dark-room lighting, however, he was able to go direct to any other occupation without feeling any ill effect. One of the leaders of photographic thought tells me that with him the effect of red illumination is to induce nervous strain. On the other hand, the most unanswerable argument in favour of red light was brought forward by Mr. Andrew Pringle, who said that red light was agreeable to him, and greenish light the reverse. I think, however, his is a very rare case, but those who happen to have a similar peculiarity may, of course, do well to use a red light.

The case of orthochromatic plates may require some special consideration. The so-called orthochromatic and isochromatic plates which are sensitised for green and yellow, and not at all for red, may be best developed in a red light, although I have developed them in my yellow dark room without perceptible injury. For plates, however, which are really orthochromatic, red would be a very unsuitable illuminant, owing to its feeble luminosity when reduced in quantity, as has been already mentioned.

It is now recognised that the effect of yellow is produced by the excitation both of the red sensitive and of the green sensitive nerves in the eye. The division of the work of seeing between two sets of nerves, instead of being all thrown on to one set, has probably more to do with the greater comfort of using yellowish light than the less irritating effect of green as compared with red. The light may even be principally red, as is the case with orange, and still be less trying to the sight than is ruby alone. The effect of yellow may be produced either by spectrum rays about the D line, which affect both sets of nerves, or by the combination of red and green rays as effected by throwing overlapping discs of these colours from two lanterns on to a screen. The comparative luminosity and photographic safety of these yellows has not, so far as I am aware, been made the subject of any complete research. Concerning the mixed method of production I shall have something to say presently.

The use of light reflected from a coloured surface has been praised, and, it appears, justly so. Many years since, Mr. Warnerke described a

lamp which was fixed in the ceiling, and had a dome painted inside with vermilion. At the bottom of the lamp was a sheet of ruby glass. Mr. Cowan, some time later, showed a lamp of the safety and luminosity of which he gave a very high character. The back of the lamp was curved in a semicircle, and was lined with yellow paper. The front was glazed with glass of a greenish-yellow colour. In the middle was a gas jet which illuminated the yellow back, and a disc of tin was so placed as to prevent any of the light from the flame coming direct through the glass front. A lamp which gave me the greatest safety in comparison with its luminosity was one which I showed at the Photographic Society of Great Britain some years ago, and the light from which the then President, Mr. Glaiher, spoke of as white, though that, of course, would not be in comparison with daylight, but with gaslight as seen through various media. The back of this lamp was concave, or rather semicircular, and lined with yellow paper. On either side a lamp was boxed in, the side of the box facing the yellow paper being filled in one case with a green, and the other with a red, glass. Between the boxed-in lamps a space of about ten inches wide and fourteen inches high allowed the light from the yellow paper to shine through and illuminate the work-table. Details of some experiments with this lamp, in one of which Mr. W. K. Burton took part, were published at the time. A further security was obtained by covering the front with a single thickness of golden fabric. Both lamps might be fitted with ruby, and even then the light would not, I think, have the same trying effect as that coming direct through the ruby glass, though this is an experiment which I have not made.

It must not be forgotten that no light which enables us to see is free from effect on a sensitive plate, and therefore, whatever illuminant is used, the plate should not be exposed to it longer than necessary. A simple plan in a prolonged development is to have a window of, say, fifteen or eighteen inches in height, close down to the sink or work-table, and to raise the dish out of the direct rays, lowering it occasionally for inspection as may be necessary. I think, however, that with the lamp I have described the safety is so great that there should be little risk, with ordinary care.

W. E. DEBENHAM.

## FLORAL PHOTOGRAPHY.

### I.

For many years the photographing of flowers and various plants has been confined to only a few workers, who, perchance, may have had more than ordinary facilities of acquiring suitable subjects for this class of work; but, now that one of the leading horticultural societies in the United Kingdom has decided upon holding an exhibition of photographic work in connexion with its important Autumn Flower Show in the West of Scotland, arrangements for which Exhibition are in the hands of several of the best-known workers in the district, it is safe to assume that something like a fillip will be given to floral photography, not only in and around Glasgow, but likewise throughout the entire United Kingdom. It is almost certain other kindred societies will not be slow to take a leaf out of the book of the Glasgow and West of Scotland Horticultural Society, who may be said to be the first to move in this matter, and already quite a number of amateur and professional workers have signified their intention of contributing to the forthcoming display in St. Andrew's Hall.

The first important step in work of this kind is the selection of suitable subjects. These, it may be said, are only attainable at certain seasons of the year, as every one knows; but, during every month, from early spring onwards, there will be found plenty of delightful subjects that are specially amenable to photography. In springtime we have our crocuses, hyacinths, daffodils, tulips, lilies of the valley, snowdrops, and many other of the early flowering bulbs, all of which yield charming studies, especially the daffodils and lilies of the valley, these being followed by the early summer blooms, which are, again, in turn found giving place to multitudes of later summer and early autumn flowers; from which any one who feels inclined to give a little study to this class of work will be able to gather together an abundance of subjects for his camera—indeed, far more than he will ever be able to undertake in his spare moments.

As to the selection of subjects, these may be divided into three or more sections. First in importance undoubtedly stands cut flowers. These, it may be said, are at every one's control, even those not possessing a garden or greenhouse of their own. Secondly, in pot plants there will be found an unlimited field for selection, and these and the previous section are at all times capable of being placed in any desirable situation for being photographed; and, thirdly, we have almost as unlimited a field to work upon in flower-beds and borders towards autumn, that, if slightly more difficult to deal with in the way of photography, yield, when properly treated, charming results.

One of the first essentials in dealing with cut flowers and pot plants is a suitable background. This adjunct must be carefully studied, and it will be found, from among the many hues met with on the blooms, that a slight alteration in the tint of a background works wonders in the relief it is so desirable to attain. All those of a white hue are best relieved with a dark, but not absolutely black, colour in the background, for, in the writer's experience, this tends to the production of hard results, savouring

too much of the soot-and-whitewash description. Any one not having much experience in this work might imagine that the obtaining of backgrounds of varying colours means a serious outlay and expense, and thereby be deterred from undertaking this delightful branch of photography; but, in reality, such is not the case, for a few shillings at the outside will go a long way in supplying quite a large stock of various tinted backgrounds suitable for the work. As a rule, these backgrounds are not required to be of large size, a square of about four feet being a suitable and handy size for most ordinary work. A web of brown and thick white paper does not cost much, and an old broom handle or two can generally be picked up in most households. With these provided, the paper can be cut to any lengths, and glued after the fashion of a map to the broom handle. In this condition the paper can be colour washed to any tint that is desired, the pigment being mixed with a little size, or glue, or gelatine. For extremely close work, where minute subjects are to be rendered in their natural size, such as would be the case with pansies and violas, small backgrounds of velvet or grey-tinted, smooth, but not glazed, paper should be brought into requisition. The distemper tint, however, may be easily made and applied to a paper surface by mixing with ordinary whiting, size and water, a little lamp-black, which must be first mixed in water by itself until it forms almost a thick paste, and quite free from grit or small lumps. This black colour is then added, drop by drop, to the whitewash until any desired shade of grey is reached, it being borne in mind that the colour washes invariably dry a shade or so lighter in tint than it appears when wet. If a dark-brownish tint be desired, it is produced by adding a much greater quantity of lampblack, to which must be added a little burnt sienna powder mixed in the manner previously described for the lampblack, the chief point being always to add the colouring matter in liquid form. When a few of such backgrounds have been acquired, they may be altered from time to time if their tints do not happen to suit the particular subject being treated, and, if two or three rough but stout frames of about four to five feet square be provided, any background may be stretched thereon drum-tight before being colour-washed.

One of the most useful backgrounds the writer possesses, and which he has used for many years when photographing various plants and flowers for book illustration, is merely a long roll of brown paper; this is placed on the floor from the foot of the studio camera stand and extends to the wall in a curved form. The pot plant is placed on the top of the paper, standing on the floor, or sometimes, when a higher elevation is desired, on a small platform, and by this means the entire plant is shown standing upon its support, and the cut off through the middle effect, so often seen in this class of work, is avoided. A background of this description will enable a plant being photographed from any angle or point of sight—a matter of no small importance, when it is desired to look somewhat down upon the plant. Very many subjects will be found to yield charming results by placing them *in situ* on the floor of the studio and rearing the camera straight overhead. When this treatment is resorted to, it will be found that a special piece of apparatus is required to hold the camera in this vertical position; but this is easily made by any one possessing a couple of flat boards about half an inch thick and slightly larger than the tail-board of the camera. These are hinged together after the manner of a printing-frame back, a hole being bored through the centre of one to enable the camera screw being inserted, the other board clamped to the edge of a rough table or similar contrivance, and the two flaps nailed at their proper angle by means of a stout wooden guy rod. This enables a camera to be placed vertically over such subjects as a large assortment of cut flowers, which will be found to yield a charmingly natural position when such are, to a certain extent, indiscriminately gathered together and dropped upon the floor.

In work of this kind, amateurs especially will find the absolute need of having well-made, suitable cameras. Over and over again, in the pages of THE BRITISH JOURNAL OF PHOTOGRAPHY, the writer and others have urged upon beginners the need of showing some discrimination when they purchased a photographic outfit. Years ago a well-made camera was recognised to be square both at back and front without any tapering, and no rack-and-pinion focussing arrangement was permissible, but all this has, within the last fifteen years, changed, and utility has almost entirely been sacrificed to portability. This we see painfully evident in the slim, tapered rack-and-pinion camera puzzles, with their brass kick-shaws and invisible springs with which a modern camera is now furnished. These cameras are unfit for very much useful work, and the branch of photography to which we are now referring, and which undoubtedly will, in the near future, become highly popular, is just one of the tests where a modern camera is tried and found wanting.

In vertical photography it very frequently happens that the camera has to be elevated so that the lens is exactly above the objects, and further, it is by no means uncommon that this can only be acquired by stagings which permits of the camera resting on its front, through a slot or hole in a board, the dark slide being on top of all, thereby adding considerably to its weight. Now, the uselessness of the rack-and-pinion form of focussing attachments will soon be evident and the immense superiority of the good old screw-rod attachment, alas! so seldom met with now, becomes an actual necessity. Were Judges at our Exhibitions where apparatus is displayed to show more judgment in their awards, and only recognise such form of cameras and other photographic

apparatus as are really of practical all-round utility, it would save much annoyance to many beginners, who, for the time being, are really not aware of the shortcomings of the apparatus they are acquiring.

In floral photography, where vertical adjustment of the camera is so often required, the rack-and-pinion focussing adjustment will not support the weight of a dark slide where any fairly large size of plate is used, and such cameras may be set aside as useless for all classes of photography where vertical adjustment is required.

T. N. ARMSTRONG.

## ILFORD PLATONA PAPER.

[Photographic Scrap.]

ILFORD Platona Paper, recently received from the Britannia Works Co., is a new platinum paper which will be welcomed by all those who desire to produce photographic prints that are not only highly artistic in appearance, but also have the great merit of being as permanent as the paper on which they are made. Since also the price at which it is offered is comparatively low, it seems not unlikely to lead to a considerable increase in the number of workers in platinotype.

The paper may be obtained in sheets or in various cut sizes and is put up in tins provided with a very convenient form of screw lid, fitted with an indiarubber washer that makes a practically air-tight joint when the lid is screwed down. After it has been opened the tin still serves for the safe storage of the paper that has not been used, and also as a receptacle for exposed but undeveloped prints.

Each tin as sent out contains a lump of calcium chloride for the purpose of keeping the contents quite dry. When the tin is first opened, it is advisable to take the calcium chloride out and leave it out, relying on the screw lid and washer to protect the paper left in the tin from the action of atmospheric moisture. To attain this end, care should be taken to screw the lid tightly down.

The paper is coated with a mixture of a ferric salt and a platinum salt, and the sensitised surface has a bright lemon yellow colour. In the samples that I have examined the coating was very uniform and the paper was free from any mechanical defects.

With Platona paper, as with any other platinum paper for development, success depends to a large extent on keeping the paper dry both before and during use, and also between exposure and development. It is important therefore that the pads of the printing frame should be quite dry, and it is advisable to place between the pad and the Platona paper a sheet of some waterproof material such as Willemsen paper, the oiled paper used in letter-copying presses, or thin sheet indiarubber. This precaution should be regarded as indispensable, especially during damp weather.

During exposure the yellow colour of the paper changes to dark purple-violet, and ultimately to dark orange when the maximum possible effect of light has been produced. The process is only partially a print-out process and the image on a properly exposed but undeveloped print is not very deep or distinct. To correctly estimate the exposure is the only difficulty that the process presents besides that of keeping the paper dry, and it is a difficulty that soon disappears with a little practice.

The undeveloped Platona print should show all the details in the shadows and the main details in the half-tones, but not the details in the lights. Care must be taken to examine the prints in weak light only.

After exposure the prints are developed by floating them on or immersing them in a solution of potassium oxalate and phosphate. The following formula, recommended by the Britannia Works Company, answers very well:—

Potassium oxalate .....	2 ounces.
Potassium phosphate .....	$\frac{1}{2}$ ounce.
Water.....	14 ounces.

The solution is most readily made by using hot water, and can be kept for any length of time. For use, a part of the stock solution is diluted with an equal quantity of water and placed in a clean porcelain dish. The prints are floated face downwards on the surface of the liquid, or may be immersed in it, taking great care in either case to prevent the formation of air bubbles or to remove them if they should form. The faint image begins almost at once to change to black and to become more intense. When development is complete, the prints must *not* be washed with water but must be placed directly into a clearing bath of dilute acid to ensure complete removal of the iron salts from the paper:—

Pure hydrochloric acid .....	1 ounce.
Water .....	80 ounces.

Place some of the dilute acid into three porcelain dishes, which we will refer to as Nos. 1, 2, and 3. The developed prints are placed in No. 1 and kept moving for about five minutes, they are then transferred to No. 2, and again kept moving for about five minutes, after which they are placed in No. 3 for five minutes and are finally well washed in running water, or in frequently changed water for about fifteen minutes. They are then dried.

It will be observed that the manipulations are very simple and occupy comparatively little time. If necessary, the drying of the prints can safely be accelerated by heat.

I have made a number of prints on Platona paper from negatives of

different kinds with uniformly satisfactory results; the colour is good and the gradations and the rendering of detail in the high lights are excellent.

Platona paper, like all other platinum papers, requires good negatives in order to get the most satisfactory results; they must show good contrasts with a considerable amount of detail in the shadows. Negatives that give first-class prints with the ordinary P.O.P. will also give first-class prints on Platona paper, whilst negatives that are very strong in contrast will give better results on Platona than on P.O.P.

Platona paper, therefore, affords a method of obtaining rapidly, and after a little practice, easily, prints of a kind that are usually recognised as being very pleasing and artistic in character, with the added merit of the maximum degree of permanence possible in photographic prints.

C. H. BOTHAMLEY, F.I.C., F.C.S.

#### ACTINOGRAMS, AND A SELF-RECORDING ACTINOMETER.

By "actinogram" I understand a record of the actinic value of a source of light traced upon a sensitive surface, such as silver-chloride paper or a silver bromide and gelatine film. Roscoe was one of the first to obtain these tracings, and at one time some extensive observations were undertaken at Kew, and by Captain Abney at South Kensington. The actinograms were made by the aid of Roscoe's actinometer, an instrument consisting of a revolving drum carrying a silver-chloride paper, with a driving-clock so arranged that at stated intervals small portions of the sensitive paper were exposed to light, for times ranging from a few seconds up to several minutes. At the end of the day the exposures were compared with a standard tint, and the strength of the light estimated from the depth of colouration. Abney also devised a rotating cylinder, with alternate black and white sectors, to facilitate the reading of the tints.

The actinograms obtained under these circumstances were intermittent, of the same nature as a series of individual readings, and like them, when extending over a long period, liable to fail at such times as to

tions based on matching one tint against another, the readings can be depended upon only within somewhat wide limits, and do not admit of that precision which a scientific method demands.

Since these early experiments of Roscoe, important advances have been made which render it possible to obtain actinometric records of much greater exactitude. I refer, firstly, to the introduction of rollable gelatine films; and, secondly, to Abney's work on measuring the transparency and opacity of the photographic negative. In my opinion these have an application to this subject which enables us to carry forward the work of early investigators, that has of late years been much neglected.

From these observations it may be gathered that the actinometer described below attempts to achieve a continuous record of daylight, or other source of illumination, and to establish with greater accuracy variations in the intensity of light than is possible with silver chloride, or other system depending on matching tint against tint.

Fig. 1 is a general view of the actinometer. A is a drum twelve inches in circumference, and six inches in length; attached to the driving-clock, B, and so designed that it revolves, without drag or start, once in twelve hours. C is a light-tight box to carry the drum and clock, in the lid of which is an opening, D, six inches in length, and so placed as to fall along the top of the drum when enclosed in the box. In this opening is fitted a scale of densities. The width of the slit must be regulated in accord with the length of exposure desired. The one I have in use is a quarter-inch wide, giving an exposure of a quarter of an hour, since the drum rotates once in twelve hours. The apparatus was made by Messrs. Watson & Sons, to whom I am indebted for several valuable suggestions.
